We are now upon the very threshold of Mrs. Hughes's voice figures of which I have spoken *in extenso* in a previous communication, but for the sake of completeness I will recapitulate some of the important points set forth therein. She has reached the path which brought her to them by the phoneidoscope. Her eidophone is constructed on the same principle as the phoneidoscope; in eidophone, instead of the frail lamina of soap-suds, she has a stretched membrane of india-rubber to receive the vibrations, and on this is spread a thin layer of some pasty substance which will retain the record made by the vibrations of the membrane. These voice-flowers are not the simple, visual forms corresponding with the vibrations of the air set in motion by the voice. The waves generated in the closed bowl of the eidophone are reflected again and again from the sides of the vessel. The volume of air inclosed has its own rate of vibration; the stretched membrane has also its own rate, which in turn is modified by the character and thickness of the paste spread upon it. Added to these are molecular forces of cohesion and adhesion between the particles of paste, and again between the paste and the membrane. The form which grows into shape is the resultant of all these complicated forces, and, in some instances, new elements of change have been added. A glass plate is placed on top of the vibrating membrane and moved over it. We have a new body introduced with its proper rate of vibration, besides a mechanical motion further to complicate the problem.

The results are very wonderful and beautiful, and open up a field for investigation which is most interesting; but so far we have the resultant of many forces, not one of which has been weighed and measured. In a letter, Mrs. Hughes, replying to some questions asked in the hope of greater accuracy, says: "The notes producing the figures vary necessarily with the weight of material used and the tension of the membrane, so that any one note may, under different circumstances, produce different figures, and conversely, different notes may, under different circumstances, produce similar figures."

The daisy forms (Fig. 3) were sung into shape, she says, by extremely low notes, very softly sounded, some of them by A in the first space of the bass clef—a wonderful note to be reached by a woman's voice, whose highest note is the B flat above the treble clef, a compass of over three octaves. Sometimes geometrical forms, not given in the illustrations, were produced by the highest notes of her voice, while the serpent, fern, and tree forms were made by singing her middle notes with great intensity.

Among some of the first experimenters of hearing with the eyes, were Messrs. Lissajous and Duhamel, whose researches in that line are known to all of us. The more recent men who worked in this field are Leon Scott and Dr. Koenig. The first is the inventor of the phonautograph, whose instrument gave a more comprehensive sound-writing; and the latter for making sound visible by a compound series of flames produced by a single burning jet connected with two or more tubes, and combined with a series of resonators. This has been exceedingly serviceable in the elucidation of those obscure qualities of sounds, of which he was enabled to distinguish different voices and instruments, even when the pitch and intensity of the notes are the same.

It is useless to dive into the minute description of those apparatuses, etc., as they may be found in all works on modern physics.

Early last April I had occasion to apply the principles demonstrated by the work of Chladni and Mrs. Hughes to another and highly important branch of our science. The result of these experiments will probably be made known to the members of this Congress by my colleague, the distinguished American physician, Dr. George Engleman, of St. Louis, with whom I was engaged in the task of bridling the faradic current and accurately measuring and calculating the number of interruptions of the faradic machines used by our electro-therapeutists, and observing the physiological action at the various rates of interruptions. Dr. Engleman, as I understand, will detail the exhaustive research he and I have made in this direction in the section of electro therapeutics or physiology.

By means of sensitive diaphragms and a dry powder, like lycopodium, I obtained visual pictures of regular geometric shape corresponding accurately to the number of breaks in the current. In this instance I employed a hollow cylinder about three inches in diameter and about six inches long, over which I stretched an elastic membrane. Upon the centre of this membrane a small part of dry lycopodium was dropped and the cylinder was placed upon the diaphragm of a telephone receiver, the open end next the diaphragm. With each change in the number of interruptions in the faradic current, the powder assumed a different geometric form, and we were thus enabled to calculate the number of interruptions with absolute accuracy as they ranged from 3,000 to 50,000, and as I have since learned, up to 102,000 per minute. Some of the figures resembling those of Hughes and Chladni.

When sonorous undulations impinge upon the delicate diaphragm of a phonograph the latter is set in vibration. Its particles move to and fro in some way or other. The complexity of their motion will depend upon that of the air from which it was derived. This brings me to what I have to say of the phonograph itself.

In the annals of modern inventions the phonograph (Figs. 4 and 5) and its inventor, Thomas A. Edison, will always occupy a foremost place. Years ago, had a scientist had the temerity to proclaim that he could record and reproduce human speech, the sounds of music, and other living tones, and preserve them for ages just as the pathologist guards his specimens from the ravages of time, he would have been proclaimed a

sorcerer and perhaps burned at the stake, as were the so-called witches in my own country only two centuries ago. How times have changed! I need not rehearse the early trials and tribulations of the illustrious gentleman, whose ideas crystallized in tangible form are before you. It would simply be a repetition of the fortunes of all the great observers whose work has become historic. He fought against almost insurmountable obstacles and overcame them. Let me briefly recount the story of the discovery of the phonograph.

Edison's early phonograph was founded upon the discovery, that if a delicate diaphragm or sounding-board is provided with a sharp point of steel, its vibrations under the sound of the human voice will cause the sharp point or stylus to make a series of impressions or indentations upon a sheet of wax or other analogous material passed beneath it. Such indentations, though microscopic, are sufficiently defined to cause similar vibrations in the diaphragm, if the stylus is again passed over the furrow of indentations, and this reproduction is loud enough to be distinctly heard. Thus, the phonograph, in its primitive form, consists of a little sounding-board carrying on its under surface a needle point, and a sheet of wax so held as just to touch the needle. The sound-waves of the voice cause the sounding-board or diaphragm to vibrate with a rapidity varying with the pitch of the note.

If the wax sheet was made to move slowly along while the sound-waves of music, talking, or singing were allowed to impinge upon the sounding-board, the result was found to be a continuous line of minute indentations, corresponding in depth and geometric form to the outline of the original sound-waves.

These lines were continued side by side, until the smooth surface of the sheet was covered over with indentations.

This done, on raising the stylus and the diaphragm and again placing it in the first furrow of indentations, the stylus, as it travelled through the series of lines, caused the sounding-board again to vibrate, sending out an exact repetition of the sounds as they were originally impressed in the wax; although somewhat changed in pitch, intensity, and quality, they were yet of sufficient accuracy to demonstrate the possibility of recording and reproducing living sounds.

Photographs and measurements of these tracings of the sound waves on the wax cylinders, etc., were recently made by Hermann, of the Königsberg physiological institute, and are of great interest in the study of the phys ics of sound.

The defects of the first phonograph were so great that Edison found it impossible to interest capitalists in perfecting it. At the same time eminent men in Europe were not wanting, who predicted great things for the phonograph of the future. What it accomplished was so wonderful that inventors were tempted to work over it.

But the phonograph of to-day, the novel and remarkable instrument, has passed much of its experimental stage. It is now practically successful in every respect,

Fig. 3.—Showing Voice Figures of Mrs. Hughes—Produced by Means of the Eidophone.

and must be regarded as instrumental in opening up a new field for scientific research, and making one more application of science to industry. Its aim is to record and reproduce speech; to make a permanent record of vocal or other sonorous vibrations; to recreate these vibrations in such manner that the original vibrations may be again imparted to the air as sounds.

Notwithstanding all that has been said against the properties of the sounds reproduced by the phonograph, there is no doubt but that they are reflected in absolute integrity, but somewhat decreased in volume. In other

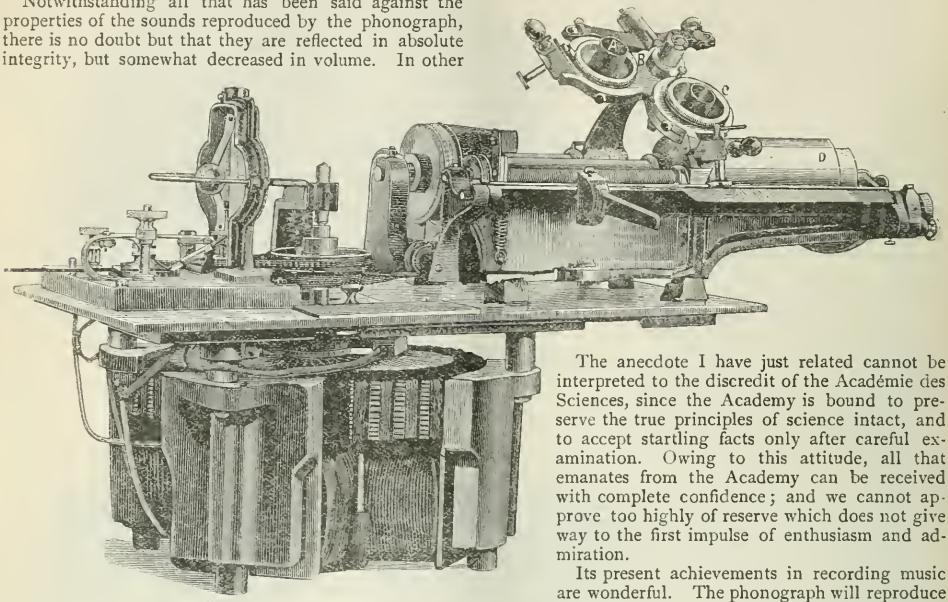

FIG. 4.

words, I mean to say that the record of a sound, as it is given out or as we hear it coming from the phonograph, is an exact miniature of the original. And this is easily explained if we bear in mind the fact that the diaphragm can only record those wave-pulses which are caught up and encompassed by the recording trumpet. The others lose themselves in space, yet the pitch and quality remain unchanged.

The phonograph is really a natural outcome of the telephone; but unlike any form of telephone, it is mechanical and not electrical in its action.

The following anecdote is told by M. Paskos, Mr. Edison's agent, who presented the first phonograph for exhibition before the academicians of Paris. It was a curious spectacle to witness the expression of the faces of these academicians when M. Paskos caused the wonderful instrument to speak. A murmur of admiration was heard from all parts of the hall, a murmur succeeded by repeated applause. The learned Academy, generally so cold, had never before abandoned itself to such enthusiasm, yet some members of a sceptical turn of mind, instead of examining the physical fact, ascribed it to moral causes, and a report soon ran through the room which seemed to accuse the Academy of having been mystified by a clever ventriloquist. Certainly the spirit of ancient Gaul is still to be found among the French, even in the Academy. One said that the sounds emitted by the instrument were precisely those of a ventriloquist. Another asked if M. Paskos's face and lips, as he turned the instrument, did not resemble the grimaces of a ventriloquist. A third admitted that the phonograph might emit sounds, but believed it was much helped by the manipulator. Finally, the Academy requested M. du Moncel to try the experiment, and as he was not accustomed to speak into the instrument it was unsuccessful, to the great joy of the incredulous. Some members of the Academy, however, desirous of ascertaining the real nature of the effects, begged M. Paskos to repeat the experiment before them again, under such conditions as they laid down for him. M. Paskos complied with this request, and they were absolutely satisfied with the result. Others still remained incredulous, and it was necessary before they accepted the fact that speech should be reproduced in so simple a way.

The anecdote I have just related cannot be interpreted to the discredit of the Académie des Sciences, since the Academy is bound to preserve the true principles of science intact, and to accept startling facts only after careful examination. Owing to this attitude, all that emanates from the Academy can be received with complete confidence; and we cannot approve too highly of reserve which does not give way to the first impulse of enthusiasm and admiration.

Its present achievements in recording music are wonderful. The phonograph will reproduce any kind of music—singing, the piano, violin, cornet, oboe, etc.—with a beauty of tone and accuracy astonishing to the musician. It is possible also to magnify musical sounds without distorting them, as often happens where speech is concerned. Thus, when a *musicale* is arranged, the phonograph is put up so as to be heard one hundred feet away. Even should the phonograph never reach greater perfection than its present stage, which is hardly possible in this age, it is and will

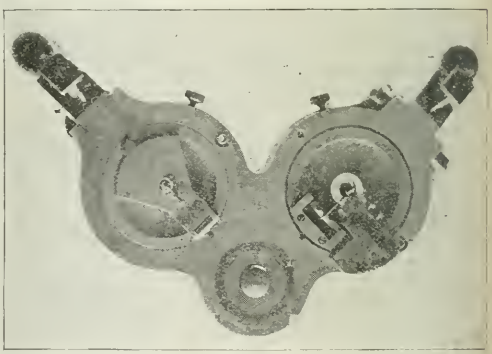

FIG. 5.

continue to be of the greatest use to musicians, elocutionists, authors, editors, and physicians. To this last-named profession, of which I am a member, I have been the means of directing their attention to the practical use of the phonograph in medicine.

For several years past I have devoted considerable time to studying the uses to which as a recorder of the sounds of disease and organs in health, upon which the physician

depends so much for the accuracy of his diagnosis. Already I can say, notwithstanding its many imperfections, the phonograph is made to record many of the characteristic sounds of disease of the respiratory apparatus. For example, when in good voice the vocal expression of singers may be recorded and kept for comparison with the sound produced in case the vocal bands are affected. Time and again have I realized great benefit from the phonograph of tenors, baritones, and bassos among my patients, and not only have thus been able to recognize the difference in shade of tone and quality, and thus direct my attention to remedying the defect, but patients have also been able to recognize the deterioration of their voices from the normal standard themselves. This is one of the reasons why I desire to forcibly place before you the possible advantage the phonograph possesses in the perfection of elocution and singing, and to laryngologists in particular.

As a specialist in the department of medicine involving diseases of the throat, nose, and chest, I owe much of what little success I have had to the phonograph. Naturally, my practice brings me into direct contact with celebrated people of high vocal culture, many with already fully trained voices, and so from the outset the phonograph which I made as standards of singing, speaking, etc., represented a condition very near the standard of perfection which both teachers of singing and elocution are striving to attain. The excellent artists whose records I have taken, and treasure very much, were those educated in singing in the various methods of the German, Italian, and French schools, and representing over and over again these phonographs, I have been able to detect readily any change or oncoming change in the normal action of the vocal bands. It is astonishing to hear the difference in the methods that the special training of one of these schools gives to singers, to actors, and elocutionists; and more astonishing it is to compare singers of a mixed school with those whose singing is simply a natural exponent of fine vocal organs plus the training. The music that is in the well-trained artist rings forth its melody in pure musical sound from out of the indented pulse-waves imprinted on the cylinder of wax. By utilizing these for a comparative study with the lesser natural and other voices, I have reached much profit in the study of the different shading of tones and quality possessed by their vocal organs.

Mr. Edison's intention is now nearly fulfilled in being able to manufacture a quantity of instruments as perfect as the best of the present experimental machines, and to make them so automatic in action and so easily adjusted that everyone who uses a sewing-machine or typewriter or a telephone, can use the phonograph; we concede at once what wonderful field is before it.

The price of phonographs is nominal, and the new wax cylinders upon them cost scarcely more than writing-paper. Once a cylinder has been engraved or has had a message recorded upon it, it can be passed through the phonograph any number of times apparently without deterioration. I possess some valuable phonograms which have been read, sung, and played thousands of times by the phonograph, and no special indication of wear is observable. Finally, bear in mind that having once obtained a good phonogram, it can be multiplied and duplicated at small cost. What a wonderful prospect opens before us. This duplication of phonograms is not known to us as yet, but no doubt experiment will give it to the public, and duplication will be as common as in photography.

Imagine what the phonograph will do for the man on the borders of civilization. It will supply him with books in a far more welcome shape than print, for phonographs will read themselves. The mail will bring him the latest play from London, or opera from Vienna. If he cares for political speeches, he can have the *Congressional Record* in the shape of phonograms. It is possible even to imagine that many books and stories may not see print at all; they will go into the hands of their readers or hearers rather as phonograms. But think what a musical critic can do for his public. He can give whole arias from an opera or entire movements from a symphony, by way of proof or illustration. The very tones of an actor's or singer's voice might be reproduced in the morning notice of last night's important dramatic or musical event.

In music, as already hinted, the value of the phonograph in its present stage is indisputable. Musicians are divided, probably always will be, as to the manner in which certain famous symphonies ought to be conducted. The metronome marks used by Beethoven are at best but uncertain guides; while no written directions as to dynamic values, expression, etc., are worth much. The phonograph will make it possible for the musician of the future to know exactly how our composers wished their music given, for it will repeat that music as played today, with every shade of expression, with all its infinite changes of time. Moreover, the phonograph offers to the composer that long-sought instrument, an automatic recorder of improvisation upon the piano or other instrument. In the far-off future, when our descendants wish to compare our simple little Wagner operas with the complex productions of their own times, requiring, perhaps, a dozen orchestras playing in half a dozen different keys at once, they will have an accurate phonographic record of our harmonic simplicity. In logic we say, that where a premise is established the deduction is evident. So what can be done in one instance can be done in all other similar instances. Those persons who smile incredulously when it is said that the perfected phonograph will do away with letter-writing, will read to us, sing to us, teach us foreign languages with their proper accents, teach us different methods of singing, elocution, give us books, music, plays, speeches, at almost no cost, become a constant source of instruction and amusement, must have forgotten the ridicule they heaped upon the rumor that an American inventor proposed to talk from New York to Chicago. The achievements of the phonograph will be no less wonderful than those of the telephone.

Marvellous as this instrument is, it is still quite new, and it is impossible to say to what degree of perfection it may yet be carried. It has already opened the door to an entirely new and untried field in the realm of sound. It is a new instrument in the hands of science, wherewith to search out laws in nature yet unknown. Already it has suggested many valuable uses. Undoubtedly it is the most remarkable invention of this century.

If time permitted I should talk more in detail regarding the use of the phonograph as a teacher of singing, elocution, etc., but from the demonstration of phonograms one must be satisfied of the truth and of the value of the phonograph.

I am still in hopes, and notwithstanding the fact that at present the microphone is very unsatisfactory in its workings in many respects, to be able to record the sounds of the heart and respiratory tract both in health and disease. The value of such record, I need not tell you, would go a great way toward the practical education of our medical students in the groundwork of physical diagnosis.

I have already made several records of pathognomonic sounds, but my work, owing to the pressure of time and the responsibilities of a large practice, is still so incomplete that I hesitate to present it to such an august body of distinguished medical men.

At the next Congress I may show you the cabinet of records, which will demonstrate aurally the sounds of disease of the air-passages and heart just as we hear them in the hospital wards, and as we recognize them from the descriptions in our books, of lessened or intensified pitch and changed quality.

In my own specialty the phonograph has been of much service. In all diseases affecting the vocal bands we are sure to have a change in the character of the

vocal sounds. These sounds in not a few instances are pathognomonic, but as one.

Experience and observation have not been extensive enough, we have as yet no accepted classification, without which phonographic records would signify little. With a competent microphone, as I hope and feel it can be perfected, both the classification and recording of these sounds will be made so that all of us, even the general practitioner, will be able to make his diagnosis more positive.

To my American colleagues, and to those of other countries who may chance to come to my city, I extend a cordial invitation to visit my workshop, which unfortunately I could not carry with me, and see the work as it has progressed up to this time.

I shall be ever ready to demonstrate and show you how far I have succeeded, and so give you the ocular proof of what I have laid claim to in this paper.

460 Lexington Avenue.

OBSERVATIONS ON PHYSIOLOGICAL PULMONARY ATELECTASIS.

Being Part of a Report of the Committee on Clinical Medicine of The Medical Society of the State of California.

By ALBERT ABRAMS, A.M., M.D., F.R.M.S., Chairman of the Committee.

San Francisco, Cal.

Professor of Pathology, Cooper Medical College; President of the San Francisco Medico-Chirurgical Society; Vice-President of the Medical Society of the State of California.

Mr. President and Fellow Members: At a previous meeting of this Society I presented a paper on "Pulmonary Atelectasis as a cause of Anæmia" ("Transactions of The Medical Society of the State of California, 1892"). I will succinctly recount the essential facts of that paper.

There are present over the thorax of apparently normal individuals constant areas of diminished lung resonance, varying from dulness to flatness as obtained by percussion. These areas vary in number and situation as far as the individual case is concerned, but they admit in the aggregate of definite localization. The areas of dulness or atelectatic zones, as I will call them, are no longer demonstrable by percussion after repeated forced inspirations. The atelectatic zones are dependent on circumscribed pulmonary atelectasis, or collapse of limited portions of the lung. I have referred to this form of atelectasis as physiological, with the object of employing the term for differentiation only. The physiological atelectasis under consideration is an eradicable condition dissociated with any demonstrable lesion. When the atelectatic zones are multiplied or augmented in area, especially in young people, they are associated with the symptomatic complex of anæmia, and finally, when the atelectatic zones are dispelled by respiratory gymnastics, the syndrome of anæmia disappears, while its recrudescence is always associated with a reappearance of the atelectatic zones.

My observations have been extended since the publication of my original paper, and the results attained confirm my primary conclusions. While it is true, from the stand-point of the physiologist, that the lungs during life are in a stretched condition, it is equally true, from the stand-point of the clinician, that certain portions of the lung are collapsed and deprived of sufficient air to yield a dulness, or in some instances a flatness, on percussion. These areas of dulness vary, as determined by linear percussion, from a twenty-five cent piece to a dollar in size, or even more.

The atelectatic zones are only permanently absent when the lungs are emphysematous, and temporarily so after repeated deep inspirations. I have noted in my investigations that after forced inspirations are made the atelectatic zones, in adults as well as in children, can be dispelled, reappearing in a few minutes when tranquil breathing is resumed, and continuing so until an increased demand is again made on the capacity of the lungs.

The facts just enunciated do not refer to the areas of lung tissue intermediary to the atelectatic zones, for we already know from the observations of others, especially Da Costa, that when percussion is made over the lungs by respiratory percussion, as it is called, at the end of full inspiration, a sound of higher pitch and vesiculotympanitic quality is obtained; whereas a held expiration diminishes the resonance.

In the accompanying illustrations (Figs. 1 and 2) I have projected a composite picture defining the situation

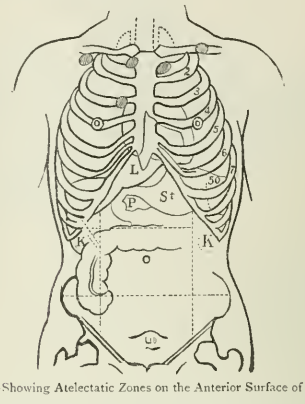

Fig. 1.—Showing Atelectatic Zones on the Anterior Surface of the Chest.

of the atelectatic zones, based on examination of over one hundred apparently healthy individuals, children as well as adults.

It may be remarked that the atelectatic zones on the posterior surface of the chest-wall are more frequent, and admit of more definite localization, than those on the anterior surface of the thoracic wall.

The atelectatic zones, as shown in the illustrations, do not represent the only areas of lung tissue that are normally incapacitated, for aside from the fact that collapsed lung remote from the chest-wall will elude percussion, there are other superficial areas of too limited an extent to yield a dulness on percussion. The practical conclu-

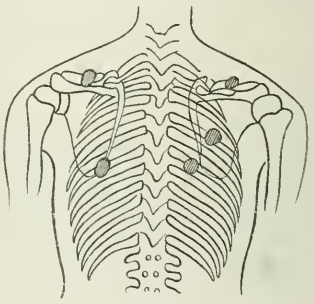

Fig. 2.—Showing Atelectatic Zones on the Posterior Surface of the Chest.

sions that can be formulated as a result of these observations may be summarized under the following groupings:

1. The relation that pulmonary atelectasis bears to anæmia.

2. The mistakes that may accrue from misinterpretation of the physical signs in the examination of the chest, and the correction of the conventional errors of topographical percussion.

3. The relation that pulmonary atelectasis bears to tuberculosis.

4. The aid afforded to auscultation by the elimination of atelectasis.

1. I have already shown in my previous paper that

anæmia of pulmonary origin exists, and furthermore, that this anæmia is associated with extensive areas of lung dulness. That when this latter is corrected, amelioration and recovery from the anæmia occur. I have also referred in my original paper to the fact that increased respiratory activity is of great therapeutic value in anæmia from any cause.

2. The mistakes that may accrue from misinterpretation of the physical signs of atelectatic dulness, from dulness caused by lung consolidation, are many, and in consequence of mistakes occurring in my own practice and in the practice of other physicians, I invariably adopt the expedient of having the patient practise forced breathing before making an examination of the chest.

If inflation of the lung cannot be secured with the patient in the erect posture, I place him in the right or left lateral posture, according to whether an examination of the left or right lung is desired.

I have often found that dulness produced by lung consolidation will frequently disappear, to be supplanted by resonance after forced deep breathing.

This fact may, to the novitiate in physical diagnosis, be mistaken for atelectatic dulness. Taken altogether, percussion of the lungs is an untrustworthy method of diagnosis unless it is controlled by auscultation. I hold that topographical percussion, as obtained ordinarily, is of inconstant value. The limitation of organs by percussion, especially of the heart, will vary from day to day, and the percussional area of dulness in the same case, and at the same time, will be variously obtained by different diagnosticians. The borders of the heart, liver, and spleen are dependent on the degree of lung inflation, and must vary according to the activity of respiration.

Topographical percussion must always be based upon the state of pulmonary inflation, and the results governed accordingly.

3. The relation that atelectasis bears to pulmonary tuberculosis is an important one. A properly inflated lung affords adequate protection against pulmonary tuberculosis. A collapsed area of lung affords a nidus for the specific microbes. The facultative anærobins thrive best in an illy-ventilated lung. The foregoing statements are borne out by theory and statistical evidence.

Pulmonary tuberculosis is frequently initiated by the symptomatic picture of anæmia. This anæmia is unquestionably of pulmonary origin, and is associated with demonstrable atelectatic zones.

The atelectatic zones correspond with the destructive routes followed by incipient pulmonary tuberculosis.

4. The aid afforded auscultation by elimination of atelectasis is obvious. Auscultation of the lungs should always be conducted with the patient in different postures, the object being to utilize the actual respiratory capacity of the lungs, thus eliminating the auscultatory phenomena of atelectasis and accentuating abnormal sounds which may be present.

I have recourse to the following manœuvre for eliciting pleural friction-sounds when absent, and accentuating them when present, by having the patient lie on the suspected side or region for half a minute or longer, after having taken a deep inspiration. This position favors the approximation of the two pleural layers.

Now, when the patient adopts the sitting posture and attempts forced expiration, a friction-sound is heard which is usually intensified during the subsequent inspiration.

Unless a deep inspiration is taken before the patient lies on the suspected side, crepitant râles, concomitants of atelectasis, will be heard. I consider the foregoing manœuvre of more value for diagnosis than any of the methods usually described for eliciting and differentiating the same phenomena.

Low Temperature.—Dr. George R. Dean, writing in the *Medical and Surgical Reporter* of June 30, 1894, relates a case of cystitis in which the temperature fell on several occasions to 92° F.

A CASE OF LYMPHADENOMA (HODGKIN'S DISEASE) ACCOMPANIED BY FEATURES CHARACTERISTIC OF MYXŒDEMA, AND OTHERS SUGGESTIVE OF ACROMEGALY.

By W. A. CROSS, M.D.,

JENKINTON, PA.

I DESIRE to put the following case on record on account of its unusual complications, and the manner of their development.

Mrs. H——, aged thirty-four, American. A person of more than ordinary intelligence, of good family history, and in the enjoyment of exceptionally good health until the commencement of her last illness. She was a happy wife and mother. Menstruation appeared at fourteen years, and was always normally performed. She gave birth to five children, two boys and three girls, and had no miscarriages. There was no inherited predisposition to glandular troubles.

In July, 1892, there developed a very troublesome cough of a spasmodic character; the paroxysms occurred both day and night, and greatly interfered with her sleep and rest. I could not discover any lesion which would account for its origin and persistency. I made use of all sorts of means for its relief, with very poor success. Antispasmodics made some impression, but the best results were obtained from the administration of an emulsion of cod-liver oil; this gave her considerable relief for a time.

Her good constitution enabled her to resist the evil effects of these frequent paroxysms, with the attendant loss of sleep and rest, for a long while. She remained under my care for one year, and then, as I had failed to afford her any adequate relief, and had not discovered the nature of her disease, she proposed putting herself under the observation of some other physician.

In July, 1893, she consulted Dr. Louis Jurist, of Philadelphia. By this time her general health had begun to fail; she had a cachectic appearance suggestive of tuberculosis, or some malignant disease. I knew Dr. Jurist to be a careful observer, and trusted that he might be more successful than I in getting at the cause of her trouble, and waited patiently for his judgment of the case.

I did not see the patient again for a period of six weeks, and then, while visiting another member of the family I had the opportunity of observing her carefully. She still had her cough, had lost much flesh, and was very anæmic. My attention was called to a swelling on the right side of the sternum, high up. I believed this to be connected with her disease in some way, but I did not imagine its significance at that time.

The next time I saw the patient was October 22, 1893. By this time her condition was such that she could not visit Dr. Jurist at his office in the city, and, at his request, I took charge of her at her home.

I do not know when the myxœdematous features first became apparent, but when I saw her at this time my attention was attracted to them immediately. Her physician did not write me fully in regard to the sequence of development of the various features, but said "Mrs. H——'s case interests me very much, and I am obliged to you for your willingness to study it with me. Many things have passed through my mind regarding her condition: tubercle, myxœdema, acromegaly, and malignant disease have all had fair consideration. I do not quite understand the bony protrusion on the right of her sternum. Is the growth in her neck secondary? Her wasting would indicate a serious encroachment on her vitality. Might she not have a mediastinal tumor? I would gladly hear from you."

My examination of the patient at this time discovered the following conditions: She presented many of the characteristic features of myxœdema. The physiognomy was dull and mask like, but not to an exaggerated degree; the face was not enlarged to the extent that is usual in these cases; the skin was dry and of a peculiar yellow-

ish white color; both upper and lower eyelids were swollen, with a puffiness of the tissues below the lower lids; the nose was thin, having a pinched appearance; the mouth was natural, excepting the deep lines on either side of it; the pendulous lower lip was absent; the tongue was a little thickened; there was a slight hesitancy in her speech, and articulation was not perfectly distinct; the scalp was dry, the hair scanty, dry, and brittle; the hair which is usually found on the forearms and legs had disappeared, also that in the axilla and about the pubes; the forearms were enlarged and thickened, particularly at the wrists, indicating an enlargement of the bony tissues; the hands were large and puffy, with a remarkable clubbing of the finger-tips; the finger-nails were thickened and curved to an unusual degree; the hands and fingers were so swollen that they were clumsy, and the patient could not make use of either needle or pen; the legs and feet showed the same abnormal features as were present in the upper extremities. A prominent peculiarity of the foot was the projection of the calcaneum and a welt of hard tissue along the outer aspect of the foot.

There was an enlarged gland about the size of a hen's egg on the left side of the neck, just above the clavicle, and posterior to the sterno-mastoid muscle. The mind was clear, memory apparently unimpaired. She conversed intelligently, had poor appetite, digestion was not good, the bowels moved twice daily, the kidneys acted all right. She would have slept well if it had not been for the cough; vision was normal; had no pain; felt weak; heart's action was rapid and impaired; complained of shortness of breath. There was some difficulty in swallowing. The temperature ranged from 98° F. in the morning to 99° F. in the evening; pulse, 105 in the morning; 120 in the evening. Complained of not feeling warm; there was no perspiration. Passed forty-six ounces of urine in twenty-four hours, of low specific gravity, containing no albumin, no casts, no sugar, phosphates in abundance, urates below normal; reaction acid; menstruation normal.

The patient, although weak, was up and about, overseeing her household affairs; locomotion was impaired, and she tired easily, but she still possessed a considerable amount of will-power.

A powdered extract of thyroid gland was administered three times per day for about four weeks, with apparently no improvement; the raw glands finely minced and taken with her other food, were tried for a while, but these were so distasteful to her that their use was soon discontinued.

From the last week in November to the middle of December no active treatment was employed; during this period she grew rapidly worse, the myxœdematous features became more pronounced, the cough was persistent, there was no desire for food, and there was a scanty secretion of urine; for a number of days she did not pass more than one pint in twenty-four hours. The lower limbs became œdematous, she was dull looking and acting, slept the most of her time day and night. The sleep was a restless one, disturbed not only by the cough, but by ugly dreams which really amounted to hallucinations. She could not lie down, neither could she lean back in her chair, owing to the dyspnœa occasioned by such positions. The only way in which she could get rest was by sitting in her chair, leaning forward with her head resting upon a pillow placed upon a table in front of her. In such a posture she sat and slept the most of her time. Lymphoid tumors developed on the right side of the neck, and in the right axilla. Menstruation was missed for the first time in November, and did not occur again.

Dr. J. C. Wilson, of Philadelphia, saw the patient, in consultation, November 22, 1893. His diagnosis was lymphadenoma accompanied by features suggestive of both myxœdema and acromegaly. He advised the use of the thyroid extract, and also Fowler's solution to the point of toleration.

A thyroid extract prepared by Dr. George W. Crary, of New York City, was obtained. As an initial dose we gave two drops three times per day, this was gradually increased until we reached eight drops t.i.d.; at this point the dyspnœa and disturbed heart's action became so great that it was necessary to discontinue its use for a couple of days. We resumed with a two-drop dose, and added a drop to the dose each day, until fifteen drops t.i.d. were taken, without any inconvenience whatever.

As we advanced the second time, her condition improved rapidly; her paroxysms of coughing became less frequent and distressing. She did not sleep so much through the day, and her rest was less disturbed at night. She could lean back in her chair, and could lie down in bed. The appetite improved. She could swallow solids without difficulty, and any reasonable article of food could be taken without discomfort.

I must not neglect to state that the arsenic occasioned so much gastric distress that we were obliged to discontinue its use; the appetite did not improve until after the arsenic was dropped.

The quantity of urine secreted steadily increased until it reached seventy-two ounces daily; it was analyzed frequently, the urates remained a little below normal in quantity, phosphates in abundance, no albumin, no casts, no sugar, specific gravity 1.020 to 1.025.

After the thyroid extract had been used for about three weeks the swellings in the various parts of the body showed signs of decrease. The face was the first to lose its puffiness. The enlargement of the right forearm, wrist, and hand became reduced in size. One week later the same process took place in the left upper extremity, next followed the right, and then the left lower extremity.

As the œdema decreased the skin lost its glazed appearance and commenced scaling, the new skin was soft, and was often moist with perspiration; a new hairy growth appeared upon the arms, legs, and head. The clubbed condition of the fingers was less apparent, and she was able to use her needle once more.

That which interested and astonished me most was the attempt to correct the exaggerated curve of the finger-nails; they rapidly changed their shape, and two of them on the right hand became almost normal in appearance.

The œdema of the legs and feet became so much reduced that the patient was able once more to wear her shoes, to walk about her room, then to go up and down stairs, to walk out upon the piazza, and finally to take a sleigh-ride.

The glandular trouble did not improve, but went from bad to worse. About the middle of February a retrograde change commenced, the cough became more annoying, the heart's action more feeble, the appetite failed. Swallowing became a distressing act, soft food could be gotten down fairly well, but the attempt to swallow liquids occasioned a paroxysm of coughing and strangling which was painful to witness; the taking of a meal was dreaded, and consumed a great deal of time. Liquids were taken through a tube, and by certain manœuvring were finally swallowed. A stomach-tube was passed without much difficulty, but the patient preferred not to use it, and persisted in her own way of getting food and drink down her œsophagus.

The weakened action of the heart and the accompanying dyspnœa necessitated the withdrawal of the thyroid extract for a few days. As no relief was experienced from its discontinuance we again resumed its administration, but it had no further control—the œdema, dyspnœa, dysphagia, drowsiness, hallucinations, and bodily weakness increased steadily, and she died March 15, 1894.

Dr. Jurist continued to see the case at intervals during her illness, and Dr. Wharton Sinkler, of Philadelphia, saw her in consultation a few days before her death.

Dr. Boyer, of Philadelphia, made an examination of the blood; the result was very interesting. There were

five million eight hundred thousand red corpuscles to the cubic millimetre, and forty eight thousand white corpuscles to the cubic millimetre, or a proportion of about one white to one hundred and twenty red. The percentage of hæmoglobin was about sixty.

It is greatly to be regretted that a post mortem could not be had; it would have been exceedingly interesting, and would most likely have thrown some light on the pathology of the disease. It would have indicated the condition of the spleen and internal lymphatics, and would have determined whether there was present a mediastinal tumor, and would also have shown the condition of the bronchial glands.

In summing up the case, we notice first the persistent spasmodic cough. This cough was evidently dependent upon either the pressure of a mediastinal tumor or enlarged bronchial glands, perhaps both. The probability of the existence of a mediastinal growth early in the trouble is enhanced by the development of the embarrassed breathing and difficult deglutition among the first features in the disease.

The cough had existed for very nearly a year before the patient showed signs of cachexia. During this period she was to all outward appearances well. She attended to her household and social duties, was cheerful, had a good appetite the most of the time, the bowels moved regularly, and she menstruated normally.

We have next the increasing signs of cachexia, which for a long time could not be accounted for. Then came the tumor on the right side of the sternum, followed soon by the enlarged gland on the left side of the neck, and the apparent disappearance of the thyroid gland.

With these changes came the development of the characteristic features of myxœdema—the multiplication of the lymphoid growths in different parts of the body. We have the remarkable clubbing of the finger-tips, the curve of the finger- and toe-nails, the apparent projection of the calcaneum, and the welt along the outer edge of the feet, suggestive of acromegaly.

The effect of the thyroid extract upon the myxœdematous features was for a time most remarkable, followed in a short while by its failure of control, with increasing weakness, stupidity, hallucinations, dyspnœa, cardiac palpitation, suffocation, and death.

Drs. J. C. Wilson and Wharton Sinkler concur in the opinion that the case was originally one of Hodgkin's disease, and that the myxœdema occurred symptomatically, as a result of involvement of the thyroid gland due to the lymphadenoma.

I am inclined to the belief that there existed a mediastinal tumor, as was insisted on by Dr. Jurist, and that this growth was directly or indirectly the cause of the cough and of the dyspnœa. Why the paroxysms of coughing should have become less frequent and severe, and the ability to swallow should have improved under the use of the extract, I am unable to understand.

The case, from any stand-point, was an exceedingly interesting one, and worthy of putting on record.

Seventeen-Year Locusts.—The newspapers have reported several cases of death following bites from these insects.

A New Location for the Soul.—The champion title of the year must surely be "A New Systematic Treatment of All Diseased Conditions, from Strict Electrical Polarization, Adapted Particularly for Examinations and the Treatment of Disease. Embracing Some Entirely New Principles Concerning Portions of Our Organism. Also, An Entirely New Motive Power Regarding the Cleansing and Circulation of the Blood by Strict Electrical Polarization, Locating Exactly the Seat or Throne of that Eternal, Immortal, and Ever-Controlling Principle Denominated the Soul or Mind, Together with Very Many Other New and Important Facts and Principles. By A. H. Stevens, M.D., E.D." Dr. Stevens locates the Soul in the corpus callosum.

Where Our Drugs Come From.—"Principal Exports to the United States" is the title of a pamphlet lately issued by the State Department, which is of especial interest from the fact that it gives the value of our imports, and the names of the products, and the countries from which they are derived. The report is compiled from the reports of the various consuls of this country, and the figures bearing upon the extent of the drug and chemical imports are interesting both on account of the magnitude of the commercial interests involved in the trade, and the fact that they show that the most remote portions of the earth are called upon to supply our demand for drugs and medicines. The figures given, with a few exceptions, cover the calendar year 1892, and the report is arranged to show the value of goods as "declared for export" in the various consular districts. From the Buda Pesth and Vienna districts of Austria-Hungary we receive drugs and chemicals amounting to $122,758. From Trieste insect powder and flowers amounting to $71,884. From France our imports included olive oil, drugs, chemicals, argols, dyestuffs, toilet articles, and perfumery, and amounted to $2,564,000. Germany furnished us with drugs, chemicals, dyes, colors, and essential oils to the amount of $9,193,849. Greece sent us $24,108 worth of sponges. From Italy we received olive oil, brimstone, canary seed, crude glycerine, soap, argols, orris root, almonds, licorice, sumac, and essential oils, valued at $4 909,704. The Netherlands sent us cacao butter, drugs, and dyestuffs amounting to $366,470. Corkwood worth $1,069,057, and argols worth $131,805, came from Portugal. The Batoum district, Russia, furnished us licorice root valued at $624,363. Spain furnished us cream of tartar, glycerine, licorice, saffron, corkwood, olive oil, and canary seed worth $1,505,505. Sweden and Norway sent us $82,055 worth of cod-liver oil and oxalic acid worth $18,090. Little Switzerland sent us anilines, dyestuffs, and chemicals worth $439,518, and enough argols and beef extract to make the total $475,760. We received from Turkey, in Europe, $403,013; attar of roses, $141,929; gum tragacanth, $55,620. From the United Kingdom, which seems to be a sort of clearing-house for the world, we received drugs and chemicals amounting to $12,570,180. British North America sent us $22,003 worth of senega root and $12,664 worth of sulphur. Sarsaparilla worth $67,577; vanilla, $710,580; fustic, $130,913; gum chicle, $475,665, and silver dollars, which are apparently a drug on the market, to the amount of $454,031, came to us from Mexico. China furnished cassia, $164,497; gall nuts, $5,730, and rhubarb, $16,454. Dutch India, gum damar, $64.729; gum copal, $30,452; cassia, $26,593. Japan, sulphur, $226,025; menthol, $23 391; camphor, $522,152. Philippine Islands, indigo, $16.369; ylang ylang oil, $10,002. Turkey, in Asia, licorice root, $1,023,710; opium, $451,431. New Zealand, kauri gum, $1,997,607. Tahiti (Society Is'ands), vanilla, $36,698. Honduras, sarsaparilla, $30,951; chicle, $4,604. Brazil, copaiba, $28,958; guarana, $8,078; castor beans, $22,774. Chili, nitrate of soda, $2,880,643; iodine, $579,313. Peru, coca leaves and elixir, $5,329. British West Indies, sponges, $236,555; dyewoods. $186,842; ginger, $40,734; pimento, $126,400. Dutch West Indies (Curaçao), aloes, $3,047. Guadeloupe, vanilla, $1,660. San Domingo, dyewoods, $38,307. Porto Rico, bay rum and oil, $3,494. Canary Islands, cochineal, $17,382; almonds, $3,877. British Africa, argols, $10,088; palm oil, $1,892. Egypt, senna, $36,627. Algiers, corkwood, $22,159. Morocco, canary, cumin, and coriander seeds, $4,735. Zanzibar, cloves, $289,688; clove stems, $4,058; gum copal, $51,836. British Asia, Aden, civet, $4,898. Calcutta, drugs, $4,272,076; saltpetre, $518,845. Ceylon, cocoanut oil, $937,331; cinchona, $73,185; essential oils, $73,015. Hong Kong, opium, prepared, $543,091; cassia, $79,170; medicines, $51,418. Singapore, gambier, $733,855; gum copal, $119,493.—*Pharmaceutical Era.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, September 1, 1894.

THE CONFIDENTIAL RELATIONS OF THE PHYSICIAN.

THE recent decision of Judge Cole, of the Supreme Court of the District of Columbia, holding that physicians and lawyers are not exempted from giving testimony when called upon in court, on the ground that such information was professionally confidential, will strike everyone who learns of it with becoming surprise. The ruling, wise as it may appear to the learned judge, will be viewed by the community at large in a widely different light. Were it not that this opinion has been deliberately rendered in a high court of justice by one of its officers, it might be looked upon as an attempt to create a cheap sensation, or a foolish bid for personal notoriety. Fortunately, however, its very absurdity is its death blow. Physicians have heretofore gone to prison rather than abuse their patients' confidences, and they will do so again when opportunities force them to such extremities, in spite of judges' edicts or juries' findings The opinion of the learned judge is contrary to that of all wise and good men since civilization began or social relations were in any way respected. It has been the bulwark of the Hippocratic oath, the fundamental principle of legal pleading, and the corner-stone of the Christian religion, to respect and hold sacred the privileged communications of such as come to their confessors for sympathy, forgiveness, and help. The very stability of society, the preservation of social relations, the maintenance of honorable intercourse, the most sacred obligations existing between members of the human family, rest upon the uncompromising integrity of those principles which even in heathen ages have made us trust one another. And yet for the sake of obtaining some evidence in a divorce suit an expounder of the law makes bold to insult the higher instincts of our humanity by aiming a blow at the honor of every man who hears a confession. If we mistake not, the learned judge will stand alone in his opinion, which is in itself a distinction sufficiently gratifying to him, perhaps, as opposed to that of the rest of mankind, and is worthy of remark on that account. It is difficult to imagine the great harm that would ensue if the professions of law and medicine, forgetting all their time-honored customs, their treasured traditions, and their sacred rights, should be compelled to abide by the absurd, illogical, and damaging decision of our learned interpreter of legal obligations. Let any practitioner of medicine think for himself of the disastrous consequences which would result from the disclosure in court of those family secrets which he has been forced to know, even within the circle of his own practice. And how much more for the profession at large!

Fortunately, however, the remarkable ruling will not affect any medical or legal gentleman outside the jurisdiction of the court in question, and will doubtless be very properly overruled in the next test-case. In any event, with the medical profession the opinion will always be, as it has always been, that no physician or surgeon must, directly or indirectly, under any circumstances or conditions, at no time or place, abuse the confidence of anyone who has trusted to his personal honor in the dire extremities of sickness and suffering. The man who would do otherwise, judge or no judge, would disgrace his calling, would prostitute the highest obligation of his profession, and outrage the most sacred trust that could be imposed.

THE DANGER OF THE COMMUNION CUP.

WE are pleased to know that the frequent discussion in these columns as to the danger of the communion cup in propagating disease is bearing fruit by transference to the columns of the daily press. The public is thus being educated to the necessities of the situation, and there is a reasonable hope that the claims of preventive medicine will be vindicated even against those whose faith in old forms have failed to listen to reason before.

The following telling experience, detailed by Dr. Albert S. Ashmead in a recent letter to the *Sun*, points its own moral:

"The last time I knelt at the communion altar of the Episcopal Church there knelt at one side of me a patient whom I knew, as I was treating him at the time, to be a syphilitic; his mouth had mucous patches, which make the disease especially contagious. This person took the cup before it came to me. Of course, I let the cup pass.

"At another time the person next to me, but following me in the use of the cup, was also a patient of mine, in an advanced stage of tuberculosis. The mouth of this person was in a condition dangerous to his neighbor.

"Of course, no man who is not a complete survival of the Middle Ages can assert that, under these circumstances, a man (if he knew) should apply his lips to a probably dangerously contaminated cup, trusting in the protection of the Lord, who has allowed hundreds, a hundred times, to perish in burning or earth shaken churches, while they were in the very act of worshipping Him."

Verily a little sermon in itself, and from a churchman and a physician, who views both sides reverently for Christianity's sake, and candidly for the vindication of truth.

The *Sun*, with its usual vigor of diction and directness of aim, thus valiantly takes sides with science and fact as against tradition and prejudice:

"When a physician writes to a newspaper, as one wrote to the *Sun* the other day, that he refrained from drinking from the chalice at a recent celebration of the Eucharist in the Episcopal Church, because before him two patients of his had sipped from the cup, the one afflicted with an odious and the other with a destructive

communicable disease, reasonable fears of the danger of the hallowed practice are excited even among the most devout of communicants; and such fears, thus justified, are quickly and widely diffused. Is it unlikely, then, is it not probable, that this alarm will become so extensive and so great that all churches whose doctrines require that both elements shall be administered to the whole body of communicants will be compelled to imitate the Rochester example, or adopt some other method devised for the same purpose, in order to save the communion in both kinds from perilous disease?"

The fact of danger is indisputable, and the conclusion for safety is irresistible. We are confident that it is only a question of time when, as the *Sun* says, all churches will be compelled to imitate the Rochester example. Contagion is no respecter of cups, men, or place, when the essential conditions of its propagation are present. The Christian will never yield up the cup; why should he object to its being clean and free from danger? Why one contaminated chalice against many safe ones?

OPHTHALMIC HEMICRANIA.

Under this title in *Il Raccoglitore medico*, January 10, 1894, Dr. Palombi gives an interesting account of hereditary ophthalmic hemicrania, together with a consideration of the subject at large. The patient whose case is cited belonged to a neuropathic family, his particular trouble originating with the great grandfather and being regularly transmitted for three generations, only one person in the entire family escaping. From his earliest recollection, the patient had suffered from migraine; but like his own father and grandfather, the intensity of the trouble reached its maximum between the ages of fifteen and thirty. The author very justly criticises the term ophthalmic migraine, or hemicrania, to describe an idiopathic affection in which ocular phenomena are contingents, like the agraphia, aphasia, paresis, etc., that sometimes accompany it. The chief phenomenon is the one sided headache. The work of Galezowski and of Charcot is passed in brief review, the history of the particular case in this migrainous family seeming to challenge a little the views held by these two observers: viz, that hemicrania is allied to epilepsy, and is an affection with an anatomical substratum of chronic progressive basilar meningitis, with secondary neuritis resulting from compression. Errors have been made in regard to migraine by confounding it with the various pathological states with which it may be associated. It is a protopathic affection that may develop in persons otherwise healthy. In the case cited there had never been any premonitory symptoms.

The author notes two periods in hemicrania: the period of invasion, and the period during which appear, but not always, the following symptoms, enumerated in their order of frequency: lateral or horizontal hemianopsia, scintillating scotomata, migrainous amaurosis, amblyopia, tingling and paretic aching, aphasia, and agraphia. In the same proportion that ocular phenomena disappear, just as a curtain on the stage is drawn apart laterally, tingling and heaviness begin in the fingers, the forearm, the arm, and one-half of the face. These last-named symptoms are usually confined to one upper extremity, but the hemianopsia and scotomata are ordinarily symmetrical. When the tingling begins, the various painful symptoms disappear, and then, if present at all, different forms of aphasia come on, of which the rarest are agraphia and word-blindness. The symptoms of the first period succeed each other singly. This is their special characteristic. After a few moments of apathetic repose, the second period is ushered in by its unique symptom, headache. This pain has a special quality of its own, and can never be confounded by the patient with any other. It is indescribable. Its intensity is in proportion to those of the other symptoms and to the duration of the attack. Cerebral impotence is absolute while it lasts. The periodicity varies. Palombi admits but one cause for hemicrania: heredity. Exciting causes are numerous, of which the principal are atmospheric pressure, cold, constipation, and glaring light. Often the exciting cause is apparently wanting, and the attacks appear spontaneously.

Hemicrania, or migraine, is a vaso motor neurosis. Hypothetically, it is possible to admit a capillary apoplexy as the anatomical basis of the disorder. As preventive measures, the Italian observer finds quinine and bromides of value; and advises antifebrin during the attacks. To sum up: Hemicrania is a distinct neurosis, of which the pathogenesis and anatomical seat are unknown; it has characteristic clinical features that establish its identity, and it is analogous to hysteria and epilepsy, though it presents no traits in common with them other than heredity.

Concerning remedies, Hirt speaks of citrate of caffeine, two grains three times a day, for those cases in which the conditions of the circulation (increased tension, vasodilatation) give no suggestion. Efforts must be directed toward building up the general health by cold-water treatment, general faradization according to Beard and Rockwell's method, franklinization with the Holtz machine, and systematic gymnastic exercise at home. Sometimes lasting advantage has been obtained by change of climate, travelling, and by a stay at the mountains or seaside. Gray recommends twenty or thirty grains of bromide during the attack, and cannabis indica at other times. For anæmia, peptonate of iron in three grain doses, three times daily, is to be given when the condition is not specially marked; when pronounced general physical depression exists, quinine is to be added. In some cases of anæmia in which there are hepatic symptoms a sixtieth to a thirty-second of a grain of bichloride three times a day should be added to the iron, or the iron and quinine. Dana considers bromide of potassium, nitro-glycerin, cannabis indica, and arsenic the best remedies for continued internal use. Cannabis indica, either with or without arsenic, is the most trustworthy, and the bromides the least to be depended upon. To relieve the attacks, salicylate of soda, caffeine, antipyrine, powdered guarana, menthol, muriate of ammonia, and bromide of potassium are reliable remedies for a time, but lose their effect as do almost all other drugs. Rest is the most important element in the management of an attack, rest and perfect seclusion from the world and affairs.

Naming Streets after Medical Men.—The Parisian Municipal Council has named three streets in that city after Charcot, Trélat, and Trousseau.

News of the Week.

French Association for the Advancement of Science.—The twenty-third annual meeting of this association was held at Caen during the week commencing August 9th, under the presidency of Professor Mascart. Among the papers read in the Section of Natural and Medical Sciences was a report by Dr. Le Genole "On the Dangers of Athletic Sports in the Case of Children." Dr. F. Regnault contributed a paper "On the Causes of the Attitude Assumed by Women during Parturition;" Dr. Cartaz one "On a Special Variety of Stenosis of the Œsophagus;" Dr. Galliard one "On the Treatment of Certain Non-syphilitic Headaches by Calomel;" and Dr. Raphael Dubois one "On the Mechanism of Sleep."

Professor Billroth's Widow has been granted a yearly pension of 2,000 florins. The law allows a pension of 600 florins only to the widows of professors, and the grant of a larger sum is a mark of especial favor from the Emperor of Austria.

The British Medical Association will hold its next annual meeting in London. Dr. J. Russell Reynolds is the President-elect, and Sir William Priestly will be Chairman of the Reception Committee. The last meeting of the Association in London was in 1873, under the presidency of Sir William Fergusson.

The Tailors of Gratz not long since presented a petition to the Rector Magnificus of the University, praying that in future no student receive his doctorate diploma until he has furnished proof that he owes his tailor nothing.

The Shah of Persia, who sent for Dr. Galezowski, of Paris, to examine his eyes, has been found to have no organic disease. His general health was poor and the ocular trouble was purely functional.

The German Public Health Association will hold its nineteenth annual meeting in Magdeburg, on September 19–22, 1894. The managers of the Association have been subjected to some adverse criticism for calling a meeting so soon after the International Congress of Hygiene and Demography in Buda-Pesth, especially as many of the subjects to be discussed are the same as those to come before the congress.

Dr. Daniel Cornelius Danielssen died recently at Bergen, Norway, at the age of seventy-nine years. He was well known as an authority on leprosy, to the study of which disease he had devoted his entire life. The work which gained for him his reputation was written conjointly with W. Boeck, and contained the result of an investigation undertaken at the instance of the Norwegian Government. It was published in 1847. It was those observers who established the identity of leprosy, as seen in Norway, with elephantiasis Græcorum. Dr. Danielssen was born in Christiania, and at the time of his death was physician in-chief to the Leper Hospital in Bergen.

Dr. Philip Lonsdale died in Cos Cob, Conn., on August 21st, at the age of seventy-seven years. Dr. Lonsdale entered the United States Navy about fifty years ago, and served as surgeon on Admiral Farragut's flagship Hartford, during the civil war. He was medical director in the navy at the time of his retirement, which took place several years ago.

The American Association for the Advancement of Science will hold its next annual meeting in San Francisco. The officers for the coming year are: *President*, E. W. Morley, of Cleveland, O.; *Secretary*, F. W. Putnam, of Cambridge, Mass.; *General Secretary*, James Lewis Howe, of Louisville, Ky; *Secretary of the Council*, Charles R. Barnes, of Morrison, Wis. The vice-presidents are the chairmen of the various sections.

Typhoid Fever in Montclair.—It has been ascertained that the cause of the recent epidemic of typhoid fever in Montclair, N. J., was due to contaminated wells. Four wells, the water of which was examined and found to contain typhoid bacilli, have been ordered to be closed. The wells are all on Bloomfield Avenue, in the most thickly populated part of the town, and the pumps are of easy access to the public.

The Anatomical Congress will hold its next meeting at Basel, Switzerland, on April, 17, 18, and 19, 1895.

The Bottling of Mineral Waters in France.—The question of the artificial aëration of natural mineral waters was recently up for discussion before the Paris Academy of Medicine. The methods of bottling in use at certain springs were condemned, and the Government was urged to adopt the following precautionary regulations: 1. The sale of mineral waters which have been decanted, or artificially rendered gaseous, shall be prohibited. 2. Every application to the ministry for authorization must be accompanied by the certificate of a competent official that the water has not thus been already manipulated, and by the written promise of the proprietor not to resort to these processes. 3. Reservoirs must be hermetically closed, and should be emptied at least every twenty-four hours. They are to be so placed that the spring flows direct into the reservoir. 4. Bottles must be thoroughly sterilized before being filled, and all causes of pollution during bottling are to be most carefully avoided.

The Prize of the Accademia dei Lincei.—The royal prize of one thousand lire has been divided equally between Professors Tizzoni and Luciani for meritorious work in the fields of pathology and experimental physiology.

The Origin of Typhoid Fever.—Dr. Kenwood read a paper before the Section on Public Health at the Bristol meeting of the British Medical Association, in which he advanced the opinion that typhoid fever might be developed from simple diarrhœa, the specific bacillus springing by a process of evolution from the bacterium coli commune. He believed that dogs might be carriers of the disease, and cited four cases in support of this view. In one case an examination of the stools passed by a dog, prior and subsequent to the appearance of typhoid fever in a household in which there was no other discoverable cause, revealed the presence of typhoid germs.

Science Ignored.—"Whatever water the water-works furnishes has to be taken as it is, and we must trust to God for the rest," is a pious sentiment attributed to the Director of the Department of Public Works of Pittsburgh, who is also quoted as saying: "I don't put much trust in scientists anyway. A theory is nowhere besides practice anyway." The faith, to say nothing of the grammar, of this worthy director must be of a very high

order, such as to move microbes, if not mountains; for a more efficient method of pouring the contagia of typhoid and other water-borne diseases down the throats of the Pittsburghers than that afforded by the city waterworks could hardly be imagined. This is explained very clearly by a diagram published in the August issue of the *Pittsburgh Medical Review*. The water of the Alleghany River, polluted by sewage from the Workhouse and the Alleghany City Poor Farm, and by the surface drainage of the village of Hoboken, is deflected by means of a dam directly into the intake-pipe of the Pittsburgh water-works. Comment is needless.

The Mississippi Valley Medical Association will hold its twentieth annual meeting in Hot Springs, Ark., on November 20–23, 1894. The President of the Association is Dr. Xenophon C. Scott, of Cleveland, and the Secretary, Dr. Frederick C. Woodburn, of Indianapolis.

Dr. Bernhard Grünhut, of this city, was lost at sea from the steamship Bothnia, which arrived last Sunday in Boston from Liverpool. It is not known whether he jumped or accidentally fell overboard. He was a graduate of the College of Physicians and Surgeons, but retired from practice four years ago to devote himself to the real estate business. He was forty-eight years of age.

The Antitoxin Treatment of Diphtheria.—The Board of Health of this city proposes to ask for an appropriation from the Board of Estimate and Apportionment to enable it to manufacture diphtheria antitoxin in large quantities. Dr. Biggs, the bacteriologist of the department, has recently returned from Berlin, where he went to study the method of manufacture and the results obtained by the use of this remedy. His report is very strongly in favor of the new method, and it is upon the strength of this report that the Board has determined to undertake the production of antitoxin at a cost sufficiently low to bring it within the means of poor people.

A Conflict between State and National Health Authorities.—The Surgeon-General of the Marine Hospital Service ordered that all vessels arriving in New Orleans from Central and South American ports during August and September be detained five days after inspection instead of three days, as has been the rule hitherto. The Louisiana Board of Health regarded the execution of this rule as an unnecessary obstruction to commerce, and an appeal was made to the Secretary of the Treasury to have the order rescinded. The Secretary, however, has refused to interfere.

The Cholera is believed to be decreasing in Europe. No new districts have been invaded during the past week, and the number of new cases in already infected regions is slowly diminishing. It is hoped that, with the advent of cooler weather, the danger of any further spread of the disease will be averted.

Dr. Joseph Bancroft, one of the leading physicians of Brisbane, Queensland, died in that city a few weeks ago at the age of fifty-eight. He was born in Manchester, but had practised in Brisbane for the past thirty years.

Opposition to a Health Officer.—A petition is in circulation in Brooklyn praying for the removal of the Health Commissioner of that city. The opposition to him appears to have been excited by the firm stand which he took relative to quarantine regulations and vaccination during the small-pox alarm last winter and spring.

Dr. Oliver Wendell Holmes passed his eighty-fifth birthday on Wednesday of this week at his summer home at Beverley Farms, Mass. He is in excellent health, walks a mile every pleasant morning, and takes a long drive every afternoon. In an interview in the *Boston Advertiser* the poet said, in reply to the question whether he was writing an autobiography: "I am in the habit of dictating many of my recollections, some of my thoughts and opinions to my secretary, who has in this way accumulated a considerable mass of notes. Many of these will be interesting to my family and intimates, some of them, perhaps, to a wider public if I should see fit to make use of them, or leave them to be made use of by others. It is the one thing a person long past the active period of life can do with ease and pleasure; and in the midst of much that might as well, perhaps, perish with the writer, will, not improbably, be found memoranda deserving of permanent record." Concerning his age he said that the twelfth septennial period had always seemed to him as one of the natural boundaries of life. One who has lived to complete his eighty fifth year has had his full share, even of an old man's allowance. Whatever is granted over that is a prodigal indulgence on the part of nature.

M. Paquelin's name is familiar to medical mankind in connection with his thermo-cautery: he is, perhaps, less known as the possessor of a mental heat-producing apparatus which manifests its working by an occasional outpouring of verse, glowing, as might be expected, with "words that burn." The French journals have recently published a poetic effusion of his in which the origin of percussion is told in classic style as an accidental discovery (Have not most great discoveries in medicine been more or less accidental?) of Bacchus. When Semele was dying, with the future god of wine still in her womb, Vulcan performed Cæsarean section, and delivered the child, whom he incontinently inserted into his father's thigh. Here the lusty youngster kicked about so vigorously that he gave his parent sciatica. On escaping from his prison he was naturally thirsty, and he soon began to suffer from alcoholic tremor. When sitting on his favorite seat, a wine-cask, he was constantly drumming on it with his fingers, and hammering it with his restless feet. The difference of resonance attracted his attention, and he soon learnt

> du son dit aérique
> A discerner le sens de celui dit hydrique;
> Il sut en même temps tracer sur son tonneau
> Exactement la ligne où siégeait le niveau.

Man, we gather, soon learnt by Bacchus's example to diagnose the internal condition of a wine-cask, and Hippocrates by and by bettered the instruction by determining the limits of the spleen by percussion. Is it too much to hope that M. Paquelin's centre of poetic thermogenesis may hold out till he has found a divine origin for auscultation, inspection of the tongue, and the other esoteric mysteries of the medical art?—*British Medical Journal.*

University Reforms in Italy.—The Italian Government proposes to suppress twenty-three universities in the peninsula and to convert them into preparatory schools, creating in place of them large and thoroughly well-appointed state universities in Rome, Naples, and two or three other of the larger cities.

Reviews and Notices of Books.

An American Text-Book of the Diseases of Children. Including Special Chapters on Essential Surgical Subjects: Diseases of the Eye, Ear, Nose, and Throat; Diseases of the Skin; on the Diet, Hygiene, and General Management of Children. By American Teachers. Edited by Louis Starr, M.D. Physician to the Children's Hospital and Consulting Pediatrist to the Maternity Hospital, Philadelphia. Assisted by Thompson S. Westcott, M.D., Attending Physician to the Dispensary for Diseases of Children, Hospital of the University of Pennsylvania, Philadelphia. W. B. Saunders. 1894.

This is a comprehensive treatise on a highly important branch of practical medicine. The treatment of the various subjects by the sixty-three contributors is very uneven, four minor topics being unduly expanded at the expense of more important subjects. Nevertheless the work will be found useful as one of reference for all those interested in pediatrics.

America may well be proud of her recent contributions to the better knowledge of diseases of children, and the work before us fittingly attests the growing significance attached to this branch of general medicine. The illustrations are in the main good, and will be found especially helpful by those who have not made a special study of pædology. The colored plates are, however, exceptionally poor and misleading.

Dermatologische Zeitschrift. Herausgegeben von Dr. O. Lassar; Bd. I., Heft. I. Berlin: Verlag von S. Karger. 1894.

The first number of this new and promising skin journal, contains contributions from the editor, Dr. Lassar, and such other well-known men as Saalfeld, Kromayer, Joseph, Unna, etc. The prospectus for succeeding numbers is so rich in original articles that this department will prove of much interest to dermatologists.

A number of fairly good illustrations are bound in at the end of the volume, making over 120 pages.

Zur Behandlung der Lungentuberculose mittels Koch'scher Injectionen. Von Dr. E. Thorner, Sanitätsrath in Berlin. Berlin: S. Karger. 1894.

This is a brief history and critical study of tuberculin as employed in the treatment of pulmonary tuberculosis. The author regards this substance as a valuable remedy, capable of curing the disease in its early stages, and of bringing about very marked improvement in more advanced cases. "It is," he says, "the most important remedy we have for the treatment of tuberculosis, and it is the duty of every physician, even if not to employ the remedy himself, at least to study impartially the results of its administration."

Biography of Eminent American Physicians and Surgeons. Edited by R. French Stone, M.D., author of "Elements of Modern Medicine," Surgeon-General National Guard State of Indiana, Consulting Physician to Indianapolis City Hospital, etc. Royal 8vo, pp. 751. Indianapolis: Carlan & Hollenbeck. 1894.

This work contains seven hundred and fifty double-columned pages of biography, with photo-engraved portraits of hundreds of medical men. The editor has evidently done his best to give an impartial record of the subjects treated, and due credit must be accorded him for honesty of purpose and purity of motive. It is obviously impossible to make a work of this character beyond criticism. The most difficult of all undertakings is to please every great man who may be entitled to go down in history. Hence it is generally prudent to wait until they are dead and cannot talk back. It is true the world over that "many are called but few are chosen," but the difficulty is in drawing the line between the two. The editor has succeeded fairly well in this line, although a great many of the eminent men are heard of for the first time. Some partiality is shown for immediate neighbors in Indianapolis, but this can be explained naturally by a better knowledge of their merits than those of other eminent men in larger cities. As must inevitably happen in the best regulated family, wondrous distinctions will thrust themselves upon general notice. In New York, Philadelphia, and Chicago, the selections are not such as would be made by one having a large acquaintance with medical men of reputation. Almost as a rule the best men have the shortest notices and the fewest pictures, but they have themselves to blame in not furnishing the necessary data. The accounts of distinguished deceased members of the profession are singularly good, and add important and interesting chapters to the history of medical achievements in America. The photo-engravures are not well printed, although the plates have evidently been carefully made. The book will be interesting to a wide circle of curious readers, but best of all, will furnish valuable and trustworthy data for obituary notices.

The Etiology of Osseous Deformities of the Head, Face, Jaws, and Teeth. By Eugene S. Talbot, M.D., D.D.S., Professor Dental Surgery Woman's Medical College; Lecturer on Dental Surgery and Pathology, Rush Medical College, Chicago, etc. Third Edition. 8vo, pp. 484. Chicago: The W. T. Keener Co. 1894.

The third edition of this interesting work represents a revision and enlargement of the previous ones, and is in so much an improvement of them. The new field of inquiry, as to the relation of deformities of head, face, jaws, and teeth, to those of other forms of the degenerate type, is discussed with singular clearness, with a painstaking examination of scientific data, and with the result of formulating very instructive, interesting, and valuable data for the prosecution of this important department of anthropology. It is thus shown that the variations from the normal type of cranial, facial, and maxillary developments are in keeping with those associated with asymmetry in other organs, and for the most part are dependent upon the like causes of hereditary taint, racial peculiarities, climate, and environment. The subject—from the focal point of interest, the mouth—compasses a wide range of collateral observations, proving a remarkable and instructive association of these forms of defective development with those of the brain, the nervous centres, the bones, and incidentally with the character, temperament, and hereditary proclivities of the individual. The illustrations, over four hundred in number, are mostly original and represent in an excellent and striking manner the leading types discussed. The work as a whole is carefully done, is thoroughly scientific in tone, and adds some very important and original data to the literature of an intensely interesting study.

Prompt Aid to the Injured. A Manual of Instruction designed for Military and Civil Use. By Alva H. Doty, M.D., Major and Surgeon of Ninth Regiment, N.G.S.N.Y. Second Edition. 12mo, pp. 304. New York: D. Appleton & Co. 1894.

The second edition of this useful manual has been enlarged by a practical chapter on hygiene, and the addition of the recently adopted drill regulations for the Ambulance Corps of the United States Army. All the subjects are treated in a thoroughly practical manner, and the book will prove indispensable to all who follow camp life.

Jahresberichte über die Fortschritte der Anatomie und Physiologie. XX. Band, Literatem, 1891. II. Abtheilung. Physiologie mit General-Register zu Band XI.–XX. Leipzig: Verlag von F. C. W. Vogel. 1893.

With the present volume and its very complete index, this valuable publication ceases to appear.

Department of the Interior, Census Office. — Vital Statistics of New York and Brooklyn, Covering the Period of Six Years ending May 30, 1890. By John S. Billings, Surgeon United States Army, Expert Special Agent. Quarto, pp. 529. Washington, D. C. 1894.

This exhaustive report presents a number of interesting features which are quite novel in the line of census work, notably such as the subdivision of the city into sanitary districts, and the analyzation of the immediate surroundings of stated conditions upon the death rates of different races and classes of people. The influence of heredity, as derived from the mother is also shown. Aside from an almost bewildering array of figures, their analysis as bearing upon the conditions and influences named, a number of finely executed full-paged maps of New York and Brooklyn, are given, with the subdivision of sanitary districts proportionately shaded to illustrate the different degrees of death-rate from different diseases, accidents, suicides, etc. Age appears to be one of the most important factors. Deaths of the very young and very old take the lead. Of the male population in both cities over fifteen, over one-half are married. The death-rate was greatest in the widowed and least among the single. The death-rate of consumption was nearly equal in both sexes, being most fatal among the accountants and clerks, dressmakers and seamstresses, while suicide was most frequent among the school teachers in New York. Statistics are also presented of all other diseases in their varied and complex relations, affording an amount of instructive and valuable information which reflects the highest credit upon the minute and painstaking methods of the talented and accomplished compiler. The work can be studied with the greatest profit by the sanitarian and economist.

Hydatid Disease, Vol. II. By the late John Davies Thomas, M.D. (London), F.R.C.S. Eng., etc. Edited by Alfred Austin Lendon, M.D. (London), Lecturer on Forensic Medical and Clinical Medicine, University of Adelaide. 8vo, pp. 166. London: Baillière, Tindall & Cox. 1894.

This volume consists of a collection of papers on hydatid disease by the late Dr. Thomas, and presents a well-arranged account of the affection as related to the abdominal organs, thoracic viscera, nervous system, bones, muscles, etc. The clinical phenomena are also clearly presented, and the treatment by operative procedure is clearly detailed. The first volume of the series was the introductory one by the editor, while the present one contains wholly the views of Dr. Thomas.

Transactions of the Fifteenth Annual Meeting of the American Laryngological Association, held in New York, May, 1893. 8vo, pp. 165. New York: D. Appleton & Co. 1894.

This volume contains much that is interesting to the laryngologists. The papers of Dr. Delavan on neglect in reporting cancer operations, of Dr. Lefferts on intubation in the adult, of Dr. Lincoln on recurrence at a new site of a laryngeal growth, and of Dr. Jonathan Wright on the structure of œdematous nasal polypi, are worthy of special note.

Manual of Practical Anatomy, in Two Volumes. By D. J. Cunningham, M.D., Professor of Anatomy, University of Dublin. Edinburgh and London: Young J. Pentland. 12mo, pp. 647. Philadelphia: J. B. Lippincott.

This is a well-arranged, carefully written, and well illustrated work on practical anatomy. The author proves himself to be a good teacher in his very natural method, and in the thorough appreciation of the wants of the student. In many parts of the work will be found most valuable suggestions for an easier and more direct manner of study than is usual with works of its kind. Much attention is deservedly given to topographical anatomy, particularly as applied to the abdominal organs. Many of the illustrations are entirely new, while all are good and to the point. It is exceedingly difficult to give anything strikingly new in a dissection manual, but the author has done a good part in infusing an individuality in the work which will commend itself to the reader.

Braithwaite's Retrospect, Vol. CIX., January to June, 1894.

This well-known volume contains the usual amount of valuable selections for reference which have given it such a well-deserved reputation among students and practitioners.

A Retrospect of Surgery, January, 1890, to January 1894. Prepared by Francis J. Shepherd, M.D., C.M., Surgeon to the Montreal General Hospital. 8vo, pp. 259. Montreal.

This is a little book of abstracts of the progress of surgery, reprinted from the *Montreal Medical Journal*, and contains a fair selection of the notable things done in that line during the past four years.

Die neuesten Untersuchungen über die Pathologische Anatomie und Physiologie der Tabes Dorsalis. Zwei Vorträge, von E. Leyden. Berlin. 1894.

This is a small monograph written to show that the author, first and many years ago, demonstrated the initial lesion of tabes to be in the posterior spinal roots. This is getting to be the modern view, but it is not yet entirely proven to be the true one.

Lehrbuch der Nervenkrankheiten für Aerzte und Studirende, von Professor Dr. H. Oppenheim, mit 220 Abbildungen. Pp. 870. Berlin: Verlag von S. Karger. 1894.

The reputation of Professor Oppenheim as a careful observer and writer, and his long experience in Charité wards and the clinics of Berlin, lead one to expect a valuable treatise from him. There are a good many treatises on nervous diseases now, each having some special merits. Perhaps the special merit of Oppenheim's is the care and detail which are given to the interesting but relatively rare diseases. Thus syringomyelia gets nearly as much space as cerebral hemorrhage. Brain parasites and sinus thrombosis get more than myelitis. The chapters on cerebral syphilis and locomotor ataxia are particularly good.

Turning to the practical side, we find absolutely no new suggestions or helpful advice. For epilepsy, neuralgia, tabes, etc., the same list of drugs, the same advice about diet, baths, and potash is given. The author shows himself keenly alert to every clinical phenomenon or pathological process, but he does not take a human and curative interest. This is the Teutonic way, and Americans who do like to help their patients as well as to make a local and pathological diagnosis, are accused of being shallow and credulous. Despite of our criticism in this respect, however, we do not hesitate to say that Oppenheim's work is the most systematic treatise which any German has written since the ancient days of Romberg. It is well and copiously illustrated.

Les Nouvelles Idées sur la Structure du Système nerveux chez l'Homme et chez les Vertébrés. Par le Dr. S. R. Cajal. Edition française revue et augmentée par l'auteur. Traduite de l'espagnol par le Dr. L. Azoulay, Préface de M. Mathias Duval. Avec 49 figures dans le texte. Small 8vo. Pp. 200. Paris: C. Reinwald et Cie. 1894.

Professor Cajal's name is identified with some of the most important of the recent advances in the anatomy of the nervous system obtained by the application of metallic stains. Cajal himself is one of the very few modern Spaniards who have obtained an international reputation. No one could better present the new ideas of the structure of the nervous system, and the present work fulfils its purpose admirably, being clear and explicit without being cumbersome. The author adds descriptions of various new methods of staining.

Society Reports.

THE BRITISH MEDICAL ASSOCIATION.

Sixty-second Annual Meeting, held at Bristol, July 31 to August 4, 1894.

Special Report for the MEDICAL RECORD.

(Continued from page 251.)

SECTION OF OBSTETRIC MEDICINE AND GYNECOLOGY.

FIRST DAY, WEDNESDAY, AUGUST 1ST.

DR. J. G. SWAYNE, the President, delivered a short introductory address. He reviewed, historically, previous meetings of the Association at Bristol, and referred to his address in 1883, when he insisted on the importance of midwifery, and that it should stand next to medicine and surgery, and not be considered a specialty. Since then a new race of gynecologists and abdominal operators had sprung up.

He drew attention to the fact that medicine and surgery formed the subject of an address each year, but that obstetric medicine only occasionally did so, and thought that that was wrong.

Induced Labor in the Absence of Dystocia.—DR. ROBERT BARNES, of London, opened a discussion on "The Necessity of Inducing Labor in Certain Conditions of the Mothers not Obstructing Delivery." He said that as medical science advanced this was a matter which needed revision. We should study the methods of nature in adopting this means of relief; the safety of the mother should be our first consideration, and of the child the second, but frequently the two conditions ran together.

The duty of the physician when the pregnant woman was in difficulty was to consider the means of safety for both mother and child, and no problem in medicine was more difficult.

The most remarkable phenomena of pregnancy were increase in the excitability of the nervous system and increase in the blood and in the blood-pressure. We must recognize that the struggle between pregnancy and the coexisting disease was strictly physiological.

We must keep a strict watch over each organ, but be careful not to press expectant treatment too far. Several of the conditions were those which attended excessive nerve tension, and were of a convulsive character, of these the first one was vomiting; this was like other convulsive attacks and tended to be rendered chronic, each attack helping to graft a habit of vomiting.

Vomiting, in his experience, was most severe in cases where there was nerve shock or depression; rapid disintegration of tissue followed persistent vomiting, and this tended to cause a condition of toxæmia, ending in coma and death. Vomiting may throw excessive strain on the brain and cause cerebral hemorrhage. When rapid emaciation with toxæmic symptoms occurs, the induction of labor may prove too late. In cases in which the vomiting is due to excessive distention of the uterus, labor should be induced early.

Tetanus was a strong indication for the induction of labor. In chorea he thought that pregnancy should be terminated, and, as a general rule, one should not allow pregnancy in any convulsive disorder to continue. In insanity he would induce labor, though Dr. Savage was of a different opinion.

Vascular disorders, the excessive blood-pressure found in pregnancy, was sometimes relieved by external hemorrhage as epistaxis, by serous effusion, or by vomiting, throwing off some fluid, or by dropsical effusion, or might result in cerebral hemorrhage. For the excessive blood-pressure we should purge, and in some cases venesection was strongly indicated, and, as a last resource, we might induce labor.

Extreme anæmia might render induction necessary, or it might be required when valvular disease of the heart or aneurism was present. We should carefully watch these cases and induce labor when distress supervened. He believed that pregnancy aggravated phthisis, but the question of inducing labor was a difficult one. When tumors coexisted, as a general rule it was safer to let pregnancy go on. Repeated labors with a dead child suggested the bringing on of labor in a succeeding one before death occurred, and he believed that carrying a dead child was injurious to a woman. In scarlet fever he would induce labor if albuminuria were present.

In conclusion, he would urge the rule laid down by Denman, never to perform the operation without a consultation beforehand.

THE PRESIDENT said that in an experience of fifty-two years he had induced labor 37 times; in 24 of these cases it was done for contracted pelvis. In the remaining 13, 5 times for persistent vomiting, 3 for anasarca and albuminuria, 2 for hydramnios, 1 for vaginal hemorrhage, 1 for severe irritability of bladder, 1 for diseased placenta.

DR. MORE MADDEN, of Dublin, said that where the child had died in previous pregnancies he would induce labor as early as the sixth month, and he believed that at that time the child would be viable. As regards method, he preferred that of dilating the cervix by the finger.

DR. MURPHY, of Sunderland, thought the most frequent of the cases under discussion were those of grave albuminuria. As regards method, where no hurry, he would rupture the membranes; where rapid delivery was required, he would use Barnes's bags. Where the bag could not be introduced he would start with a tent.

DR. MURDOCH CAMERON, of Glasgow, would take exception to the induction of labor in fevers. With respect to uterine tumors he would not be inclined to interfere, unless the tumor were likely to obstruct labor. You may remove the tumor without interfering with the pregnancy. He did not think the child was viable before the seventh month, and the nearer the eighth month the labor was induced, the better. In ascites it was sometimes necessary to induce labor. In hemorrhage and eclampsia he had no hesitation in inducing it, although some were still disinclined to induce it in eclampsia. He thought some cases of violent vomiting were lost by delay.

DR. HEYWOOD SMITH, of London, would not induce labor in cases of fibroid tumor.

MR. J. W. TAYLOR, of Birmingham, called attention to cases of dropsy and albuminuria before the child was viable, and thought that these were the cases in which it was most desirable to have some settled rule laid down.

DR. MASSEY, of Bournemouth, related a case of severe dropsy in which he had induced labor by passing a catheter between the membranes and uterine wall with good result.

DR. BYERS, of Belfast, agreed in inducing labor in cases of vomiting which persisted in spite of treatment, but thought that all were not agreed that, given albuminuria in pregnancy, induction of labor should be decided upon.

He related three cases of primiparæ all with albuminuria and dropsy: 1. Dead fœtus, no interference, good recovery; he did not interfere because the fœtus was dead and there was no high-tension pulse. 2. Primipara, sixth month, one-fourth col. albumin, no high-tension pulse, no marked œdema; treated by warm baths and milk diet; living child at term; good recovery. 3. Much headache, high-tension pulse, labor induced.

Cases like the third were more troublesome because eclampsia was likely to follow. Recently Smyly, at the Rotunda, had found that in a large number of cases of eclampsia equally good results were obtained by leaving pregnancy alone and injecting morphia hypodermically.

DR. WRIGHT, of Leeds, had in one case been obliged to induce labor for severe ptyalism. In ovarian tumors would remove tumor and leave pregnancy. Would use solid bougie instead of catheter.

Dr. Aust Lawrence, of Bristol, urged necessity of first inquiring if vomiting were due to any other cause; had seen cases in which it was due to acute yellow atrophy of liver. Urged importance of giving a good trial of other treatment, especially of moral suasion; would be very chary of inducing labor in fever.

Dr. Tweedy, of Dublin, said that in the Rotunda Hospital the induction of labor was looked upon as a dangerous proceeding only to be resorted to in extreme cases, and it was seldom done except for contracted pelvis.

Recently a woman was admitted with fibroid tumors at the seventh month; a Porro's operation was done at term. He believed that in only two per cent. of cases of albuminuria did eclampsia follow, and they did not induce labor at the Rotunda in cases of eclampsia in pregnancy, but treated the condition by hypodermic injection of morphia, one-half grain every half-hour, with very good results.

He had never seen a case of death from vomiting in pregnancy. In ovarian tumor in pregnancy he would open abdomen and remove tumors.

Dr. M. A. Scharlieb, of London, had twice done ovariotomy in pregnancy with good results.

Dr. Boxall, of London, had induced labor in one case, because of varicose veins in vulva which threatened to burst. Would be very diffident in interfering in cases where fibroid tumor complicated pregnancy.

Dr. Pearse, of Southsea, thought that a mistake was often made in waiting for a viable child, and that the condition of the mother should alone decide the necessity.

Dr. Barnes, in reply, said that he had seen cases of vomiting prove fatal. As regarded method, preferred bougie to catheter. He did not think digital dilatation desirable. There was no class of cases in which the induction of labor was always necessary, and he did not advocate it in all cases of albuminuria. In convulsions, he thought inhalation of nitrite of amyl the best treatment. He would retract now an opinion he expressed years ago, and would say that when there was ovarian tumor and pregnancy, you should remove the tumor and not the pregnancy.

Uterine Fibroids.—Dr. M. A. Scharlieb, of London, then read a paper on "The Treatment of Uterine Myomata." She gave an account of the operative proceedings in nineteen cases. In six she removed the appendages, and all recovered. In thirteen she removed uterine tumor and appendages, and two proved fatal. In one she removed tumor only. In the first six cases she removed the tubes as close to the cornua as she could.

In the cases of hysterectomy she first ligated the broad ligaments outside the appendages, then ligated the uterine artery. She made flaps of the peritoneum on anterior and posterior surfaces of uterus, and she carefully disinfected the cervix with pure phenol. She closed the abdominal wall with three separate layers of stitches. In four she used a temporary elastic ligature, and in all these she drained. In the remainder she tied all bleeding points and did not drain.

The lessons she drew were: First, the importance of thorough surgical cleanliness.

In her cases the patient had repeated hot baths first, then the skin was disinfected by washing with soap and water, alcohol, solution of permanganate of potash, followed by oxalic acid. Then 1 to 2,000 corrosive sublimate, and lastly a carbolic compress was left on for twenty-four hours. The clothes worn by the patient were also sterilized. The operator and assistants cleansed their arms and hands in the same way as the patient's abdomen was done, and wore sterilized linen overalls. The instruments were boiled and laid in 1 to 20 carbolic, which was diluted with boiling water at the time of operation, and they were put down during operation in a shallow dish containing carbolic. The sponges were cleansed with sulphurous acid and kept in carbolic.

The second lesson to be learnt was the importance of handling the peritoneum as little as possible; she did not believe in sponging or mopping the peritoneum, and thought that doing so encouraged hemorrhage. She avoided the temporary elastic ligature as much as possible, because she thought that there was more oozing afterward. She avoided drainage as much as possible.

The third lesson was to tie the arteries, both uterine and ovarian, carefully; and the fourth, to treat the stump intra peritoneally.

In all cases there was no sepsis, and the two which proved fatal died from shock. She did not leave a ligature on the stump; because it caused death of tissue. She drew attention to the fact that only one of the cases was the mother of children, the remainder being unmarried or sterile.

Resection of the Uterus.—Dr. J. Stuart Nairne read a paper on "Resection of the Uterus for Fibroid Tumors and other Diseases." He pointed out that removing the appendages did not always restore to health, that enucleation of the tumor per vaginam or by abdominal incision was dangerous and the results not always satisfactory. He would propose what he called resection, namely, to split the uterus, remove the tumor, and stitch the remains of the uterus together, tying the vessels as he met with them. He had treated three cases in that way, they had recovered and one had since had a child.

Extirpation of the Uterus for Myomata.—Dr. Smyly, of Dublin, read a paper on "Total Extirpation of the Myomatous Uterus." He said that the treatment of uterine myoma was still one of the burning questions of the day, but that he in this paper would deal only with the last resource of surgery. He would advise, however, that those who were beginning to do hysterectomy should adopt the extra peritoneal treatment of the pedicle; this was the only method he adopted up to 1892, since then he had only done one case in that way. What he did now was to perform total extirpation in one of three ways: By abdominal section, per vaginam, by a combination of the two, or the "mixed method." The dangers of hysterectomy depended on the stump, and by adopting this method these dangers were removed. He had done fifteen cases with two deaths. By the mixed method, eleven cases with one death. By the abdominal method, two cases with one death. By the vaginal method, one case, no death. Some very large tumors among them. One where the uterus was as large as a full-term pregnancy and contained several myomata was removed in this way. He opened the abdomen, ligatured the broad ligaments, then divided the pouch of Douglas, and lastly separated uterus from bladder.

In small tumors he had removed the uterus per vaginam by morcellement, and in one case the fragments weighed two and a half pounds; for two days beforehand the vagina was packed with antiseptic gauze, patient was placed in lithotomy position, and cervix drawn down and separated from bladder. Pouch of Douglas then opened and cervix cut away, and then uterus attacked.

Dr. Heywood Smith, of London, congratulated Mrs. Scharlieb on her success; he thought that soon all cases would be treated by the intra peritoneal method or by complete extirpation. Vaginal hysterectomy showed a less mortality than any other method, but the best way of dealing with these tumors was not yet determined.

Dr. Rabagliati, of Bradford, related a case in which a large fibroid disappeared after pregnancy, and thought that now too much attention was directed to surgical treatment, and too little to dietetic and medicinal.

Dr. Cullingworth, of London, drew attention to the extreme care which Mrs. Scharlieb paid to the prevention of sepsis, and said that the method resembled that adopted in the Johns Hopkins University Hospital, as published by Dr. Howard Kelly; and the same precautions had been adopted in a maternity at Clapham, carried on by ladies, with excellent results. He complained that there were not sufficient statistics at present to enable one to decide whether hysterectomy was justifiable or not, and that what we really want is an authentic history of a number of cases not treated surgically; opera-

tions were more frequent now because we know that these tumors sometimes kill, but many disappear without operation.

Dr. Travers, of London, thought that cases after hysterectomy were never so well able to work for their living as after other abdominal operations.

Dr. Aust Lawrence, of Bristol, thought that the station of life of the patient often determined the treatment. Thus hysterectomy was required in the poor woman, whereas a well to do one who could lay up might avoid the operation.

Dr. Barnes, of London, would like an authoritative opinion as to whether a fibroid tumor ever killed, as it had recently been stated by a prominent London physician that they never did so.

Mrs. Scharlieb, in reply, said that one seldom found the appendages healthy in cases of myoma; in nearly all her cases the ovaries were enlarged and cystic. The question of removal of the appendages of the tumor depended on the nature of the growth. Thus in large, smooth, uninodular tumors removing the appendages did not check the growth; also multinodular tumors, when of large size, needed the major operation, though in two or three of her cases the electrical treatment had been used and had proved futile. She thought that there was no doubt that fibroids did sometimes kill by the hemorrhage and pain, or by pressure on the ureters. Her patients had been able to return to hard work after the operation, and no hernia had resulted in any of her cases.

Second Day, Thursday, August 2d.

Hemorrhage in Late Pregnancy.—Dr. Smyly, of Dublin, opened a discussion on "The Treatment of Hemorrhage during the last Two Months of Pregnancy." He said that in the great majority of cases this was due to separation of the placenta; the uterus was divided into two distinct portions, and this difference which existed in pregnancy was most apparent after parturition. The upper thick portion received its blood-supply directly from the uterine and ovarian arteries, and the lower thinned portion, to which the blood vessels passed, from the upper segment. The limiting line was called the retraction ring; the placenta was sometimes situated in the lower segment, but wherever its situation premature separation of it caused hemorrhage. It was not possible always to draw a line between accidental and unavoidable hemorrhage.

Placenta prævia occurred in women who had borne several children rapidly, also in connection with an enlarged and diseased uterus. The placenta was seldom normal in these cases. It was thinned. There were often spaces in which its tissue was deficient, and placenta succenturiata occurred. He thought that an abnormally low attachment of the placenta might be attributed to four causes: 1. When there was a very large placenta which could not find room in the uterus. 2. When the uterine walls were concave inward, instead of convex, as they should be, and there was an actual instead of a potential cavity. 3. The stretching of the cilia in endometritis. 4. The placenta being developed from decidua reflexa.

The diagnosis was made from the hemorrhage and from feeling the placenta. He did not believe that auscultation was of any value for diagnostic purposes. The hemorrhage before labor may be due to a disproportion between the placenta and the area of its site. Hemorrhage during labor was due to the distention of the lower uterine segment, and its being drawn up by the action of the longitudinal fibres, and the detachment of the placenta may cease with the rupture of the membranes.

Treatment.—In almost all cases the os will admit two fingers; if so, bring down a leg and then leave the case to nature. If further hemorrhage occurs, gentle pulling on the leg will arrest it. There were two conditions in which this treatment was inapplicable: 1. When the os would not admit the finger; in these he would plug the vagina. 2. When the labor was advanced and turning impossible. In these he would rupture the membranes. He did not recommend any other methods, and disapproved of accouchement forcé and separation of the placenta by the finger. The method which was common was bad, viz., to plug the vagina until the whole hand could be introduced, and then to do internal version. This was attended by many dangers, among which he would mention sepsis, entrance of air into veins causing sudden death, and laceration of the cervix.

The mortality of the method he had described had been seven per cent. Of twenty cases lately treated two had died.

Accidental Hemorrhage.—He did not think that an accident would cause separation of a healthy placenta. The commonest cause of this condition was disease of the endometrium, and this was frequently asscciated with syphilis and renal disease. The blood vessels were diseased and caused hemorrhage, and this went on if the blood had not free escape until the pressure to which it was subjected equalled the blood-pressure in the maternal vessels. He thought that concealed accidental hemorrhage was due to some disease of the uterine wall, which rendered it unable to resist the pressure of the effused blood, and on that account he looked upon it as dangerous because it always betokened a diseased atonic uterus.

Treatment.—It was impossible to lay down a routine treatment, and he thought that the importance of rupturing the membranes had been overestimated, and this was only useful when labor was somewhat advanced. Some cases required nothing to be done. When the os was small he thought that rupturing was bad, as it reduced the pressure in the uterus and so favored further hemorrhage. It does not always induce pains, and so blood flowed into the partially emptied uterus. It is better in severe cases to combat shock, and where blood is escaping from the uterus to use vaginal douches of hot water, followed by a vaginal tampon. He did not think that the tampon favored concealed hemorrhage. After rupturing the membranes he would never use tampons. In very bad cases he believed that Porro's operation would be better than accouchement forcé.

He epitomized his treatment thus: When os small, preserve membranes; when hemorrhage appeared externally, plug; when labor advanced, rupture membranes and deliver by the best method possible.

Dr. Robert Barnes, of London, believed that disease of the uterus was the most common cause of hemorrhages; but that disease of the placenta was also a cause. In placenta prævia he would not use accouchement forcé. He described the retraction ring long before Bandl. He looked upon placenta prævia as resembling ectopic gestation, in that the placenta was fixed to a part which was not adapted to receive it. When the os was small he used his own bags. He always preferred forceps to version, where possible, as it gave a better chance to the child. He did not like the use of the vaginal plug.

Dr. Byers, of Belfast, had met with cases of placenta prævia in which the os would not admit the fingers, and in three such cases he had tried De Ribes's bag with good results. After introducing the bag, if labor did not come on, he had found that gently pulling on the bag would hasten it, and would arrest any hemorrhage. He had found that he could introduce De Ribes's bag when the os was the size of a shilling. In accidental hemorrhage rupture of the membranes only did harm when pains did not quickly follow.

Dr. More Madden, of Dublin, was opposed to a good deal that Dr. Smyly had said, and he advocated accouchement forcé and the vaginal plug; for the latter purpose he used a clean sponge soaked in terebene. After sufficient dilatation had been obtained he performed internal version, never using bipolar method. In accidental hemorrhage he saw no objection to rupturing the membranes.

Dr. Murphy, of Sunderland, said that we should rec-

ognize the danger of placenta prævia, and if the seventh month had passed take the case in hand at once. He had always found in cases of placenta prævia that the finger could be introduced into the cervix. He then separated the placenta for a short distance around the os and put in a Barnes bag, and as soon as sufficient dilatation had been obtained he delivered. He thought that the place to put in a plug was the cervix, and not the vagina.

Dr. Murdock Cameron, of Glasgow, entirely disapproved of Porro's operation in any case of accidental hemorrhage. He advocated the vaginal plug. He had never seen a case of concealed accidental hemorrhage. When the placenta was central he always pushed his fingers straight through its substance.

Dr. Scharlieb, of London, believed in plugging with iodoform gauze.

Dr. Robert Boxall, of London, had investigated the point on the membranes which presented over the os by touching it with eosine at an early stage of labor, and locating the stained spot afterward. He found that in many of these cases the placenta must have encroached on the dangerous zone, though there were no symptoms of placenta prævia, and the latter was especially the case when the membranes ruptured early. In some cases external version was possible. He drew attention to the fact that an accident was sometimes the cause of hemorrhage in placenta prævia marginalis. He had examined a large number of placentæ, and in several cases had found evidence of hemorrhage having occurred a month or two previously, when there had been no symptoms. He impressed the necessity of inducing labor when hemorrhage had once occurred. In cases where there was no dilatation of the os, the hot douche proved useful. In some cases he plugged the vagina, using wool soaked in sublimate solution. He had seen cases in which the placenta covered the greater part of the interior of the uterus.

Dr. Aust Lawrence, of Bristol, said that when the cervix would not admit the finger he was in the habit of plugging the cervix with iodoform gauze. He thought cases in which there were repeated small bleedings were more dangerous than those in which the hemorrhage was at once alarming. He would never leave the woman until labor was finished when once bleeding had set in.

Vaginal Hysterectomy for Cancer of the Uterus.—Mr. F. B. Jessett, of London, then read a paper entitled, "On Thirty Cases of Vaginal Hysterectomy for Carcinoma Uteri, with Two Deaths." He said that vaginal hysterectomy was now a well-recognized operation, and was done in three ways: 1, using ligatures; 2, using clamp; 3, combined abdominal and vaginal method. He laid great stress on the importance of suitable preparation of the patient beforehand. He would have her kept in bed three or four days, and syringe vagina frequently. He dusted iodoform of cervix through a Ferguson speculum, especially if there was ulceration. The diet should be light.

Details of Operation.—Patient in lithotomy position, using Clover's coutell. Two Sims specula were passed, one in front and one behind. A sharp hook seized the anterior lip of cervix and pulled it down, and cervix was seized by two vulsella. A sound was passed into the bladder to determine its limits. Strong scissors then divided the mucous membrane around the os. The bladder and ureters were separated by the fingers, special care being taken to free thoroughly at the sides. The utero-vesical fold of peritoneum was opened. Then Douglas's pouch was opened and the fore-finger of the left hand passed behind and the thumb in front of the broad ligament, and the uterine artery on each side recognized. A special strong curved needle was passed up at the front of the broad ligament and pushed through above where the uterine artery was felt, threaded, and withdrawn, and ligature tied. A pair of pressure forceps was applied between the uterus and the ligature and the broad ligament divided with scissors. The fundus was anteverted or retroverted so as to bring the ovaries into view, and the remainder of the broad ligament transfixed and tied in two sections, the ends of the ligatures being left long and brought down through the vagina. The anterior and posterior peritoneal flaps were seized with catch-forceps and brought down. A glass drainage-tube was passed into the peritoneal cavity and the vagina plugged. The plugs being removed on the second day.

In two cases the uterus was so large that it could not be removed through the vagina entire. In these cases it had been advised to divide the uterus in half, but he preferred to treat them by the combined method. The patient being in the same position, the operator stands between her legs to make the abdominal incision. The uterus was then drawn up and the broad ligaments tied.

As to the question of clamp and ligature, he preferred ligature, but he thought that in cases where the patient was very exhausted the clamp might be used, as it took a shorter time. He had invented a special clamp for the purpose.

Apex Treatment.—If prolapse of omentum or intestine occurred, he used the speculum; packed the vagina daily, and used douching. He had the bowels open on the third day. He found it necessary to tie a catheter in the bladder for at least two days.

As regards the results, cases only were fit for this operation in which the disease was limited to the uterus, and the latter was freely movable.

The advantages of the clamp were that the operation was more rapid. Its disadvantages were that the end projected into the peritoneal cavity and might convey septic matter. That it inevitably led to necrosis of the tissues it grasped. That intestinal obstruction was more frequent after its use, and that the ureters might be caught between its blades. Also, that the weight and discomfort to the patient occasioned by its use were considerable.

As regards silk and catgut for ligatures, he preferred silk for the uterine artery, but for the remainder of the broad ligament catgut might be used. He did not stitch the peritoneal flaps, but drew them down into the vagina and carefully packed around them.

As regards drainage, he thought that if there was much oozing it was safer to use a glass drainage-tube. If gauze were used, the omentum might be entangled in it and drawn out. Flushing the peritoneum was useful.

The dangers of the operation were sepsis, hemorrhage, and injury to ureters. This might be avoided by being careful to thoroughly separate bladder, and by taking care to pass the needle from before backward. Vesico vaginal fistula might result, or recto-vaginal fistula in virginal narrow vaginæ. In cases of cauliflower growth he would remove the growth before doing hysterectomy. He did not think it necessary to remove the ovaries and tubes.

Dr. Smyly, of Dublin, had sometimes had occasion to regret having performed the operation when the disease had been too extensive. The principal guides as to the amount of extension of the growth were that the uterus should be mobile and the broad ligaments not invaded by the growth, as shown by examination per rectum. He preferred the method of Dr. Doyen, of Rheims. Both flushing and suturing of the peritoneum were usually unnecessary.

Dr. Heywood Smith, of London, drew attention to the danger of inverting the uterus when the disease was in the cervix, as being likely to infect the peritoneum; and said that ligature was almost impossible when the vagina was narrow. He would use the catheter as little as possible.

Dr. Aust Lawrence, of Bristol, drew attention to the importance of recognizing that cancer in an early stage is curable, and of making an early diagnosis.

Dr. Scharlieb had found the clamp cause much pain and discomfort, and was of opinion that it retarded recovery.

Dr. Jessett, in reply, said that in cases which had extended too far for operation, he would use the curette and

pack the cavity with chloride of zinc, which brought away a slough of the diseased tissue.

Dr. More Madden, of Dublin, read a paper "On Primitive and other Hyperæsthetic Conditions of the Vulva and Vagina." The paper was devoted almost entirely to the treatment of these conditions. He advised particularly cleanliness; the use of germicides, as corrosive sublimate, and the application of methylene blue to the parts. He had found this latter do much good, but the disadvantage was the coloration produced, which was difficult to remove. In dyspareunia he advocated forcible stretching under ether.

Hæmatometra.—Dr. Murphy, of Sunderland, read a paper entitled "Notes of a Case of Hæmatometra successfully Treated by Hysterectomy."

Patient, aged forty two, married; never menstruated; tumor reaching two inches above umbilicus; has been forming some months. On vaginal examination finger passed two inches and was then stopped by a septum, which was found to be the hymen unruptured. No swelling could be felt above this, and no uterus could be made out on rectal examination. The tumor in the abdomen was thought to be ovarian. On opening the abdomen the tumor was found to be uterus distended with menstrual blood and with os occluded.

Menstruation.—Mr. E. T. Collins, of Cardiff, read a paper on "The Nervous Impulses Controlling Menstruation and Uterine Hemorrhage." His observations went to prove that there was a nerve-centre, but that its action was reflex and not automatic, and depended on irritation from the uterus.

Third Day, Friday, August 3d.

Separation of the After-coming Head.—Dr. Purslow, of Birmingham, read a paper entitled "An Account of Four Cases in which Separation of the After-coming Head had Occurred during Delivery, and of the Means used to Extract the Head." He narrated the cases: The first three occurred in connection with premature delivery before the sixth month, and the head came off owing to obstruction from a tight cervix. In none of the cases was there any sign of life in the child. One of the heads was extracted by the finger, and the other two by ovum forceps. In the fourth case the child was fully developed, but decomposed, and there was some narrowing of the pelvic brim; the child had presented by the breech, and in endeavoring to extract the head came off and was left in utero.

Dr. Purslow saw the case four hours later, after several attempts had been made to extract by forceps and crotchet. He extracted by the cephalotribe after very considerable difficulty, the difficulty arising from the tendency of the blades to slip off, owing to the difficulty of applying them over the centre of the head, and from the fact that when they were applied the lock was one and one-half to two inches within the vulva. The patient made an excellent recovery. He reviewed the methods of extraction advocated by ancient and modern authors, and concluded by advising recourse to the cephalotribe as the best means of delivery. Some of the other methods advocated involved bringing the head down in such a position that the jagged protruding ends of the fractured cervical vertebræ were apt to seriously injure the vaginal or uterine wall.

Ectopic Gestation.—Dr. Cullingworth, of London, read a paper "On a Case of Advanced Extra-uterine Gestation in which a Living Child was removed, the placenta left Undisturbed, and the Abdominal Wound entirely Closed." He said that it was sometimes advised in these cases to wait for the death of the child before operating, so as to allow the placental circulation to diminish. It had been advised at the operation to leave the placenta with the cord protruding from the abdominal wound. It had been proposed by Lawson Tait to leave the placenta to undergo absorption; the attachment of the placenta at the operation was dangerous, because the attachment of the placenta differed from that found in the uterus, and in ectopic gestation, there was no mechanism for arresting hemorrhage when it was detached. That absorption could occur was proved by those cases in which the fœtus had died. No operation had been performed and everything, with the exception of the bones, had disappeared.

In his case the child was alive at operation, the opening in the membranes was sutured, and the cord cut short. There was satisfactory progress for three weeks, on the twenty-fourth day a rigor occurred, and on the twenty-sixth day he opened the abdomen. He found purulent fluid in the remains of the amniotic sac, he washed out, but the patient died the same day.

Autopsy.—No suppuration in substance of placenta; child still alive and well. In future operations he would allow bleeding from the divided end of the cord, so as to lessen size of placenta; would divide cord quite close to placenta; would remove all the amnion possible, stripping it off from the placental surface, as the sepsis in this case arose from the remains of the amniotic sac; and it would teach him to remove parts not likely to cause hemorrhage in their removal, but likely from their non-vascularity to decompose.

Dr. Aust Lawrence narrated two cases in which he had operated; in one the placenta was absorbed and patient recovered; in the other there was septicæmia and death on the twenty fourth day. He would leave the placenta, and if there were symptoms would reopen the wound.

Dr. Cullingworth, in reply, said he would be on guard for septic symptoms and reopen abdomen at once. It was a difficult matter to decide, in cases in which the fœtus had died, how soon afterward to operate. He had operated four weeks after and removed the placenta with perfect ease. Drainage should not be used if any hope were entertained that the placenta would absorb. He would strip off amnion right up to margin of cord and cut the latter off as close as was possible.

Pseudo-ovarian Disease.—Dr. Rabagliati, of Bradford, read a paper on "Some Obscure Ailments which Simulate Ovarian Disease; their Causes and Treatment." The cases he described were often called ovarian neuralgia. There was pain in ilio lumbar region, pain in head, menstruation tending to be profuse, slight leucorrhœa, and these symptoms persisted for years. On making an examination the tissues were flabby; they were suffering from "diseases of a lax fibre" and deficient nutrition of the affected parts, and the essential cause of these sufferings was rheumatism of the muscle sheaths of the fibres of the abdominal and pelvic muscles.

The affected muscles, especially the rectus, were tender to pressure. On passing the finger into the umbilicus, a slight opening was felt, the edges of which were sharp and very tender. There was tenderness on pressure over the erector spinæ muscle and over the sacro-iliac synchondroses. The pectoral muscles and those at the back of the neck were also tender. The causes of the condition were malnutrition, especially too little nitrogeneous food. The symptoms were not due to hysteria. Treatment consisted in feeding and movements of the muscles under pressure; these latter the patient was instructed to do herself, and photographs were exhibited to show how the movements were performed. Cold baths were also used, and by these means Dr. Rabagliati said he had cured cases for whom removal of the ovaries had been advised.

The Section was then adjourned.

Curiosities of Cholera.—It is a fact of the various cholera epidemics that have swept Europe, that in every one the mortality at Rome and Madrid was greatest on Sundays, at London and Berlin on Wednesdays, and at Paris on Saturdays. At present, in St. Petersburg, where the death rate is upward of one hundred daily, the mortality list is increased one-fourth on Saturdays.—*Medical Age.*

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, April 6, 1894.

GEORGE L. PEABODY, M.D., CHAIRMAN, *pro tem.*

Chronic Double Parotiditis—Two Cases.—DR. ROBERT ABBE presented a man and photographs of this and another case of chronic double parotiditis. The first case, of which photographs alone were shown, occurred some years ago in a man whom he had first seen, as he was reminded later, in the practice of Dr. Weir. The enlargement of the parotid glands had persisted during the entire time the patient remained under Dr. Abbe's observation, perhaps a year and a half. Had at no time been attended by very acute symptoms; no suppuration. The man presented was the only other similar case which had come under his observation. The glandular enlargement had existed over a year, and had come on without apparent cause, although on account of the rapidity of its development Dr. Abbe had at first supposed it was due to mumps, a view which proved to be incorrect. Last summer the man had had an attack of appendicitis, but recovered after about two weeks, and was able to resume business in Wall Street until about two months ago, when he had another attack of appendicitis, for which Dr. Abbe operated and removed the suppurative appendix. Since that date the man had felt better than at any time for two years, had gained about twenty-five pounds in weight; but there had been no change in the parotid glands except that the swelling was a little more diffuse and a little softer, but contained no fluid.

In the first case the entire parotid had been involved; in the second only the upper portion in front of the tragus and lobule.

DR. WEIR remembered the first case, of which he said Dr. Abbe took the photograph for him. The swelling was harder than in the case of the man presented, was of the entire parotids, which were swollen in equal degree. Surgical interference was not considered necessary. The present case reminded him of one recently seen in a patient from Montreal, in which, however, the suspicion of symmetrical fatty tumors was confirmed by the presence of fatty growths in the neck.

DR. MCBURNEY was disposed to think, from the softness of the tumors, the presence of at least the greater portion of the parotid at a lower situation, and the fact that the man had been growing fat, that the case was one of lipomata symmetrical on the two sides.

DR. ABBE said he had had in mind the possibility of fatty tumors, but the growths had not been so soft in the first place; they had developed when the man was in his poorest health, before he had begun to take on flesh, and had remained of the same size since the first month.

DR. ANDREW H. SMITH remarked, incidentally to the question of symmetrical lipomatous tumors, that about seven years ago a patient entered the Presbyterian Hospital with seven or eight symmetrical lipomata in different parts of the body, there being two on the forehead, two on the neck, and others located symmetrically elsewhere.

Cholecystenterostomy by Murphy's Button—Recovery.—DR. ROBERT ABBE related the case. In October last Mrs. M——, aged forty five, had entered her fourth month of profound jaundice, with entire loss of appetite, emaciation, and exhaustion.

She had never had biliary colic, and the onset of this attack was unaccompanied by other symptoms.

Examination showed her to be very thin and deeply jaundiced. The gall bladder could be felt well distended. No other tumor was apparent.

Drs. C. W. Packard, Archibald Campbell, of Mt. Vernon, and I agreed that there was probably present obstructive pressure from cancer. As the patient's condition was critical I operated on the chance of finding stone obstruction, and to establish a new channel for the bile under any circumstances.

I found the common duct the site of a small hard mass no larger than the end joint of one's thumb. The gall-bladder was distended with a pint of black viscid bile; there were no stones in it.

The tumor was movable and could be pinched up between the thumb and fingers. It was hard enough to be a stone bedded in an inflamed duct, but needling and knife puncture showed it to be a small, hard neoplasm.

Further operation of any sort was prevented by the extremely low condition of the patient at this juncture, and an external bile fistula was quickly established. With assiduous care the patient rallied well under Dr. Campbell's attendance, and made an excellent convalescence. The jaundice quickly disappeared, strength and appetite came back, and she gained flesh. The duct obstruction remained absolute. Stools continued white, and a daily discharge of from fourteen to sixteen ounces of bile was caught in a thin rubber bag secured to the drainage-tube.

At the end of three months she was in good condition, and I operated to divert the bile into the duodenum. The gall-bladder was atrophied, but readily separated from the under side of the liver. Half a Murphy's button was put into a slit in the gall-bladder, and half in the duodenum six inches below the pylorus. The two were united and the abdomen closed. The purse-string suture of the thickened gall bladder made it a little difficult to draw the slit within the grasp of the button, but an outside stitch perfected the union.

Examination of the small tumor of the duct showed slight enlargement during the three months since first operation.

Uninterrupted convalescence ensued. The button was passed on the twelfth day.

Dr. Abbe also presented two specimens from the dog's intestine, one illustrating end-to end union after resection and the use of Murphy's button, the other long opening formed by lateral anastomosis. There was no doubt, he thought, but that the button could be used in the human intestine with greater security and a more perfect result than could be obtained by any other method with which he was acquainted. The rim of the button cut out a clean section of the gut, which did not show the tendency to contract which was observed after making a broad suture line.

DR. WEIR said fear had been expressed that some time one of the buttons might fail to pass and constitute an obstruction. It seemed, however, that experience had proven this objection unfounded in the end-to-end anastomosis. But it had been proposed to employ an elongated button for lateral anastomosis. In the speaker's opinion, the one shown and intended to accomplish this end would prove a failure, as it did not provide for long enough an opening. He inquired of Dr. McBurney what had been the result in the case at Roosevelt Hospital in which Dr. Murphy had himself made end-to end anastomosis with his button.

DR. MCBURNEY said the result had been successful, but other operations would have to be performed, as had been intended, before the patient could be dismissed from the hospital.

In reply to an interrogatory, DR. ABBE said the button came away in from seven to fifteen days. The quickness of the operation and security obtained by thus sandwiching together the ends of the intestine, recommended the method particularly to those who had not had great experience with the technique of abdominal surgery.

Cases in Genito-urinary Surgery.—DR. R. F. WEIR read a paper bearing this title. (See p. 161.)

A Medical Syndicate.—We read in one of the religious weeklies an enthusiastic notice of the adoption, by two churches, in a town in Iowa, of a plan of assessing every church member fifty cents a month; and in return offering free medical attendance and three dollars a week during illness, with the entire funeral expense in case of death.—*Polyclinic.*

Correspondence.

DR. EASTMAN'S METHOD OF SUPRAPUBIC HYSTERECTOMY.

To the Editor of the Medical Record.

Sir: In the current volume of the Medical Record, page 147, you speak of my address before the Gynecological Section of the American Medical Association, and say that my method consists of tying the uterine arteries in the broad ligaments close to the corner of the uterus. While the ligature in a given case may include the uterine artery, the whole point of originality which I claim was that the coiling arteries given off from the uterine artery nourished the uterus by a plexus, and not by penetrating the uterus; therefore, instead of ligating the uterine arteries at all, I go between them and the uterus, peeling out even the entire cervix, and only perhaps occasionally ligating some little spurting twig which has been abnormally enlarged.

If I had said anywhere that I ligated the uterine arteries, then there would have been nothing in my method to claim originality for. There may not be now, as others had already gone from below upward, peeling out the uterine cervix without clamp or ligature—notably Sauter, of Constance, Germany, three quarters of a century ago.

I repeat, the whole spirit of my essay, Section in San Francisco, read before the Michigan State Medical Society, was to prove that the coiling arteries of the uterus do not penetrate that organ, but are spread out over it in a capillary net-work, and that the uterine cervix can be peeled out from above downward without clamp or ligature to control hemorrhage.

Joseph Eastman, M.D.

Indianapolis August 13, 1894

BATHS IN INFLAMMATORY AFFECTIONS OF CHILDREN.

To the Editor of the Medical Record.

Sir: More than fifteen years ago you published an article of mine on the efficacy of balneotherapy in acute bowel affections seen so frequently, and so deadly, in the congested areas of cities during the heated term of summer. I have found this method as reliable as ever in my experience since that time. I first wrote on this subject in a report made to the Philadelphia *Medical Times*, in July, 1875, then edited by Professor H. C. Wood (where it appears under the head of "Correspondence"). and subsequently I made reports once or twice for the Medical Record.

The tropical heat of this summer, and the fearful rate of mortality in children under three years of age from entero-colitis, leads me briefly to recall my original publications. Dr. Wood, after a most successul use of baths in the Children's Hospital on the grounds of the Centennial Exposition, 1876, did me the honor to say (editorially), in 1877, in the Philadelphia *Medical Times*: "It must be granted to Dr. Comegys the credit of having introduced the most life-saving improvements in modern therapeutics."

The application of these baths is so simple that they can readily be applied in any house. We are summoned usually to see a child who has already been sick some time and undergone household treatment, and we find a hot skin; temperature, 102° to 104° F.; rapid pulse, 130 to 150; respirations, 30 to 40; with frequent vomiting and purging; tongue and mouth dry, intense thirst, insomnia, rolling of the head, and uttering distressing cries.

I direct an immersion bath in hydrant water, which with us in summer is about 75° F., and over the forehead and scalp, the head being held in the hand, is poured a stream of cistern water, 65° F. This operation is kept up for several minutes—eight to ten. In a little while the child ceases to cry and struggle, and it will drink greedily of water. Often the lips become bluish and the jaw trembles. After the bath, the patient should be put unwiped in a blanket. The sedative effects of the cold bath will speedily disappear, reaction is established, and the child goes to sleep promptly; the fever disappears, the pulse has lost its frequency, the breathing is slower and more natural, the vomiting and diarrhœa cease.

For several years past I have ceased to use cold water and rely entirely on hot bathing, always using a water two or three degrees above the fever temperature of the body, and keeping the patient submerged from six to ten minutes; still, however, pouring cold water over the head. I have made this change because the use of cold water is so much more painful or distressing to the little sufferers. When they are withdrawn from the bath they are wrapped in a soft and warm blanket, where they will sweat like a rain, and in this way the toxines which have accumulated in the blood, and so depress the cardiac, arterial, and capillary circulation, are eliminated and convalescent conditions are promptly established. In short, I have ceased to use cold baths in inflammatory affections of any form in young children.

I will not discuss internal medication, but barely mention small doses—one eighth grain—of calomel are very useful; or, what I like better, blue pill mixed with syr. rhu. aromat.; either remedy given in small doses every three hours. Food: Good milk and cream in equal parts and a certain amount of brandy every three hours. If a fresh air location can be obtained, there is very little danger of a relapse.

C. G. Comegys, M.D.

Cincinnati, O., August 13, 1894.

HYGIENIC TREATMENT VS "EAR-RUBBING," FOR "HAY FEVER."

To the Editor of the Medical Record.

Sir: A Hamburg physician (according to the *Deutsche Med. Zeitung*), whose condition from hay fever had been so severe as to necessitate his using a closed carriage all through the summer (sic!) has for the past three years "been able to lead an endurable existence during the hay-fever season," by means of roasting his own ears, so to say, "rubbing them till they became red and hot." "As soon as the least sensation of fulness in the nose appears, there is recognized a certain amount of pallor in the ears. A thorough rubbing of the ears, at times even to contusion, has always succeeded in freeing the nasal mucous membrane from its congestion. The rubbing must be thorough and repeated as often as the least symptom of congestion returns to the nose." The doctor declares that several patients have also been relieved by this method, and he hopes that some other physician may be able to give his patients some relief! This is indeed a worthy ambition. But from the writer's point of view, after years of the most complete success in the management of the disease by a perfectly rational method, Dr. Ferber's plan of relieving congestion of the nose by means of counter-irritation, getting up a congestion of the ears by rasping them till they are raw, seems pitifully absurd.

In view of all that we hear and see of this terrible enemy of the human race, it would seem that any remedy that will enable a victim of hay fever to "lead an endurable existence" in summer should be widely published; but any doctor who recognizes this disorder as a local fever, and does not directly cool his head instead of warming his ears, ought to have the latter soundly boxed—which, by the way, would answer in place of rubbing. (I should be sorry to have my prescription misinterpreted.)

Hundreds of hay-fever victims spend the summer at the White Mountains every year, where it is said the majority find great relief, and some, indeed, complete immunity from the disorder, in spite of the continuance of the very practices which provoke the disease further south, viz., winter dress and diet. At

the North Pole we may guzzle blubber and wear several layers of clothing without fear of fever, and so long as anyone is ignorant or foolish enough to stick to his winter dress and diet, as do, practically, all the hay-fever fiends the writer has known, he must go far enough north to give him something like winter atmospheric conditions.

The disorder under consideration is without doubt one of surfeit and skin smothering. A frugivorous and abstemious diet, plenty of air bathing, and the abandonment of all superfluous clothing—every fibre of clothing beyond a respectable covering of the body should be regarded as superfluous—under flannels worn while the sweltering wretch prays for a cold wave, what language can sufficiently emphasise such stupidity? This principle applied to the limit makes hay fever practically impossible. The same plan will speed the cure of an acute attack; proper head cooling and a fast day will do the rest.

The head is to be cooled in and in, moderately but persistently, till marked relief is felt, and repeated as often as the local fever returns. "I was wonderfully relieved in two hours, and completely cured the second day," was the report from a distant patient to whom I had wired the details of treatment. The fact of the matter is, we may all not only "lead an endurable existence" during the summer, but we may even be aggressively happy in spite of torrid waves, if we keep cool, as the artist mixed his colors, "with brains."

Charles E. Page, M.D.

867 Boylston Street, Boston, Mass.

BATHERS' "CRAMP."

Is it a Popular Fallacy?

To the Editor of the Medical Record.

Sir: We hear so much during the summer months of cases of drowning caused by so-called "cramp," that even an experienced swimmer must almost be afraid to venture beyond his depth. The newspaper article, commenting on a drowning case, generally begins with the fact that the bather was a good swimmer, but that he suddenly, when some distance from help, stopped his exertions and sank; the case is labelled "death from drowning caused by cramp."

Now, is this really so? Is the bather—an adept perhaps—liable to be struck down so quickly and without warning? If it is true, the danger from bathing in deep water is so great that one is hardly justified in running the risk.

I have not had the good fortune to analyze any case of so-called "cramp," but I have knowledge of a case of a young physician which, had it resulted fatally, would probably have been so called; as it was, the case did not end fatally and the young man lived to tell the tale: It was within two hours after eating a very hearty dinner, and after considerable exercise, that the bather, an excellent swimmer, took a plunge, feet first into the cool (70° F.) water of Hell Gate; immediately he arose to the surface, an inconceivable feeling of nausea came on, and everything before his eyes became hazy; he remembers that in a mechanical way he kept his arms and feet moving until help arrived, but during the whole procedure he was in a dazed condition—in street parlance, he had "lost his head"—the result of the nausea and possible congestion of the brain. Emesis was quickly followed by return to health. Now, this I take as an example of the danger which may befall anyone; exhaustion and cold are others; spasmodic contraction of the glottis from inhalation of water might be another; in fact, we have causes enough without calling everything "cramp;" and these causes may be reduced to a minimum by following some of the well-known hygienic rules for bathing, as (see Rohé): Never bathe within two hours after eating; never plunge in cold water feet first, but always head first, so as to avoid tendency to congestion of the brain, and never remain in the water after a feeling of chilliness supervenes.

Harvey Bashore, M.D.

West Fairview, Pa., August 23, 1894.

CONCERNING THE TABLET TRITURATE.

To the Editor of the Medical Record.

Sir: I believe there is a pretty general agreement among physicians that the tablet triturate is one of the best methods of dispensing medicines. Of the absolute reliability of these goods, as made by the best manufacturers, there can be no doubt. They are inexpensive. They are easily carried in the ordinary pocket case. The subdivision of dosage in the case of children and others, by crushing the tablet, is convenient. Not the least of the valuable features of the tablet triturate is that it enables the physician, by dispensing his own medicine, to limit, in a measure, the tendency on the part of some druggists to counter-prescribing. I believe, therefore, that one point in their manufacture is worthy of attention. I refer to stamping each tablet with a number. This has always been the custom of one large manufacturer. I learn that another leading firm is about to introduce the custom. This does not seem to me to be in the interest of the physician. I know of some instances where patients, who have had tablet triturates prescribed for them by a physician, have carefully preserved a numbered sample, and gone to a druggist with the request to "match" it; something after the manner in which ladies match ribbons at the bargain counter. The only reason I have ever seen given for numbering tablets is that of one manufacturer, that if a physician breaks a bottle, or if they become mixed in any manner, he could identify and sort out the tablets by their number. This is hardly a practical point, and breakage is little apt to occur. I believe the tablet triturate has come to stay, and I would like to see it manufactured exactly right in every particular.

Geo. W. Miles, M.D.

11 Cherry Street, Oneida, N. Y.

THE SOCIETY OF RUSSIAN PHYSICIANS.

To the Editor of the Medical Record.

Sir: In the *Novoe Vremya*, the popular Russian daily newspaper, there lately appeared an account of the proceedings of the Medical Association which was founded in memory of N. I. Pirogoff.

In connection with an interesting report on juridical medicine, it was said that the professional expert could be viewed as merely a part of the legal machinery, under direction of the judge, as a simple witness, and as a person competent to value the significance of scientific facts, and to determine, through special experiences, the anatomical changes brought about by an injury, or the accompanying psychological results ("data").

As *critique* of the foregoing, and of the whole subject, the reviewer stated that the sphere of the medico legal testifier should be enlarged; he should be empowered by law, together with the judge, to give conclusions, thus being able to show the necessary effects of the acts in question; and to keep apart all malevolent words or insinuations. Before the lawmakers lies the problem: 1. The relations of the physician to the court, in the field of medical jurisprudence. 2. The peculiarity and limits of his activity. 3. The method of action as to expert testimony; especially the bearing of all these on pedagogic instruction, which is continually changing with the advance of science.

After a discussion on disinfectants which had lasted two hours, one of the delegates summed up the matter, by saying: "The *Zemtsvo* (provincial legislature) sent me here to find out what capable experimenters would say—to learn something. I have listened long, and, I regret to say, have not obtained anything of value; I shall have to go home with empty hands." Russia is not the

only country where vain words become wearisome to the hungry mind.

The unhygienic condition of houses and villages was said to be largely due to the fact that their location is determined for the convenience of governmental administration, leaving out of view the topographical sanitary relations. The question of making legally obligatory the participation of medical men in the choice of building sites was considered by the society. The section *in re* decided that a medical inspection of new buildings was desirable. On account of extensive infectious diseases of the eyes, in villages scattered over the land, it was determined to recommend the use of preventive means at the time of birth.

The psychological division of the congress adopted a resolution for the appointment of a committee to take statistics of those showing evidence of mental infirmity and of the insane. They hoped, by this means, to relieve many now suffering in chains and hovels. Interesting demonstrations of nervous phenomena, in the perception of sensation, were given by the section devoted to psychiatrics. One physician stated that the indications of mental disease in Western Europe and in Russia were not identical.

An address was read advocating the systematic registration of sickness and death from tuberculosis, the same as in cases of infectious diseases.

From the remarks of one surgeon we learn that his recent microscopic observations, experiments, etc., make probable the parasitic origin of tumors, especially malignant ones. This tends to corroborate statements made by other investigators.

The next meeting of the society is arranged for the spring of 1896, in the heart of Old Russia, at the sacred city of Kiev.

F. B. Stephenson, M.D., U. S. N.

Boston, Mass., August 13, 1894.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE BRITISH SCIENTIFIC CONGRESS AT OXFORD—LORD SALISBURY'S ADDRESS AS PRESIDENT—THE OUTBREAK OF SMALL-POX—ARRIVAL OF A CASE OF CHOLERA ON A STEAMER—THE BACILLUS OF PLAGUE—DR. GRIFFITHS—DR. WIGLESWORTH—SIR JOSEPH FAYRER.

London, August 11, 1894.

No sooner have we finished our trip to Bristol for the British Medical Association, than we must hasten to Oxford to attend the meeting of its parent—the British Association for the Advancement of Science. This year is somewhat exceptional, as a great political leader has consented to preside, and there are rumors that his address will deal with the unsolved problems of science. The President is no other than the Marquis of Salisbury, who is Chancellor of the University of Oxford, but who appears on this occasion rather in the character of his F.R.S. It is known well enough to a few that his Lordship's studies have been by no means confined to the ancient learning or dimmed by his ardor in politics, but have extended so far in scientific directions as to entitle him to a high place among practical scientists. In some points his researches have been greatly appreciated, but no little curiosity was felt and expressed as to what he would say in his presidential address. Let me say at once that this address would have been no disappointment had it come from one of the masters whose whole life had been devoted to science, and when we remember the other directions in which Lord Salisbury's mind has been engaged, it is very remarkable. He showed himself at home in the theories of the chemical elements, in the discoveries of the spectroscope, and the problems of the ether. From these unsolved enigmas he passed to the riddle of life and sketched with a master-hand the controversy that has raged since Darwin's "Origin of Species" appeared. The effect of this work was shown and its proved results admitted, while the differences of view existing were also stated. The differences between the mathematicians and biologists were touched upon, but his Lordship said he would not get into the line of fire between them by intervening, and until the differences are adjusted laymen are justified in giving a verdict of "not proven" on the tremendous issues raised by the most advanced Darwinians. Then came a caveat against the "great danger scientific research is running at the present time, the acceptance of mere conjecture in the name and place of knowledge, in preference to making frankly the admission that no certain knowledge can be attained." This point was illustrated by a reference to Professor Weismann's dictum, that we must accept natural selection because, if not, we must fall back on the agency of design, which the professor seems to look upon as an inadmissible conclusion, or even a heresy. But Lord Salisbury's statement will not easily be met by Professor Weismann, especially as he reinforced his logic by falling back on the judgment of Lord Kelvin, "the greatest living master of natural science among us," and quoting the peroration of that master's address from the same chair, more than twenty years ago, these significant words:

"I have always felt that the hypothesis of natural selection does not contain the true theory of evolution, if evolution there has been in biology. . . . I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoölogical speculations. Overpoweringly strong proofs of intelligent and benevolent design lie around us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back to us with irresistible force, showing to us through nature the influence of a free-will, and teaching us that all living things depend on one everlasting Creator and Ruler."

Small-pox is still with us. The outbreak at St. John's Wood, which I reported, is the most serious we have had since 1885, but it appears to have been conquered by the determined and active intervention of the sanitary authorities. But for the energy displayed, we might have found it extending to the whole metropolis.

A steamer arrived off Gravesend, from St. Petersburg, bringing cholera, one of the crew having died on the short voyage. The vessel was visited at once by the medical officer of health, and one or two suspicious cases removed for observation. The bacteriological diagnosis is cholera. We may probably have other importations, but if all are as carefully segregated we may perhaps escape an epidemic.

The bacillus of the bubonic plague has been sent to London, and was exhibited at Bristol also, where a very fine collection of cultivations of bacteria was shown by the Institute of Preventive Medicine; all sorts of microorganisms were exhibited growing on various media, and would give the opportunity of acquiring or extending knowledge to most people, could time be afforded for serious study. Of course, in a crowd at such an exhibition this is impracticable.

Dr. Griffiths, of Swansea, to whose cruel case of slander I have alluded in previous letters, has received £500 from the fund started in his defence, with an illuminated address of sympathy.

The medical superintendent of Rainhill Asylum, Dr. Wiglesworth, has been stabbed by one of the lunatics who had concealed a knife in his sleeve. The wound is serious, and the doctor not yet out of danger.

Sir Joseph Fayrer is about to retire from the service in which he has done such admirable work.

Double Pay for Twins.—A man in Ohio was arrested not long ago at the instance of a woman who claimed that he was the father of her unborn child. He was released on payment of $300. But when the time came it was found that there were twins, and the poor man was arrested again, and the penalty for his misdoing was promptly doubled by a sympathetic jury.

New Instruments.

A LID ELEVATOR FOR CATARACT OPERATION.

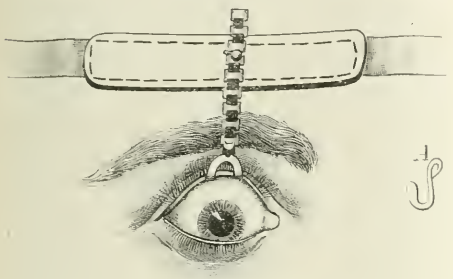
By EDWARD SWASEY, M.D.,

WORCESTER, MASS.

OCULIST AND AURIST TO WORCESTER CITY HOSPITAL.

THE most troublesome instrument that is used about the eye in removal of cataract, and in all operations in which the globe is opened, is undoubtedly the speculum. And moreover, it is always a possible means of injury to the eye, for the patient may at any moment forcibly press it down upon the globe by the strong action of the orbicularis muscle, and if the corneal section has been completed, he will almost surely force the lens out prematurely, and not infrequently some of the vitreous will follow it.

Because of this danger, some of our best operators carefully remove the speculum as soon as the lens capsule



has been opened, and thus avoid this possible dangerous compression of the incised globe. Others do away with the speculum entirely, and elevate the upper lid by means of the lid elevator, held by an assistant. But the arm of an assistant is unavoidably more or less in the operator's way, and must be worked around, even if a trained and trustworthy hand of an assistant could always be at command to hold the elevator. But an instrument which securely holds the lid open, and has its point of anchorage outside the lids, is much freer from the danger of this compression of the eye than is the speculum, which simply rests within the lids. And at best, the speculum is an awkward instrument to unlock and remove from under the two lids, at a time when the utmost gentleness is necessary in every step of the operation. At least I have found it so, and seeing the simplicity of the lid elevator, I have tried to make use of it, and yet be free from an assistant. The little device shown in these drawings accomplishes the object. The lid-hook of the elevator is carved into the shape shown at *A*, and it then holds securely under the lid; the ordinary form is at once tilted from under the lid at the first attempt to close the lid. This is attached by a flat-linked chain to a small, blunt, shallow hook on a forehead piece which is securely held in place by the ordinary head-band. The chain is two and a half inches in length, and has eleven open links, which admit of fine adjustment of the lid elevation; the hook gives an additional length of half an inch. The shallow hook allows the quick and easy removal of the chain without forcibly drawing on the lid, and once detached the lid hook is as readily slipped from under the lid as any elevator. The flat links adjust themselves to any angles that are found from the lid piece to the head-band, and the whole field of view is unobstructed for the operator. The patient cannot even begin to close his eye with this in place.

The chief objections I find to the Pyle instrument[1] are that it projects forward from the brow so far that it seriously obstructs the operator's view, and the adjustments are so many, too much mechanism is required. I have made use of the instrument here described in cataract operations, and it certainly has advantages over the ordinary speculum: it is so quickly and easily removed. George Tiemann & Co., of New York, made the instrument for me.

[1] MEDICAL RECORD, August 1, 1891, p. 139.

A POCKET PELVIMETER.

By HERMAN L. COLLYER, M.D.,

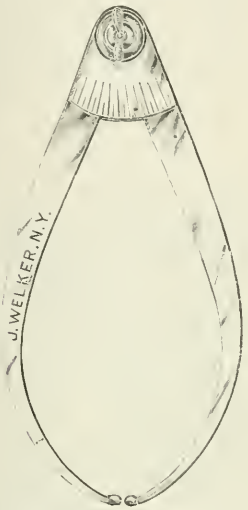
NEW YORK.

GYNECOLOGIST TO THE WEST SIDE GERMAN CLINIC, ASSISTANT GYNECOLOGIST TO THE FRENCH HOSPITAL, ETC.

THE measurements of the female pelvis are so great a necessity in obstetrics that I feel a simply constructed, inexpensive instrument, within the reach of every physician, would be very acceptable, and would tend to encourage pelvimetry in the profession generally.

It is a frequent occurrence that a contracted pelvis is unrecognized until the labor has become tedious, at a time when symphyseotomy is made difficult by the delay.

In my first case of elective symphyseotomy, performed successfully June 5, 1894, I was led to devise some accurate, inexpensive pelvimeter, possessing all the advantages of the expensive instruments, and correcting some of their disadvantages. As the idea is purely original, I may say, I hope by the insertion of this article my read-



ers will derive benefit from my endeavors and be encouraged to practise pelvimetry more extensively.

The instrument is twelve inches long, elliptical in shape, capable of measuring to the extent of fourteen inches, with a pivot hinge and thumb-screw attached to one end. At this end there is a semicircular plate, marked legibly with the metric system on the one side, and the English system of measurement on the other, in a convenient position to be read easily. The advantage of having the two systems together is very great, as it admits of ready comparison and reference.

Through the kindness of Mr. J. Welker, instrument-maker, of this city, I am able to present to the profession a portable and inexpensive pelvimeter, which will, I think, commend itself to everyone.

109 EAST FIFTY-FOURTH STREET.

Salines operate in three or four hours. Croton-oil in one or two hours. Jalap, gamboge, and senna in three or four hours. Rhubarb and castor-oil in from four to six hours. Aloes and mandrake in from ten to fourteen hours.—*Louisville Medical Monthly.*

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending August 25, 1894.

	Cases.	Deaths.
Tuberculosis	86	115
Typhoid fever	26	7
Scarlet fever	22	1
Cerebro-spinal meningitis	0	2
Measles	11	2
Diphtheria	113	36
Small-pox	7	0

To Increase the Birth-rate of France.—Stringent laws have recently been enacted by the French Government, which, despairing of obtaining any increase in the birth-rate of the land, is endeavoring to save the few children that are born. One of these regulations forbids, under a severe penalty, anyone to give infants under one year any form of solid food, unless such be ordered by a written prescription, signed by a legally qualified medical man. Other regulations are equally restricting, and, as the French have a knack of enforcing their enactments, down to the most trifling ones, as American visitors to Paris often find to their cost, it is probable that many childish lives will be saved. One could wish, on seeing an East-Side tenement mother feeding her few months' old baby with a peach or banana bought from the curb fruit-stall, after half a day's exposure to the August sun, that the municipality of New York would copy a few of these French regulations. It would vastly lessen the work of the dispensaries and visiting tenement physicians.

The Treatment of Diphtheria with Immunizing Serum.—Professors Ehrlich, Kossel, and Dr. Wasserman, in Berlin, have published a paper on the application of curing serum, as invented by Professor Behring, assistant of Professor Koch. Behring had undertaken to give an immunity from the diphtheritic poison, and after that to get a serum from the blood of those animals, by which he hoped to protect individuals of the human race against the results of diphtheria, as well as to cure the disease when already developed in an individual. Ehrlich, Kossel, and Wasserman have followed Behring in his experiments. They always had in view to use the results of their experiments for curative purposes. They experimented on goats. We will say nothing of the technical dates for giving the serum. Two hundred and twenty patients with diphtheria were treated with the serum. Of these there were cured 168, or 76.4 per cent.; 52 died. Tracheotomy was performed in 67 cases, of which 30 died; the rest recovered. But a true insight of the curing effects of the injections is gathered only by grouping the number of the diseased people by the days after the infection on which the treatment was begun:

Day after beginning of treatment.	Treated.	Cured.	Died.	Percentage of cures.
First day	6	6	0	100
Second day	66 (9 tracheotomies.)	64 (7 tracheotomies.)	2 (2 tracheotomies.)	97
Third day	29 (8 tracheotomies.)	25 (7 tracheotomies.)	4 (1 tracheotomy.)	86
Fourth day	33 (14 tracheotomies.)	30 (10 tracheotomies.)	9 (4 tracheotomies.)	77
Fifth day	23 (10 tracheotomies.)	13 (4 tracheotomies.)	10 (6 tracheotomies.)	56.5

It is to be seen by this table of dates that the safety of the serum treatment depends essentially upon the date on which the treatment of the children is begun, and that on the first day results were had never seen before. Of 72 children received at the hospital during the first two days of the disease, there were only 2 deaths; of 72 cases treated *without* serum after statistics reaching over twenty five years, there were 25 deaths, or 34.7 per cent.

The above-named experimenters give the following points of view for the treatment with their serum of those children sick of diphtheria: 1. *The fate of the children depends upon the treatment during the first three days of the sickness.* Therefore the serum should be injected as soon as possible after the beginning of the disease. 2. As there must be a surplus of antitoxine in the sick body, the dose of commencement should be, in light cases, at least 200 unities of immunization. In cases of gravity and in those tracheotomized, 400 unities were needed. The treatment with serum should be continued some time after ceasing of rise of temperature and of the local inflammation. The total amount of dispensed serum may reach in a single case (in correspondence with the gravity of the symptoms) 500, 1,000, 1,500 unities of immunization.—Berlin Correspondent *Journal of American Medical Association.*

A Revival of Hindu Medicine.—The educated natives of India intermittently advocate, through the native press, the resuscitation of indigenous and time-honored methods of treating disease which have fallen into disrepute and disuse. The merits of ancient drugs and of primitive practices and practitioners are on such occasions vaunted as being better in themselves and better adapted to the people and circumstances of Hindustan than exotic systems and medicines. It appears that dispensaries have been established in the native states of Travancore and Mysore, for the purpose of giving the natives of these territories the benefits of Hindu medicines, which are considered more congenial, cheap, and efficacious than foreign medicines. Foreign surgery is allowed to be infinitely superior to native, and no attempt is made to compete with that. It is recognized that native doctors are, with few exceptions, ignorant and uneducated, and it is proposed to teach them "chemistry, physiology, hygiene, and other kindred subjects."

Worse than "Pidgin."—Dr. W. P. Noble, of Pao Ting Foo, China, sends us the following letter, addressed to him by a native in government employ in that city: "I am deject indeed for I got a kind of measles and cannot come to your Hospital because on duty this noon; I not know whether you can come to my office or not, I hope you come and let you know what measles it is. If you allow me well much hosanna recieve from you. I cannot conceal my sickness from you. When I make water the water come to the end and stop there until a little while, then meander out in that time of which I speak that is very painful. I hope you excuse me at once.

"Yours respectifully,
"P. S. W."

The Difference.—When a lawyer defends a man for his life, and by some technicality or shrewdness he gains his case that lawyer is often spoken of as "that man who saved my life." When a person is stricken down, we will say with strangulated hernia, just as sure death as hanging unless relieved, he sends for the physician, who understands this technicality of nature, and relieves him, saves him not from the gallows, but death. He does not say "that physician saved my life," but "through the providence of God I escaped death."—*Charlotte Medical Journal.*

Lively Apothecaries and Deadly Consequences.—In Stendal, not long since, the police forcibly closed a drug-store where they found the proprietor away, and the two clerks intoxicated. Before their condition was discovered they had compounded a number of prescriptions, mixing up various drugs without any regard to directions or dosage.

The Plague in London in 1664, with which the present epidemic in China is believed to be identical, caused 69,000 deaths out of a total population of 460,000.

SOME CONSIDERATIONS ON DIFFERENT TYPES OF EXUDATIVE INFLAMMATION.*

A STUDY BASED ON BACTERIAL EXAMINATIONS FROM ONE HUNDRED AND THIRTY-FIVE SURGICAL CASES.

BY CHARLES N. DOWD, M.D.,

NEW YORK.

ASSISTANT SURGEON TO THE NEW YORK CANCER HOSPITAL.

IT is evident that all inflammations which call for surgical treatment are not alike: some spread in the tissues rapidly and persistently; some remain localized, but cause necrosis of the involved tissues; others neither spread far nor cause severe injury to the affected parts. Again, some cause profound constitutional disturbance with very slight local effect, while others produce extensive local disturbance with slight constitutional effect. Some cause discharges of greenish, odorous pus, so profuse as to quickly saturate bulky dressings; others give only a small amount of thin, sero purulent effusion. These differences are largely due to the particular species of bacteria which cause the inflammation, and to variations in virulence which bacteria of the same species may show, although the site of the infection and the condition of the patient may have much influence.

In the effort to investigate the subject, we have in the past year made bacterial studies from 135 cases which were seen in the Vanderbilt Clinic, the New York Cancer Hospital, and in two instances in the practice of other surgeons who gave us the opportunity of studying cases of pyæmia.

Those seen at the Vanderbilt Clinic were ambulant cases; a large number of them had acute forms of suppurative inflammation, which had originated from small wounds or had extended into the subcutaneous tissues, so as to cause cellulitis of greater or less extent. Some had fresh wounds with little inflammation about them; some granulating and healing wounds, and some furuncles and abscesses of a less acute type.

Those seen at the Cancer Hospital were operative cases. In some of them ulcerating growths were examined before operation; in others wound discharges and stitches were examined after operation.

The cases may be clinically grouped as follows:

	Cases.
Cellulitis	51
Fresh infected wounds	17
Granulating wounds	18
Healing wounds (stitches)	5
Furuncles	7
Abscesses	37

The material for study was obtained on the sterile swabs which have been described by Dr. Park.[1] They are made by twisting bits of cotton on the ends of pieces of stiff wire. They were inserted into the depths of the wounds so as to avoid surface contamination, and were immediately streaked across agar Petri's plates. The plates were then put into the thermostat and the growths studied in the ordinary way with the microscope, and by further gelatine and beef-tea cultures; also by animal inoculations in certain instances. In a large proportion of the cases morphological studies of cover-glass preparations of the pus were also made.

The bacterial work was done, with the collaboration of Dr. William H. Park, in the Bacterial Laboratory of the College of Physicians of New York City, or in connection with that laboratory.

The following table indicates in a diagrammatic way the results of the examinations:

	Cellulitis. 51 Cases.	Infected Fresh Wounds. 17 Cases.	Old Granulating Wounds. 18 Cases.	Healing Wounds, Stitches. 5 Cases.	Furuncles. 7 Cases.	Abscesses. 37 Cases.
Streptococcus pyogenes alone	9	3	..	..	..	8
Streptococcus pyogenes predominant	23	3	..	..	..	8
Streptococcus pyogenes relatively few	3	1	6	..	..	1
Staph. pyogenes aureus alone	11	1	1	1	7	6
Staph. pyogenes aureus predominant	8	2	..	..	..	1
Staph. pyogenes aureus relatively few	13	3	..	..	..	2
Staph. pyogenes or epidermis albus alone	1	4	2	4	..	2
Staph. pyogenes or epidermis albus predominant	..	1	..	..	..	..
Staph. pyogenes or epidermis albus relatively few	10	5	3	..	..	6
Staph. cereus albus	3	1	2	..	..	1
Staph. citreus	1	..	2	..	..	1
No growths on agar	..	..	..	..	..	11
Very few growths on agar	..	..	3	..	..	3
Bacillus pyocyanus	..	..	1	..	..	3
Bacillus coli communi	..	..	..	..	..	3
Overgrown	4	..	2	..	.	1
Few undetermined colonies	12	2	5	..	..	5

In those instances in which streptococcus pyogenes are recorded "predominant," the associated forms were mostly staphylococci, and in those instances in which staphylococci are recorded predominant, the associated forms were mostly streptococci.

Analysis of the Tabulated Results.—From all the cases in which there was acute inflammation accompanied by severe constitutional symptoms, abundant cultures of streptococcus pyogenes or of staphylococcus pyogenes aureus were obtained; frequently both existed in the same case. These two organisms were by far the most important ones found, and as there were well-marked peculiarities in many of the inflammations which they caused, it may be well to give a somewhat detailed account of the conditions in which they occurred. To this we add a description of the conditions in which certain other forms were found.

Streptococcus Pyogenes.—Among the fifty one cases of cellulitis studied there were eight which showed a persistent tendency to spreading inflammation with undermining of the tissues, which continued in spite of free incision, careful packing, and moist dressing, and in all of these streptococci were found.

As an example of this group we may note one in which an inflammation which involved the entire forearm spread rapidly from a small butcher-knife cut on the back of the hand; free incisions were promptly made, the wounds were carefully packed with gauze, and moist antiseptic dressings were applied, much of the time daily. Still the inflammation continued for more than three months, the fascia sloughed away in large pieces, and there was a continual undermining of the tissues, with the formation of pus pockets even when healing was progressing at the margins of the incisions; and finally the patient was left with a stiffened hand and wrist. Repeated bacterial examinations of the pus showed only streptococci pyogenes in the depths of the wound, while a few staphylococci were also twice found on the surface.

* Read before the Surgical Section of the New York Academy of Medicine, March 12, 1894.

The two cases of pyæmia illustrated the same characteristic spreading, undermining streptococcus inflammation. In both, the streptococcus and staphylococcus pyogenes aureus were found in the original wounds, while in the metastatic abscesses the streptococci were found without the staphylococcus pyogenes aureus. In the first a phlegmon of the arm appeared a week after the operation, and progressed until it involved the entire arm and hand; a little later there was a similar phlegmon in the back; there was also inflammation in several of the joints. Incisions were made at different times in five separate places in the back and arm, and pure cultures of streptococci were obtained from the pus found at each incision; the abscesses were persistent; the one in the back remained open six months, until the patient's death. In the other case the metastatic abscesses were of a similar character, but less extensive.

This spreading, undermining characteristic of streptococcus inflammation has been often described and is well established. Inflammations of this variety were the most virulent which we had to deal with; no available treatment seemed sufficient to promptly limit the growth of the streptococci in the tissues; cultures could be obtained from the walls of the pockets after washing them with a 1 to 1,000 solution of bichloride of mercury, and free and early incision and packing did not prevent the undermining process of the inflammation.

There was a group of cases closely allied to these in which streptococci were always found; cases which represent an intermediary phase between typical cellulitis and typical erysipelas. In the skin there was induration and an inflammation somewhat less distinctly marginated than in typical erysipelas; in the subcutaneous tissue a little pus was found.

The condition is illustrated by the following case: A healthy man scratched his hand on a dry-goods box one week before admission to the clinic. Three days later he began to have pain on the anterior surface of the arm just above the elbow, and at the same time he had a chill. On admission there was an indurated area on the anterior surface of the arm about 5 x 6 inches in extent. The skin was œdematous and red. On the outer side the redness was marginated and extended half way down the forearm. On the inner side it was not marginated. Temperature, 100° F.; pulse, 80. There was hardly any axillary tenderness or enlargement of lymph nodes. There was no distinct fluctuation, but an aspirating needle inserted just above the elbow withdrew pus from which a pure culture of streptococcus was obtained.

Most surgeons would not call this erysipelas, but in the seven cases which were of this general type we were much puzzled to know whether we were dealing with erysipelas or cellulitis, and in one instance a patient who had diffuse induration and inflammation about an infected wound, which seemed far less like erysipelas than the above, returned on the second day with typical erysipelas so well marked that no one would question the diagnosis.

Cases like these make a chain of union between erysipelas and cellulitis, which would lead us to believe that there is no absolute and fundamental distinction between the two phases of inflammation. This is practically the same ground which bacteriologists have taken.

Passet,[2] Rosenbach,[3] Prudden,[4] Biondi,[5] Fraenkel,[6] Roger,[7] Welch,[8] Baumgarten,[9] Kirchner,[10] Crookshank,[11] and many others, have studied the relationship between the streptococcus pyogenes and streptococcus erysipelatis, and the weight of authority indicates that there are no constant differences between them, and that the variations are no greater than are frequently seen in individuals of the same species.

It is, however, a point of considerable importance, that infection from one type of streptococcus inflammation is likely to reproduce the same type. Infection from erysipelas is likely to cause erysipelas, as all surgeons know and as Fehleisen[12] proved by a series of inoculations. Just how likely it is to produce other forms of inflammation we do not know, but Coley[13] in making 120 inoculations to produce erysipelas, only caused two abscesses, and these he thought were due to contaminations of staphylococci. Hajek[14] found that the original type of streptococcus inflammation was usually reproduced in inoculated animals.

This close alliance between erysipelas and phlegmonous inflammation is a matter of much practical importance. We fear erysipelas and avoid all contact with it when engaged in operative work. The man who would care for a case of erysipelas and then do an operation or attend an obstetric case, would be considered very culpable. Yet the same precautions are not taken in regard to other kinds of streptococcus inflammation. A suppurating wound in which the pus teems with streptococci is certainly more likely to contaminate the surgeon's hands than a case of erysipelas is, and this contamination may well be followed by suppuration, phlegmonous inflammation, or perhaps by pyæmia, in the patient whom he operates upon soon afterward. But such an occurrence would be considered an unavoidable wound accident, while the erysipelas, which is more characteristic, would be traced to its true source. The danger of transmitting erysipelas has long been guarded against, because the infecting case and the infected case so closely resemble each other. But when we remember that in any case of streptococcus inflammation we are dealing with a germ which is not to be distinguished from that which causes erysipelas, and furthermore, that it is often capable of causing an inflammation more virulent than erysipelas, it is obvious that the greatest care is necessary to avoid transmitting infection.

Beside these groups of cases, streptococci were frequently found where there was nothing particularly characteristic. They were present in 65 out of the 135 cases examined. They were found in almost all the cases of severe inflammation, but they were also present in many of the mild ones, and they did not always cause a spreading inflammation. In one instance they were found in almost pure culture in a finger bleb which seemed hardly more than a large blister, and which had existed for several days without showing acute inflammation. Whether these differences depend on the varieties of streptococci and their variations in virulence on the constitution of the patient, or on the thoroughness of the inoculation, one can hardly state. Probably all these factors have their influence. The condition finds its parallel in other forms of infection; for example, the bacillus typhosus sometimes causes only a slight fever and sometimes causes death, and Loeffler's bacillus sometimes causes a slight sore throat, and sometimes a diphtheria which is quickly fatal.

Variations in the growth of the streptococci were noticeable. Some grew in long chains and some in short ones; and the colonies differed in their general appearance microscopically and macroscopically, also in the quality of imparting cloudiness to the beef-tea in which they grew. In view of the work of v. Lingelsheim[15] on the subject, we noted the relationship between the length of the chains and the virulence of the infection, and found that in certain instances the short- as well as the long-chained varieties were virulent.

Staphylococcus Pyogenes Aureus.—In the entire series of 135 cases it was found in pure cultures 26 times, and in no one of these cases was there a spreading inflammation. The cases of cellulitis of the hand illustrate this well—there were 11 of them in which staphylococcus pyogenes aureus alone was found, and in no instance did the inflammation extend upward so as to make incision above the wrist necessary; while in the 23 cases in which streptococci were the predominant bacteria, there were 5 in which incision was necessary at some point above the wrist, and streptococci were found in these incisions.

A boil illustrates in a limited way the type of inflammation which these staphylococci cause: a severe inflammation producing necrosis of tissue and giving a comparatively severe constitutional reaction, but not

spreading widely by direct extension. Seven boils were examined, and all had them in pure culture.

The following case also illustrates this kind of inflammation: The patient sustained a compound fracture of the middle phalanx of the ring-finger, which was followed by inflammation in the soft parts and in the bones. Three weeks after the injury amputation was done through the proximal phalanx, in the hope of preserving a part of the finger, but suppuration continued in the soft parts of this stump for more than two months. The inflammation, however, never extended above the finger. It was severe enough to destroy the bone before the amputation and to keep up a most tedious suppuration after it, but it did not show any tendency to extend upward.

Cultures were made from this wound at six different times, and unmixed growths of staphylococcus pyogenes aureus were obtained in all instances excepting one; in that one a contamination—presumably saprophytic—was also found. We are well aware that these staphylococci may enter the blood current and cause a fatal pyæmia, and that they have been found in many cases of osteomyelitis,[16] but in this series of cases they remained localized even when the streptococci which accompanied them in the original wound caused metastatic abscesses.

These staphylococci have frequently been considered more important than the streptococci, but the recent bacterial studies indicate that the streptococci are the more important and the more common; in this series of cases they were certainly so. It is to be remembered that the staphylococci grow in large thick colonies on the agar, while the streptococci grow in small thin colonies; hence it is possible that in some cases which have been reported the streptococci may have been covered by the large colonies of staphylococci. One of the cases here recorded shows how easily such an error could be made. An infected wound was surrounded by an inflammation which had the appearance of a streptococcus inflammation, but the first culture showed abundant staphylococci and very few streptococci; a second culture, however, taken on another day from an undermining part of the wound, showed streptococci almost alone. It would obviously have been an error to conclude from the first examination that this was an instance of staphylococcus inflammation. The difficulties of finding the colonies of streptococci are greater where roll tubes are used than with Petri's plates.

Staphylococcus pyogenes aureus was also found in certain instances in mild inflammations in which there was nothing particularly characteristic.

The inflammations caused by staphylococcus pyogenes aureus were much more easily controlled than those caused by streptococci. Moderate-sized incisions with gauze packing and moist, mild antiseptic dressing, were usually quickly efficient.

Staphylococcus Pyogenes Albus—Staphylococcus Epidermis Albus.—Besides those mild cases already referred to there was a group of cases which showed a mild form of inflammation and gave cultures of white staphylococci, or in certain instances of lemon-colored staphylococci. One could not say that in all mild cases only these staphylococci were to be found, but where they alone were present the inflammation was always of a mild type.

The white staphylococci were found in pure culture in thirteen cases. Only one of these was a case of cellulitis, and that was sufficiently interesting to merit particular attention. The point of infection was apparently a palmar blister at the base of the middle-finger; the inflammation extended into the palm and between the fingers, and caused considerable swelling and superficial fluctuation. There was, however, little pain or constitutional disturbance, and on incision the pus was found to lie mostly just below the epidermis, which was raised from the true skin. After incision the inflammation subsided very quickly. Bacterial examinations were made four different times, and white staphylococci were found in pure culture each time.

This was manifestly a very mild form of inflammation, and the other conditions in which the white staphylococci were found indicated an equally mild action. Five times stitches were examined from wounds which healed aseptically or with only slight moisture, and from four of them pure cultures of the white staphylococci were obtained. They were also found alone from a needle used in the skin of a clean wound and from a clean drainage opening. Once they were found in pure culture in a blood clot under which a resected finger-joint had healed; twice in old sinuses which led to dead bone; and they were almost always found in superficial granulating wounds.

Hence we see that in all instances they were so found as to indicate that they had a very mild infective power. They were found in association with other bacteria very frequently in wounds which had been opened. In these instances it is believed that they were carried in from the skin, and that usually they were not the cause of the original inflammation.

In 1884–85, when the classical articles of Rosenbach[17] and Passet[18] appeared, describing the pyogenic cocci which they found in acute inflammations, the staphylococcus pyogenes albus was believed to be of practically the same pyogenic power as the staphylococcus pyogenes aureus with which it was usually associated. This belief was based largely on animal inoculations.

In the only case, however, in which Rosenbach found the albus in pure culture, the inflammation was of so mild a type as to have been clinically considered gonorrhœal rheumatism of the knee.

Passet did not record the clinical histories of his cases. Since that time numerous observations have been recorded which indicate that they are usually of very mild pyogenic power.

Welch[8] has made a very extensive study of the subject, and has found white staphylococci regularly present in the skin, and frequently present at the margin of healing wounds. He found that they usually did not interfere with the healing of wounds if the tissues were in good condition. Although they might occasion stitch abscesses or a little suppuration along drainage openings, or where the tissues were strangulated, they might cause severe inflammation. Their pyogenic power was so slight that he considered the term staphylococcus epidermis albus preferable to staphylococcus pyogenes albus.

Whether staphylococcus epidermis albus and staphylococcus pyogenes albus are the same organism, is not entirely settled, but Welch's suggestion that the former may be a modified form of the latter, certainly meets the requirements of the present stage of the investigation In this series of cases no effort has been made to separate them. Those colonies which remained white on the agar for several days, which were morphologically like the pyogenic staphylococci, and which fluidified gelatine, were recorded simply as white staphylococci.

Among the other observers who have found white staphylococci of mild infective power, we may mention the following:

Grisky and Robb[19] found them in nineteen out of forty-five laparotomy wounds, and they did not prevent prompt healing.

Bossowski[20] found them in wounds which were treated aseptically, but they did not interfere with the healing in any marked degree.

Lanz and Flach,[21] in examining wound discharges, found that where staphylococci pyogenes aurii were present there was severe suppuration in all the cases but one, and that where the white staphylococci alone were present the wounds regularly healed well.

Many cases of serous effusion have been reported which contained the white staphylococci. Levy[22] produced suppuration in rabbits in two instances from white staphylococci so obtained. For further literature on the subject, the reader is referred to Jordan[16] and Sternberg.[23]

These observations indicate that the white staphylococci usually cause a much milder type of inflammation

than the golden ones. We say usually, because we must recognize the variations in virulence which are shown by all the forms of bacteria which we are studying.

The question is one of much practical importance: here is a form of suppuration which need not be feared as the severer forms are; for instance, it is possible for a wound to heal well under a blood clot when these cocci alone are present. It seems reasonable that granulating wounds which have only this form of infection should have their edges brought together and only a very small allowance for drainage made, and that all wounds which have only this form of infection should be treated with little fear of serious inflammation—*staphylococcus pyogenes citreus*.

In four instances, staphylococci were found which appeared identical with the white staphylococci in all respects, excepting that after eight or ten days they turned to a lemon color on agar.

They were found in a superficial abscess and in healing wounds, and produced very slight constitutional reaction. They fluidified gelatine slowly, and when injected under rabbits' skins in beef-tea cultures, they produced only a little induration and congestion.

They are much slower in turning to a lemon color than the staphylococci pyogenes citrei described in the text-books.

Cases from which no Bacterial Growths Could be Obtained on Agar.—There was a group of eleven cases from which the pus gave no growths on agar. They were abscesses presumably tubercular, or buboes, and the courses which they ran bear decidedly on the question of injection versus incision for these conditions. A case of large tubercular abscess shows the point of issue. It was so situated as to make the diagnosis obscure until incision was made. The incision liberated a large amount of pus which was sterile, in the sense that no bacteria grew from it on agar. A few days later, however, the pus in the wound contained streptococci and the symptoms changed accordingly. There was the febrile reaction and the constitutional symptoms which accompany the streptococcus infection. It had been impossible to keep infection from the open discharging wound, and the patient had suffered accordingly. When the diagnosis can be made in such cases, it is manifestly wiser not to open the abscess in such a way as to allow the entrance of the streptococci.

Some of the tubercular cervical abscesses showed a similar course. There is one under observation at the time of writing, which was incised and curetted three and a half months ago, which has discharged thin pus and formed unhealthy granulations ever since and is still open; while others of a similar nature which were aspirated, and injected with a ten per cent. mixture of iodoform in vaseline, show only a little hardening at the site of the abscess.

Buboes show a similar condition. They frequently remain open and suppurate for many weeks when they are incised and curetted; yet we have seen two heal promptly and well under aspiration and injection of iodoform and vaseline, and Otis[24] has reported many such cases.

The reported cases of pyosalpinx in which the pus is found to be sterile, illustrate the same condition of pus without infective power, and such are not to be treated as those cases are where there is acute purulent inflammation.

It is possible that some of the cases examined had abscesses which had become sterile through the dying out of the bacteria which had caused the original suppuration. Further studies are needed on this point. There certainly were many cases which were almost sterile, in which only very a few bacteria grew along a heavy streak of pus; perhaps a dozen colonies where hundreds of colonies would be expected if the process had been an acute one; hence it is evident that bacteria inclosed in an abscess may show a tendency to die out.

Cases in which the Bacteria which Caused the Original Inflammation were Replaced by Others.—Some of the cases already referred to, in which the white staphylococci were found, belong to this group, since they were evidently carried into the wounds from the skin. In other cases, particularly old ulcers, the bacteria of decomposition were found in such numbers as to cover all other forms on the agar. In others, the bacillus pyocyaneus was found. In a recent monograph, Schimmelbusch,[25] called attention to some interesting facts concerning these bacilli.

1. They are regular inhabitants of the skin, particularly in the axilla, the groin, and the anal furrow.
2. They are capable of infecting wounds which occur where they exist.
3. They usually cause profuse suppuration with little constitutional disturbance.

These characteristics were shown in the four cases in which we found these bacilli. In two of them axillary abscesses which at first contained streptococci, afterward had the bacilli pyocyanii; a third case showed the growth from a mastoid abscess; the plain gauze dressing in this instance became bright green over a considerable area; in the fourth case the patient had a severe burn of the hand, the discharge in this case was so profuse as to quickly penetrate a gauze dressing an inch or two in thickness; yet when some of the metacarpal bones were removed the wounds healed well, the patient seemed to suffer only from the exhausting effect of so much pus production.

Healing occurred in all the cases within a resonably short time, and in all suppuration was free but the constitutional symptoms were slight.

Bacillus Coli Communis.—It may be mentioned that in three cases of ischeo-rectal abscesses the bacillus coli communis was fonnd. Neither of the cases were particularly virulent. In both the bacillus grew in pure culture on the agar plates. No particular importance is ascribed to these cases as their number is so small.

Summary.—In review we may say that in the ordinary cases which we have seen, at least five fairly distinct types of inflammation have been recognized.

1. A severe form of inflammation which showed a tendency to spread through the tissues, and which was caused by the streptococcus pyogenes.
2. A severe form of inflammation, more localized than the above, caused by the staphylococcus pyogenes aureus.
3. A mild form of inflammation, caused by staphylococcus pyogenes or epidermis albus, or in certain instances by the staphylococcus pyogenes citreus.
4. Slowly progressing inflammation, in which the ordinary pyogenic cocci were not found; such as cold abscesses and buboes.
5. Inflammation in which the bacteria which caused the original infection had been replaced by other bacteria; particularly by the bacillus pyocyaneus and the bacteria of decomposition.

The inflammations of these groups call for different treatment. The acute streptococcus inflammations should have early and extensive incisions, packing of the wounds, and continual moist dressing. The staphylococcus pyogenes aureus inflammations call for similar, but somewhat less vigorous, treatment.

The inflammations caused by the white and lemon-colored staphylococci need only small incision, and wounds which contain only these cocci are favorable ones for secondary suture.

Abscesses which contain no pyogenic cocci (such as tubercular abscess and buboes) should not be so opened and dressed as to allow the entrance of these cocci; aspiration and injection of a ten-per-cent mixture of iodoform in vaseline is frequently good treatment for them.

Cleansing of the wounds and the application of non-irritating absorbent dressings, are the means to be used against the bacilli pyocyanii and the bacteria of decomposition.

In a large proportion of cases the bacterial examination can be made in time to guide the treatment; in very many cases, however, the characteristics of the inflamma-

tions are sufficiently well marked to make this unnecessary.

It is to be remembered that bacteria of the same species show marked variations in virulence, and that those of slight virulence do not always show plainly the peculiarities which characterize the virulent ones.

METHODS OF ESTIMATING THE HEIGHT FROM PARTS OF THE SKELETON.[1]

BY THOMAS DWIGHT, M.D., LL.D.,

NAHANT, MASS.

PARKMAN PROFESSOR OF ANATOMY AT HARVARD UNIVERSITY.

THIS is an anatomical problem which of late has been coming into more and more prominent notice, and is applied both to the determination of the heights of extinct tribes and nations of which the skeletons have been found, and also to the identification of individuals. It is evident that the process is not necessarily the same for these two purposes. In the case of races individual peculiarities are of little account, and reliance may be placed upon averages. This cannot be done when the question is of the identification of a certain skeleton.

The purpose of this paper is chiefly to discuss the methods to be used for single cases, more particularly in medico-legal practice.

The process of estimating the height from the more or less detached pieces of the skeleton may be done according to either of two very different plans, which under certain circumstances may be profitably combined. These plans are the anatomical and the mathematical. The former consists simply in putting the bones together, in reproducing the curves of the spine, in making due allowance for the soft parts, and in measuring the height.

In an essay on the "Identification of the Human Skeleton," published in 1878, I gave certain rules for this process. Since then I have endeavored to perfect them, and by means of many measurements have obtained original data for disputed points. I have also studied individual variations to ascertain what weight should be given to them.

The first step in what I call the anatomical method is to place the spine correctly, which had best be done by putting the vertebræ, supposing them to be completely separate, in a bed of clay or of putty which will admit of their being moved until properly adjusted.

Three points call for consideration—the amount of cartilage to be represented in each region, the proportions of the different regions, and the curves; but in practice the first two are closely connected. Instead, therefore, of giving the statements of the amount of gristle to be represented in each region, I should proceed to give each region the proper proportionate length according to my measurements. I have made measurements following the curve of the spine from the atlas to the promontory on fifty male and on twenty-three female subjects with the following results, showing both the actual length of these regions and their percentages, the movable part of the spine being reckoned as 100.

	Male. Ctm.	Per cent.	Female. Ctm.	Per cent.
Cervical.....	13.3	21.5	12.1	21.2
Thoracic[1].....	28.7	46.3	26.5	46.1
Lumbar.....	19.9	32.2	18.7	32.7
Total.....	61.9	100.0	57.4	100.0

It is interesting to compare these results with those of others. Ravenel measured the spines of eleven men and eleven women and Aeby of eight men and eight women. Combining their results we have for nineteen of each sex the following proportions:

	Male.	Female.
Cervical.....	21.7	21.7
Thoracic.....	46.7	46.5
Lumbar.....	31.4	32.4
Total.....	99.8	100.6

In my measurements, as well as in these, the disks at the junction of two regions are reckoned with the upper one. It appears from this, and especially from my figures, that these proportions are essentially the same in the two sexes, though I agree with other authorities in finding the lumbar region a little longer in woman, relatively. It is clear that if the vertebræ are arranged so as to make the regions correspond to these proportions, the more intricate question of the amount of gristle belonging to each will take care of itself. The question of the curves is more difficult, and one which does not admit of a definite solution, for the reason that they vary in young people, at all events, with the time of day, and in all, except, perhaps, the very old, with the position of the body. Individual variations are also endless. It might be of use to follow Humphry's suggestion that a line dropped from the middle of the odontoid passes through the middle of the body of the second and twelfth thoracic vertebræ and through the anterior inferior edge of the fifth lumbar. Should a few vertebræ be wanting this system of proportions is all the more valuable. In case of an extra vertebra, which most frequently occurs in the lumbar region, I have found that the whole length of the spine is not necessarily increased beyond the average, nor always longer in proportion to the height, but that the proportion of the lumbar region is invariably so. In cases of only eleven thoracic vertebræ it is presumable that the thoracic region is short, but though I have several such specimens in my collection, unfortunately I have no measurements taken when the parts were fresh. I have records of a female spine with thirteen thoracic vertebræ in which the percentages were: cervical, 19.9; thoracic, 50.6; lumbar, 29.4; the length being 61.6 ctm., very long for a woman.

If it be asked whether anomalies of number in the spine are sufficiently numerous to be taken into account, I would say that in so far as this affects the proportion of the spine to the height it shall be considered later, that as far as it concerns putting the bones together it obliges the expert to disregard the arbitrary rules of proportions and to arrange the vertebræ as best he can. If there are no complications he should find this no insuperable difficulty.

It is to be observed that I disregard entirely the lower portion of the spine, as it is very liable to vary and has, moreover, no influence on the height.

The spine being settled, the next step is to put it on the pelvis. Of course the inclination of the latter has a great influence on the height, and unfortunately this is just the point which is most difficult to settle. As I stated in 1878, what Hermann von Meyer calls the nor-

[1] Read before the Association of American Anatomists at Washington, May 31, 1894.

[1] In accordance with a vote of the Association of American Anatomists, I have adopted the term "thoracic" in place of "dorsal."

mal conjugata is probably a more trustworthy guide than the conventional angle. This is a line passing from the top of the symphysis to the middle of the third sacral vertebra, on which a transverse line can usually be seen. This imaginary line forms an angle of thirty degrees with the horizon. We may, moreover, strive to make the notch of the acetabulum look directly downward and to bring the anterior superior spines of the ilia into the same vertical plane as the spines of the pubes. Nevertheless, many pelves will occur, especially those of which the first vertebra is transitional, for which the anatomist must rely on his general knowledge and good judgment rather than on rule.

The pelvis being then in place, the bones of the leg are to be added and due allowance made for the soft parts. In putting the thigh-bone into the socket care must be taken that it does not touch the upper border, from which it is separated by cartilage. The lateral inclination must also be borne in mind—in other words, the condyles must rest on a level. The very slight antero-posterior slant may be disregarded.

At the knee about 6 mm. may be added and about as much more for the two joints of the ankle. The addition of 12 mm. for the soft parts of the sole of the foot is not far off, though of course it is liable to variation. The skull is then to be placed, allowing 3 mm. for the joint between it and the spine, and about six for the scalp. According to Topinard 35 mm. are to be added to the skeleton for all these soft parts, a statement not materially different from mine. It is probably equally correct.

I shall now consider the application of the mathematical method, and later, cases in which the two may be profitably combined. The mathematical method rests on the proportion of certain bones to the height, and it is obvious that even if these proportions were collected from thousands of specimens, as Manouvrier remarks, these would give us no certainty. There are persons with short legs and persons with long legs, and therefore no single rule of proportion can be true for both. This method, therefore, is to be used when we can do no better. I shall show later what the possible error amounts to.

In medico-legal works some very insufficient tables are still quoted; but of late years this matter has received particular attention, especially in France, which has at last set this department of science on a comparatively stable basis. Three observers especially concern us. They are Topinard, Rollet, and Manouvrier.

Topinard calculates proportions based on observations giving the following ratios of certain bones to the height = 100: humerus, 20; radius, 14.3; femur, 27.3; tibia, 22.1. Thus, knowing the length of one of these bones, we have only to multiply it by 100, and divide it by the corresponding ratio. This should give the height of the skeleton, to which he adds 3.5 ctm. for the soft parts.

Rollet went further. He measured fifty male and fifty female bodies before dissection and measured the three long bones of each arm and leg. He then constructed tables, reckoned proportions, and gave five different methods of finding the height. Any one of the six chief long bones may be used, or the average result of calculation from each. His favorite method is by means of tables, one for each sex, and a simple rule of three. He proceeds thus: the length (L) of a bone being known, we find the length of the bone nearest to it in the table (B) and the average height (H) corresponding to B. Then we know that as $B : L = H : X$ or $X = \frac{LXH}{B}$.

He gives also a rapid method, which consists simply in multiplying the length of the bones by certain numbers. Thus multiplying the male humerus by 5.06, the female by 5.22, the radius by 6 86 or 7.16, the femur by 3.66 or 3.71, the tibia by 4.53 or 4.61, gives the person's height in centimetres.

The most recent paper is that of Manouvrier. He criticised Rollet's tables because of his hundred subjects fifty-one were sixty years or more. Their spines, therefore, had probably become shorter than normal, thus injuring their proportions. He formed, therefore, new tables from Rollet's by rejecting these fifty-one senile cases, which happily were divided as evenly as possible between the sexes, and by rearranging the tables so as to make the scale of the length of each bone the basis of calculation instead of the scale of the heights; obviously the proper course. He, moreover, measured the femur in its normal position instead of taking its greatest length, as Rollet, following Topinard, had done. Further, as these bones had been measured when fresh, he pointed out that in the case of dry bones 2 mm. should be added to their length. Finally, he claims that as the recumbent body, and the dead body presumably still more, gains in length, at least 2 ctm. should be deducted from the result in calculating the height of the living person. His method was then to look for the length of the known bone in his tables which gave the corresponding height. If the precise length was not there, to find its distance from the nearest and to make a suitable allowance in the height. Such is the mathematical method as applied to the long bones.

In a previous paper I attempted to find the ratio of the length of the sternum, excluding the ensiform cartilage, to the height of the body. My measurements embraced seventy men and thirty-nine women. I found that the average ratio in men was 9.65 per cent. By subdividing this set into groups I found that in the shortest men the sternum was relatively a little longer and in the tallest a little shorter, but the extreme variations of groups (not of individuals) was only from 9.56 per cent. to 9 98 per cent. The average of the thirty-nine women was 9.22 per cent. After the exclusion of a small number of cases the range of variation was remarkably small. Since then I have observations on seventy-nine men and thirty-one women which bring the totals to one hundred and forty-nine men and seventy women. The total average is 9.59 per cent. for the men and 9.08 per cent. for the women, showing that on the average the male sternum is distinctly longer relatively to the height. None the less this cannot be commended as a method of estimating the height in individual cases. The obvious reason is the very common occurrence of very peculiar sterna. It is one of the least stable parts of the skeleton. While I believe that a typical sternum has a fairly constant ratio to the height in each sex, variations are so numerous that this method must be discarded.

I have added a new method of my own, namely, the estimation of the height from the length of the spine measured in a straight line from the top of the atlas to the promontory of the sacrum, thus excluding the most variable regions, the sacral and coccygeal. The tables which I have used were constructed from measurements of fifty-six male and twenty-one female spines made after the completion of dissection, the basis being, according to Manouvrier's plan, the length of the spines, not the scale of heights. Instead of dividing the number of observations into equal parts, I have thought it better to arrange them in groups containing all the observations of every 3 ctm. Thus my fifty six male spines comprised three of less than 57 ctm. (the shortest being 56.4), fourteen from 57 to 60, twenty-four from 60 to 63, twelve from 63 to 66, and three longer ones (the longest being 69.8). I then reckoned the average ratio of each group to the height and found the coefficient by which to multiply any spine falling within any group. It is evident that this method, while giving very good data for the lengths represented by large groups, must be of little value for the extremes, represented by few bones. Still it seems to me more trustworthy on the whole than the plan of dividing the fifty-six spines into four groups of fourteen or into eight groups of seven. It makes all but the extreme groups more homogeneous. The weakness of these may be frankly admitted. As to the age of the subjects, several old ones have been admitted, thus twenty among the males were sixty or more and seven

among the women. Here I give simply the coefficients by which to multiply the length of spine. All that is needed is to find the group in which it belongs and multiply by the given coefficient.

Males.		Female.	
Length of Spine	Coefficient.	Length of Spine	Coefficient.
Under 57 ctm	2.93	Under 54 ctm	2.94
From 57 to 60	2.84	From 54 to 57	2.82
From 60 to 63	2.78	From 57 to 60	2.79
From 63 to 66	2.79	Above 60	2.76
Above 66	2.65		

As the spines grow longer the coefficient decreases, excepting that in the male table it is practically the same for two groups.

For several years it has been my custom to measure the height and certain other dimensions of subjects before dissection, and later to measure the length of humerus, radius, femur, and tibia, and that of the spine both in a straight line and following the curves. Anyone who has had experience in the dissecting-room will understand that for various reasons I often did not get all these measurements on both sides, nor of all these bones. Instead of constructing new tables of my own for the long bones I have chosen twenty male and twenty female subjects, with few exceptions under sixty years old. In all every humerus, radius, femur, and tibia had been measured on both sides and the average length taken as a starting-point. From this the height has been calculated from every one of the four bones and the average of the four results taken as the answer, according to the methods of Topinard, Rollet, and Manouvrier successively.

I have added in using Topinard's method the 3 5 ctm. which it requires. Perhaps I have been somewhat unjust to Rollet by using his rapid method instead of the one which is his first choice, but as presumably Manouvrier's modifications of Rollet's tables must be considered an improvement, the method I have followed permits us to judge whether this more complicated process, for which tables are necessary, has any marked advantage over Rollet's very simple rapid one.

I do not find any striking difference between the value of humerus, radius, femur, and tibia as a basis of calculation. Naturally, as I believe Manouvrier remarks, we should choose the longer bones as having the smaller coefficients by which therefore any error is multiplied a smaller number of times than if the bones were shorter and the coefficient larger.

In seventeen of each sex I have also the length of the spine. The tables are arranged according to heights. After each column is one of errors, showing whether the result was too great or too little. It is evident that the errors on the minus side very much predominate, the exceptions being by Topinard's method and by the spine in the male table. It is also seen at a glance that the worst results by all methods, and especially by that of the spine, are in the male table. The summing up at the foot of the tables is particularly instructive and curious. It shows that for the males, if we take the average error as the criterion, the methods rank in order of merit as follows: Topinard, Rollet, Manouvrier, spine; for the women the order is spine first, Manouvrier second, Topinard and Rollet practically even for third place. If we judge by the number of results within 2.5 ctm. the standing is materially the same. Comparing the results of the two tables, Topinard's method seems the best. In seventeen of forty cases his error is less than 2.5 ctm., and in thirty-two not over 5 ctm. There is little to choose between Rollet and Manouvrier, but as the latter's results for the most part err by defect I should not deduct 2 ctm. to make up for lengthening in the recumbent position.

On the whole it seems that in about one quarter of the cases the error is likely to exceed 5 ctm. or two inches. Conversely that in three-quarters of the cases it is possible to reckon the height reasonably closely. When we consider that the height is a variable quantity at different times of day and according to position, that moreover the accurate height of comparatively few people is known, we must feel that to come within one inch (as occurs in about one-half the cases) is very satisfactory, and within two inches is not bad. The fact must be frankly admitted, however, that a greater error than two inches is bad, and that this occurs about once in four times.

In studying the tables we find that the error from the spine is by no means always on the opposite side from the error from the long bones, as one would expect. In one case (653) the error by every method is very considerable, and all are by defect. I can only suggest by way of explanation (the possibility of some blunder being always admitted) that there may have been uncommon thickness of the soft parts, a large head, and great inclination of the pelvis. After writing these words I find in point of fact that the top of the trochanter is on the average of the two sides about 9 ctm. above the symphysis. This seems incredible; but an error in transcribing

these figures before dissection could have no connection with the subsequent measurements. I am inclined to believe, therefore, that the subject must have been a peculiar one. In some cases in these tables all the results are wonderfully concurrent, thus on a man (100, aged 31) the errors of the four results range from 2.4 ctm. to 1.5 and in a woman (746, aged 23) from 1.4 ctm. to 0.2.

As to whether the occurrence of anomalies of number of the vertebræ is so frequent as to throw discredit on the spine as a basis of calculation, the reply is somewhat uncertain. Since I have looked for such anomalies I have found them with a frequency which is surprising, though I am not able to express it in figures. I question, however, whether they give rise to any greater variation than comes from the uncertain length of the legs.

We have now to consider cases in which certain parts are wanting by supplying which we should be able not to rely solely on proportions. Let us suppose that the pelvis is wanting, or so shattered as to be useless, though we have both the legs and the spine. The problem is evidently how high to place the promontory above the trochanters. The height of the promontory above the symphysis is often stated as from about 3½ to 4 inches (say from 9 to 10 ctm.). This, I believe, came originally from Naegele's statement that in well-formed women it is about 3¾ inches. From my own observations I should give the distance at about 9.5 ctm for man and 10.5 ctm. for woman. We need, therefore, to know the relation of the height of the symphysis to that of the great trochanter. I find from measurements before dissection from 118 male and 37 female white bodies that in the males the trochanter is on the average 1.1 ctm. higher than the symphysis, and 3 mm. in females. Having in view the greater height of the promontory above the symphysis in women, we may without serious error reckon that the promontory is 10.5 ctm. above the trochanter in either sex.

Topinard [1] gives provisionally the following distances on a vertical line of landmarks above the hip in the male of medium height: From the anterior superior spine of the ilium to the head of the femur, 6 ctm.; from the head to the greater trochanter, 2 ctm.; thence to the pubes, 2 cm.

In certain cases we may have recourse to the proportionate height of the symphysis, which is admittedly not far from the middle in both sexes, although there are differences of opinion on certain points, as in particularly tall or short persons. From dissecting-room measurements of 110 males and 32 females I find that the pubic height equals in men 51.4 per cent., and in women 50.3 per cent.; the differences obtained by dividing like measurements of each sex into a longer and shorter half were absolutely insignificant, none reaching a half of one per cent. None the less I should esteem this proportion of most value in medium heights. Quetelet, it may be mentioned, puts the pubic height at .508 of the whole in man, and .498 in woman. Practically, considering the vagueness of the height and the insignificance of one-thousandth of it, we may for persons of medium height call the symphysis the middle point in women and a little (say 1 ctm.) above it in men.

Should the head be wanting we must make a suitable addition to the height of the spine. Sappey gives 13 3 ctm. as the average male height from the front of the foramen magnum to the vertex of the skull, and 12.5 ctm. for the female. To this 1 ctm. more should be added for the space between the top of the spine and the border of the foramen magnum and for the scalp, reckoned together.

Perhaps it might be useful to remember that the top of the spine is on a level with the anterior nasal spine and with the lower border of the auditory meatus.

Should the foot be wanting we might add for astragalus, os calcis, and soft parts 9 ctm. for man, and 8 ctm. for woman. I cannot, however, claim any great accuracy for this procedure.

[1] L'Anthropologie, fourth edition, 1884, p. 341.

By these methods it is, I believe, possible to estimate the height to within 5 ctm. in three-quarters of the cases when it is done solely by the method of proportions. When the most important parts of the skeleton are present there seems no reason why the error should ever reach that amount. Indeed the only reason why so large a margin should be allowed is the difficulty of knowing what the true height may have been, and the further fact that as it is not a constant quantity, it never can be known certainly.

CRIMINAL PSYCHOLOGY.

By JAS. WEIR, Jr., M.D.,

OWENSBOROUGH, KY.

In an article which appeared in the MEDICAL RECORD, January 13th, entitled "Criminal Anthropology," I showed by photographs and original sketches that the criminal was, anatomically and physiologically, an abnormal man, and also that he was, unquestionably, an atavism. With the permission of the reader I will quote some of the closing sentences of the above-mentioned article, and they shall form the text from which the present paper will be elaborated. "Atavism has hurled him" (the congenital criminal) "back thousands of years, and has placed him beside his pithecoid ancestor. He is a savage in the midst of civilization. His customs and desires, his responsibilities and religion are those of a savage, born and dead centuries and decades of centuries ago. . . . Poor unfortunates! Are they to be held responsible for Nature's vagaries? Enlightened humanity has a difficult problem to solve when asked the question, 'What will you do with the criminal?'" Ethics, concrete and abstract, are the result of psychical evolution. Abstract ethics, pure and refined, have reached a high point in civilized man, while concrete ethics, ethics necessary for the preservation of species living in communities (social law), have reached an equally high point among savages, and some of the lower animals, *e.g.*, the social hymenoptera and some of the birds and mammals. Most savages are purely animal in their natures, and have none of the refined psychical emotions which ennoble the possessor of abstract ethics, civilized man. Parental love, conjugal affection, fraternal love such as civilized man experiences, are unknown to the savage. Even the love of God is, with him, material and concrete. The love of the beautiful in Nature is, in the savage entirely absent, or, if present at all, it is only so in its material sense. His love of the beautiful (ornament) is rude and uncultivated, and, in its gratification he scarcely excels the rude decorative attempts of some of the lower animals, *e.g.*, the bower-bird, humming-bird, spider, etc. His æstheticism is coarse and unrefined, and, in truth, is not elevated above his gross animal desires. His drama, his poetry, and his art appeal to his carnal nature. He is essentially an animal devoid of every refined psychical emotion. I hold that the congenital criminal not only resembles the savage anatomically and physiologically, but that, psychically, the savage is also his archetype. It will be necessary, in order to prove this, to discuss the ethics and æsthetics of savages and compare them with the ethics and æsthetics of congenital criminals. Personally I am not acquainted with the psychology of the savage except for that knowledge derived from reading the observations of others, but with the psychology of the criminal I am thoroughly conversant, having lived with him in two of the largest cities in the United States.

In the following description of the savage and his habits, I have borrowed freely from the works of Hall, De Quatrefages, Nares, Lubbock, Markham, Lyons, Ross, Reclus, Day, and Bancroft. I will not, however, distract the reader's attention by sprinkling my text with references. The Eskimos or Inoits are a primitive race inhabiting the most northerly habitable portions of the globe; and it was in these people, before contact with civ-

ilized man had contaminated them, that we found evidences of concrete ethics and æsthetics, such as we have every reason to believe existed in all primitive races of men at, or, a short time after, the inception of psychical evolution. The Inoit habitation is communal; a whole community may dwell in one house. The central part of this house, where the ever-burning lamp is placed, is common to all. Cords are stretched across the other portions of the house dividing it into imaginary stalls or boxes, and these stalls are occupied by one or more families. There is no other fire save that of the lamp, which serves to melt the ice and snow for drinking-water. There is an utter absence of that which we term modesty. The inhabitants of the "kachim," owing to the great heat generated by so many bodies in one small room, strip off their clothes and go about entirely naked. "There is no natural want or physiological function which they hesitate about satisfying in public." They are dirty, squalid, ill smelling. They are unwashed, though fond of the vapor-bath; this they indulge in for the same reason that hogs will indulge in mud baths, for the gratification it affords. They sometimes bathe their faces in decomposed urine, but this they do for a religious, or, rather medico-religious fetisch, for they regard the bladder as the seat of the soul. The use of urine as an emollescent and a medicine is almost universal among savage races. The Wahabis and Ugoyos of East Africa, the Banians of the Momba, the Chewsures of the Caucasus, the Silesians, the Bedouins, and the Arabs all use it. Even in France and Spain it is used by certain people as an emollescent and a dentifrice. We will see, at the proper time, what a prominent place it occupies in the materia medica of the congenital criminal.

"In Aleutia those most nearly related to each other contract a union, the brother with the sister, and sometimes the father with the daughter." Langsdorf reproached an Aleutian for so doing; he replied, "Why not? the otters do it!" Between husband and wife there is no conjugal affection. They are not at all jealous. The Aleutian offers his wife to the guest as freely as he offers the chunk of seal-blubber. His friends are welcome to enjoy her if they are married and are in a position to return the favor. Immoral! Wrong! Not a bit of it. Remember that these people are mere animals and have no knowledge of abstract ethics; they see nothing wrong in a woman declaring that one husband is not enough for her. It used to be the custom in Florence for the women to demand in their marriage contracts the right to take a lover. The Aleutian girls, enjoying full liberty during their girlhood, demand at their espousals the right of the *cicisbeat*. During the absence of the legitimate husband the *cicisbeo* takes his place. Brothers frequently marry the same woman; in fact, among the Thlinkets and Koloshes, adelphogamy is the rule. The Nair girl calls in any man who is convenient and complaisant, who goes through the marriage ceremony with her, and places the *tali*, the Hindu equivalent of our wedding-ring, round her neck. He is feasted, and then politely shown the door. The wife is then at liberty to receive as many other men as she sees fit, but the husband—never! That would be disgraceful and highly immoral.

I might enumerate hundreds of kindred customs and habits in savage races, but do not consider it necessary; I merely wish to establish the fact that conjugal affection does not exist among savages. The savage mother has the same affection for her offspring as the cat or the dog has for hers. She attends to it just as long as it is helpless, "but as soon as it is able to look into the pot standing erect, she leaves it to itself and seems to forget all about it." Where polyandry exists it is not reasonable to expect that the man has any regard whatever for the children of his wife. This is true also where polyandry and polygamy exist combined together. In his poetry and his drama, and the savage is a born poet and actor, the savage depicts the scenes of his every day life. The events of the hunt, in the field or on the flood, are recited or acted with wonderful realism. Love enters into a number of their poems, but it is an intensely sensual love, a carnal and an animal love. Rapine, lust, and feasting go hand in hand, and tread the measures of every savage dance together.

The savage is a creature of to-day; he lets to morrow take care of itself. When there is plenty, he gorges himself with food to repletion; when there is nothing to eat, he fasts with stoical equanimity. Says Captain Lyons: "Knillitleuk had already eaten until he was half seas over. He was dropping asleep, with a red and burning face and open mouth. His wife was cramming him, stuffing bits of half-boiled meat down his throat with the help of her first finger, steering clear of his lips. She carefully watched the process of deglutition, and immediately filled up any void that might appear in the orifice with a stopper of raw fat. The happy man did not stir; he moved nothing but his molars, chewing slowly, and not even opening his eyes. From time to time a stifled sound escaped him, a grunt of satisfaction." The Mescalero Apaches tighten their belts around their empty stomachs and go in quest of prey, nothing, in the shape of an animal, comes amiss to them as food while out on a marauding expedition. Grasshoppers, lizards, snakes, a chance bird, anything is eagerly devoured in order to sustain life until they can make a grand *coup* on some unguarded ranch. At the right moment they rush in, kill the men, and carry off the women, children, horses, and mules. They then turn and strike a bee line for home, driving their captives before them, nor do they halt until they have regained their encampment, where they are received with yells of welcome. Immediately a bacchanalian orgy of feasting begins. A horse is knocked on the head and devoured before his flesh has ceased to quiver; nor do they stop for cooking until the edge of their hunger has been considerably blunted.

The savage is essentially a believer in witchcraft, and most of them are devil-worshippers. They are intensely superstitious, and see in every event of nature wonderful auguries and prophetical signs.

Among the Inoits and kindred races individual property does not exist. All things are held in common. When these people visited a ship for the first time, they picked up anything which pleased their fancy. They did not consider it stealing. "A man cannot steal from himself," said an Aleut; "what is yours is mine, and what is mine is yours. The Great Mother has given to all alike."

So much for the savage; now let us consider his congener, the congenital criminal, who, to a certain extent, is modified by his surroundings. When Marco Polo wrote his celebrated work people considered him a romancer. When an Indian returns to his tribe after a visit to Washington and relates to his brethren the wonders he has seen in his travels, they move their hands before their mouths and shake their heads. Deaf mutes make the same signs when they wish to express incredulity.

I expect that some of my readers will consider me a second Marco Polo, and will treat me with the same scant ceremony that the unsophisticated Indians bestow upon their travelled brother; yet I assure them, in advance, that the following history of the criminal is true in every particular. Men are prone to disbelieve because they cannot see the wound in the side with their own eyes, and cannot place the tips of their fingers in the punctured palms. St. Thomas was only intensely human, and I do not, therefore, have the poor opinion of him which most people have. Man is a veritable *terra incognita* to most men, though they do not know it, and when an observer tells them that he has discovered something new about man, doubting Thomases spring up everywhere. I only ask such critics to live as I have lived, with and among criminals, and they will soon cease to be infidels. I cannot be elaborate in a non-technical article, neither can I go into certain details without giving offence, but, stripped of unnecessary verbiage and absolutely devoid of all false sentiment, the following history is but a plain nar-

rative of the ethics and æsthetics of the criminal, revealed to me by a personal and intimate acquaintance with him in his daily life. Those in authority, whose duty it is to watch and guard against the criminal, will tell you that criminals herd together, and during my intercourse with them I always found them living in circumscribed communities. Remember always that in this paper I am speaking of the congenital criminal and not the professional criminal, nor the occasional criminal. Let me say, also, that the so-called "tough" is not usually a congenital criminal. The tough will fight and will commit other anti-social acts; he will even commit murder, but he is generally incited thereto by whiskey or by passion. He never commits murder for the sake of personal benefit like the congenital criminal. He is not an habitual thief, nor is he ever guilty of incestuous acts; moreover, the tough will work, but the congenital criminal never, unless compelled. The tramp is hardly ever a congenital criminal; he is, usually, only an occasional criminal.

Perhaps the reader will be interested in learning how I obtained my passport to thiefdom. I obtained it on one occasion in the following manner: In the first place, I called on the chief of police and explained the object of my researches and my plan of operations. I deemed this necessary, so that if "run in," I might have a friend at court. I then hired a room in an office building and furnished it with a desk and some chairs, and for several days, lounged about the low saloons in the poorest and most criminal section of the city. I saw any number of criminals, but bided my time; I was looking for a typical criminal, a chief in his tribe. I seldom or never make a mistake in my diagnosis of criminality, and so soon found the very man for whom I was looking. A few drinks of "red eye" and several "rum bolers," made him companionable. I explained to him that I had come to the city from an inland town where I had barely escaped being "pinched" for "flim-flamming;" that I knew where a "trick could be turned" in the city if I had some one to help me. He readily agreed to furnish the tools and render me all the help necessary for half the "boodle," so I deliberately planned with him to rob my own room. I had placed in the desk in this room twenty five dollars, and to make a long story short, I assisted him in burglarizing my own room and in robbing myself. We divided the money, and he, as I expected, then invited me to go with him to his "mot cab," *i. e.*, woman's room. It was here that I made the acquaintance of the congenital criminal. This colony of criminals numbered about two hundred, and were herded together—men, women, and children—in two small tenements. Sometimes a dozen men, women, and children would be found occupying one small room. No modesty was observed by these people. A tub or bucket did duty as a necessary, and the calls of nature were attended to publicly. As it was summer, and the weather very warm, these people stripped themselves naked when in their rooms, the younger ones even running about the house and into the courts entirely nude. The women had their favorite "cully," but almost everyone of them practised polyandry. Some of them did this secretly, but most of them were open in their adultery, and the men were fully aware of the fact. Prostitution was a source of revenue in which the putative husband shared without any shame or compunctions of conscience. He only grumbled when his "mot" did not bring in much money. In this colony I saw two examples of incest, one a father living with his daughter, and another, a brother living with his sister. There were probably many more instances, but they were cursory and did not attract my attention. These people were fully aware of the fact that these acts were considered criminal by people not belonging to their tribe, and that they would be punished if apprehended. They had nothing to fear, however, from their associates, for, like the Aleutians, they saw nothing wrong in it. "Why not? the otters do it!" When the head of the family goes off on a marauding expedition, and he is frequently absent for weeks at a time, he leaves his partner in charge of the family. This man is the *cicisbeo* of the woman, and during the absence of the husband fulfils all of his duties. These men are true savages in the treatment of their women; they beat and maltreat them on all occasions, and almost every woman in the colony bore the marks of her "cully's" brutality. Here, also, I saw many instances of sexual perversion. These disgusting performances cannot be described or even hinted at. Suffice it to say that the religio sexual abominations of the Aleutians have their autotypes among their civilized (so called) congeners. The girls become prostitutes early in life. They are nominally match sellers or flower-venders, and do a thriving trade among the brokers and various agents, etc., who have their offices down in the city. One little girl, not ten years old, showed me a twenty-dollar gold-piece which she declared had been given her by a certain "grave and reverend seignior," high up in banking circles. The money which these precocious little sinners (ought I to call them sinners? I am convinced that they do not consider themselves such), take in is given to their mothers. When these girls arrive at a marriageable age, say from fourteen to eighteen years, they "take up" with some man in the colony and become his "mot," or woman. The boys are thieves from earliest childhood. They sometimes sell newspapers, but do this merely to mask their real business, which is pocket-picking. When older they become sneak-thieves, thugs, and burglars. The criminal, like the savage, is improvident and wasteful. When he has made a successful haul he lives on the fat of the land. The "growler" fairly smokes, it is "rushed" so rapidly. The pots and kettles in the scantily furnished kitchen corner are filled to overflowing. The women are all engaged in rude cookery, while the men prepare for the coming feast by stimulating their stomachs with numerous potations. The dinner is served and all fall to, like veritable savages as they are, and eat and drink until slumber overtakes them. The criminal delights in bright colors and tawdry jewelry. His æstheticism, like that of the savage, is rude and uncultivated. He will cover his fingers with enormous rings, and will wear cravats and handkerchiefs of the most pronounced colors; he does this, however, when on dress parade. When on business bent, like the savage, he, almost literally strips himself to his breech-clout; he does not care to have his movements hampered by "bum togs" when he is about to "crack a box." He is filthy and uncleanly in his habits; he never bathes from one year's end to another. Parasites swarm on his person, and the odor of his body is rank and animal-like. His knowledge of medicine and the kindred sciences is crude and savage. Incantations, sorceries, and simples (some of the latter are horrible and disgusting compounds) are his materia medica. I accidentally sprained an ankle while with these people, and was treated by an old crone of the colony. She bathed the foot and ankle with decomposed urine, all the while mumbling:

> "From toe to knee, from knee to toe,
> In and about the devils go;
> Chase 'em, liquor, chase 'em fast,
> And from this foot drive 'em at last."

This treatment proved very efficacious, for the pain vanished and the swelling disappeared as if by magic. Urine is a favorite lotion with the congenital criminal. The women use it as a face wash, and the men consider it the best medicine in the world for bruises and contusions.

The congenital criminal has his god, but he is not the God of the Christian. He is the god of luck or chance, and his wishes are consulted and obeyed with as much fidelity by them as are those of the Christian's God by his devotees. Bad Luck is their devil, and he is treated with as much consideration as his antithesis, Good Luck. Here is where the devil-worship of the Aleutian is paralleled. Here we see an evidence of concrete ethics such as we find in all savages; there is no abstract love of God such as civilized Christians feel. The congenital criminal, like the savage, recognizes the good and evil

principles, but he applies them to his personal welfare and not to his spiritual. He is a savage, and the idea of morals has not yet been evolved in his brain.

The savage and the congenital criminal are born poets, and both love a certain kind of play-acting. Like the savage, the criminal likes to witness scenes akin to his every-day life and aspirations, acted on the stage. The border drama, in which there are many murders and much crime, is his great delight. He cares nothing for comedy, unless it is obscene and lasciviously suggestive. He loves music and dancing, but both the music and the dance must be carnally exciting, or he will have none of them. He is a poet, and almost invariably speaks in figurative language; so is, and does, the savage. His poems depict his every-day life, because he is, from the nature of things, essentially a realist. All are familiar with the lucubrations emanating from our jail birds. Most of the poems obtained by myself cannot be printed. Some of them are real poetry, though based on obscene and lascivious topics, and expressed in rude, slangy language. The criminal is an artist also, and his work is strikingly like that of the savage. His drawings are mostly pornographic, depicting men and women in immodest and lascivious attitudes, and according to Mayhew, savages are guilty of the same thing. The congenital criminal is born with his tendency to criminality firmly stamped on his brain; it is an inheritance from his father and his mother. He considers the laws of society to be all wrong; his social laws, *his* ethics, are the only right ones. His logic is all wrong with us, but all right with him. The congenital criminal is a moral imbecile; no amount of punishment will ever evolve in his brain any idea of morality. This is an established fact, and cannot be gainsaid. But he is anti-social, therefore dangerous: what shall we do with him?

PROVISIONAL TREATMENT OF INSANITY.

By SANGER BROWN, M.D.,

CHICAGO, ILL.

LATE ACTING MEDICAL SUPERINTENDENT OF THE BLOOMINGDALE ASYLUM, NEW YORK; PROFESSOR OF MEDICAL JURISPRUDENCE AND HYGIENE RUSH MEDICAL COLLEGE; ATTENDING NEUROLOGIST COOK COUNTY HOSPITAL; MEMBER OF THE LONDON NEUROLOGICAL SOCIETY.

I WISH to deny at the outset any intention of assuming a hostile attitude toward the asylum treatment of the insane, or that it is the main purpose of my communication to advocate the home treatment or care of the insane. I preface what I have to say in the above manner in order to escape, if possible, from the imputation, which a hurried reader might charge to me, of being in the main opposed to the asylum treatment of insanity, and in a general way favoring by preference the home treatment of the disease. I do this because experience has taught me that in medical societies or gatherings, where I have thrown out any suggestions along the lines considered in this paper, I have almost invariably been misunderstood by a few at least, if not by the majority. I feel, however, that the subject is one of considerable importance, and even at the risk of being misunderstood I shall venture to express myself upon it.

My principal proposition is that when it is demonstrated in a given case that insanity actually exists, it does not necessarily follow that it is the best practice to immediately send the patient to an asylum. It is the purpose of this paper to present arguments in support of this proposition.

From fifty to seventy five years ago the asylum or madhouse was for the most part a place for the custodial care of violent or dangerous lunatics, and it was rather the exception that the chief officer was a medical man; and if a medical man, it was perhaps a still greater exception if he devoted much time to the actual study of insanity in its varied aspects. Howbeit there were a few conspicuous exceptions, and by way of digression I want to take this occasion to say that we are more indebted to them for the advancement that has been made in the treatment of the insane than we are generally aware of. It was the common practice in those days to leave the care and treatment of the insane in asylums mainly to the attendants, the physician seeing and prescribing for them mainly at the attendant's suggestion; in many instances large quantities of the favorite "sleeping potions" and "quieting draughts" were placed in the hands of attendants with instructions how to use them. As can readily be understood, it generally happened in these times that the attendant really knew much more about the actual problems of treating the insane than the physician, and if he told the physician that this patient needed quieting medicine, and that one must be kept strapped to a chair, and another must be kept locked in his room, his word was law, and said patients were often so treated, not for days and weeks, but continuously for long months and years. But, somewhere about twenty or thirty years ago, resident medical officers more or less generally began to actually make a study of the care and treatment of the insane, until now it is rather the exception for attendants to know more about any part of the treatment of insanity than asylum physicians. Though it would be both instructive and interesting to trace step by step the changes as they have occurred, it may be asserted quite safely that within the above-mentioned time there is no department of medicine in which there has been a more striking metamorphosis or a more practical advancement.

Cases that for years had lived behind bars, in their own filth, having their food passed to them, either in the public jail, public mad houses, or at the house of some relative, under the new order of things in the modern asylum were often, much to the astonishment of their relatives, found in a condition of cleanliness and comparative comfort, successfully employed at some healthful out-door occupation.

To all classes of observers this change appeared quite marvellous, and to none more so than to the general practitioner of medicine, so that he, urged on by the reports of the medical officers of the hospitals for the insane, soon came to adopt the routine practice of promptly sending all patients to an asylum whenever the existence of actual insanity was demonstrated; and on the whole it is probable, if the practitioner had never served on the medical staff of an asylum and thus had an opportunity of gaining a practical acquaintance with insanity, that this was the wisest course for him to pursue. He did not know at all how his patient would be treated when he reached the asylum. He was only thoroughly convinced from his reading and observation that to send the patient to an asylum was the proper thing, and he often surmised that there were some mysterious influences in operation which were in some way beneficial and which were favored by the association together of a comparatively large number of the insane. This, like most surmises, was very far from the actual fact.

To prevent the patient from injuring himself or others, to see that he have proper food, rest, sleep, exercise, occupation, and diversion, and do not fall into pernicious habits, is the main purpose at the asylum; it is not easier to do this with two or more patients than with one, it is only more economical; it could always be somewhat more effectively accomplished with one patient. There is no mystery about it whatever; natural aptitude and a thorough familiarity with the various phases of the disease are the essential elements of success in the treatment of insanity, if only the necessary funds are at hand.

Now, while it is always within the power of the very wealthy to equip a private establishment, with a resident medical attendant for the exclusive treatment of a single individual, and whether the case is curable or not such treatment may be made superior to any other, it often happens that cases are seen where, without any great expense the indications of treatment can be better carried out, say in a general hospital or a private family other than that of the patient, than in an asylum, and if it be a young person with an acute attack, a considerable ex-

pense ought to be incurred in order to provide, for a time at least, proper treatment outside of an asylum.

Asylums have grown to be so numerous and such a large number of young medical men are employed as assistants, that now there is coming to be quite a large sprinkling of practitioners outside of asylums who have a practical knowledge of insanity, men who know when brought in contact with a case how it ought to be treated, and whether, in view of all the circumstances, it is necessary to hurry the patient off to an asylum or not.

I shall not at this time attempt to describe the particular class of patients most suitable to non asylum or provisional treatment, nor the measures to be adopted to meet these indications, my purpose being to try to impress upon the mind of the practitioner the importance of carefully studying every case of insanity, satisfying himself as to the diagnosis and prognosis and then considering how the indications for treatment may be best met.

Such cases are often somewhat perplexing and troublesome, and I fear it has been too much the practice of late years, sanctioned by usage, not by science, to dismiss them hastily to an asylum, without due regard to facts or consequences.

34 Washington Street.

Progress of Medical Science.

The Effect upon the Nursling of the Mother's Diet.—The feeding of infants on artificial foods is a growing evil for which, although they inveigh against it, physicians are in a large degree responsible. Efforts are made to explain the evil away on such grounds as the desire of the mother to avoid the inconveniences of her natural duties, or of changed conditions of life causing inability to furnish food in sufficient quantity, if at all, or of deficient quality of the mother's milk, or other conditions, for all of which the mother is responsible. These conditions do exist in a greater or less degree, but aside from actual and acute disease, the maternal conditions may be tersely summed up in the statement that the mother is unwilling to make the sacrifices necessary if she performs her duty to her child. The responsibility of physicians lies in weakly conceding to the patient's desires, in place of strenuously insisting upon the mother's every effort to carry out the provisions of nature.

In these days of milk-foods, prepared foods, substitutes for mother's milk, etc., mothers do not understand that the nature which provides organs for bearing children, also provides organs for nursing children, and intends that these organs should be for use rather than ornament. She does not realize that the products of modern science at best are but poor substitutes for the products of nature. If the physician would insist upon the mother performing her natural functions despite her assertions that she "cannot nurse the child," "never could nurse her children," "didn't have milk enough," "nipples too small or too tender," or "milk left her in two or three months," etc.—if the physician should insist, and the mother persist, both would be surprised to find that long abused nature would still be willing to do her proper work. Patient endurance of discomfort, persistent effort, and proper food will eventually demonstrate the ability to nurse their infants, in nine out of every ten mothers who assert the necessity, in their individual cases, for "bringing up the baby on the bottle." And that, too, without scouring materia medica for imaginary galactagogues, and likewise to the very great benefit of both mother and infant.

During his six years' service at the Preston Retreat Dr. Joseph Price gave the medical profession, through that institution, some most valuable object lessons in obstetrical science. There was no secret in the methods used to make that institution the model maternity of the world, so far as professional results are concerned. His guiding principles were care, cleanness, and common sense. The strictest supervision of every detail, scrupulous practical cleanness and not so much of theoretical cleanliness, and simplicity in all matters, enabled him to complete his service with a mortality record never equalled in private or public maternity work. It was a law with him "to allow the mother to bear her own children," and it was equally the rule to require each mother to nurse her own infant during her stay in the institution. So very rare were exceptions to this rule necessary, that a nursing bottle could not be found in the entire institution. The patients in the Retreat were in no respect an exceptional class, save in the fact that so large a proportion of them were ill-nourished and impoverished in physical health when they entered the hospital—conditions which would entitle them to claim inability to nurse infants. Another fact of interest was noted, namely, that many mothers, who while in the house furnished abundant food-supply, and left the institution with thriving babies, would, after leaving, put the baby on the bottle as a matter of personal convenience, and in a surprising proportion of such cases would lose the babies within a few months.

The moral to be drawn is that almost every woman who can bear a child can nourish it. Attention to the body functions, generous supply of simple, nourishing food, and early and persistent efforts to establish and develop the mammary secretions were the only methods used to secure these results. In general practice the physician is too apt to give up the contest too early or to rely upon some form of stimulants to the glands, which eventually proves delusive if not injurious. It is a common practice to administer alcoholic beverages in the form either of ale, beer, or porter to nursing women for the purpose of increasing the milk supply. Beyond question these articles are capable of doing much injury to both mother and child, and their indiscriminate employment for such purposes should be interdicted.

Dr. J. W. Byers, in the *Annals of Gynecology and Pediatry*, has made some pertinent remarks on this subject. He says: "The truth is, in this practice of using alcoholic drinks the profession has followed the customs and whims of the laity, rather than the usual process of instructing and leading the latter. That there are conditions and circumstances in which the administration of malt liquors is of decided benefit to both mother and child, no one will undertake to gainsay. But that they are indicated in every instance of deficient lacteal secretion, or that the exigencies of the case ever render necessary their use to the extent as is commonly employed, none can maintain or justify. The promiscuous and general practice of using malt liquors by nursing women is irrational, does a vast amount of harm, and often causes disease in the suckling. We know that the mammary gland, for all practical purposes, may be considered as an organ possessing functions of a twofold or mixed character, namely, secretion and excretion. Under normal physiological conditions the first of these processes is in almost exclusive operation, though, as shown by experiences, the slightest alteration in the condition of the organism, whether of an emotional, medical, or dietetic character, may so change this secretion that it becomes to all purposes and effects an excretion, and an innocuous, healthy pabulum for the child is converted into a deleterious or poisonous substance. Experience is very general in showing that the milk fats and albumins in increased proportions have a decidedly injurious effect upon the digestion of the infant when taken into the stomach in excessive quantities. From a number of experiments conducted by Zaleski he found these substances in the milk in excessive proportions whenever the mother had partaken of alcohol. In each case where the mother was tested with malt liquors, the fat and albumin appeared and caused more or less disorder and distress of the digestive apparatus of the suckling. These deleterious influences, however, were not the worst. Analysis of the milk further revealed the fact that it

actually contained alcohol and the micro-organisms peculiar to malt liquors; that the liquor drank by the mother actually passed out *in toto* through the mammary gland and on into the child's stomach, and there produced all the phenomena incident to digestive disorders and febrile disturbances. These facts point to the belief and support the attitude, that the mammary gland under certain conditions exercises the function of an excretory organ, and that under some circumstances it becomes nothing more than a filter through which the food and drink taken by the mother passes directly into the stomach of the child. This being true, we are in a position to understand and appreciate the importance of the relation of the diet of the mother and the well being of the child. When we prescribe alcohol for the mother, we at the same time do so for the child. The diet of the mother is a stage in the milk-producing process, and the milk she produces, is, in every instance, the result, and only the result, of the food of which she partakes. If it be improper, unsuitable, or contaminated, the milk will express this in a proper ratio. In the case that beer or ale is administered it will find this outlet, and while it does not evidence deleterious influences to the extent of producing the worst results in the form of either colic, indigestion, or diarrhœa, in every instance its effects are present, and these are always among the possible results of its use. The effects of fat and albumin, when present in breast milk in excessive proportions, in producing evil effects on the child are too well recognized to dwell upon. That the more severe of stomach disorders—gastro-intestinal catarrh, enteritis, or even cholera infantum—are due to these substances, as a result of the abuse of malt liquors in the mother, is certain, though such is not generally admitted or recognized. Take care not to advise a woman whose milk supply is reasonably full to resort to beer or other liquors in order to increase it. Always impress upon them the increased risk to the child incurred by using them."—*The Medical and Surgical Reporter.*

modest spirit is hardly in keeping with the revolutionary nature of his doctrine. He admits that the modern physiologist, with microscope in one hand and his last mounted slide in the other, is undeniably sceptic about all matters incapable of material demonstration, and sometimes overlooks the fact that much, if not all, progress is but the pursuit of theory.

We cannot follow the author too closely in his chase of theory, though the mental exercise is doubtless bracing and exhilarating enough. Dr. Cullen is lucid in style and simple in diction. There is no mistake about his views. For example:

Concerning the ovule, he personally inclines to the belief that, "apart from the theory of continuity provided by the latent germ idea, which, up to a certain point, seems

Dermographismus.—Dr. Ehrmann describes a peculiar condition of the skin occurring under various circumstances, and depending for its appearance upon mechanical irritation. He distinguishes three degrees of this condition: In the first there appears one after another contraction of the cutaneous muscular tissue, with anæmia of the parts affected, then hyperæmia, and finally transudation; in the second the muscular contraction is very slight, the anæmia is not so marked, and there is hyperæmia of the superficial layers of the skin only; and in the third there is only transitory reddening of the skin. But the more common form of case is that in which, on the portion of skin affected, small raised patches of œdema appear around the roots of the hair, so that on stroking the skin with some blunt body, or even by the pressure of the clothes, or a button, etc., only an isolated group of white papules appear, which cause an irritation of the skin and consequently soon lose their characteristic appearance, owing to being scratched by the patient. In such cases cutaneous pruritus is diagnosed a "pruritus nervosus." In some cases recorded the appearance closely resembles that of lichen ruber planus. Ehrmann draws a distinct difference between dermographismus and urticaria. The latter is caused by the action of some toxic substance, this being derived from some affection of the skin or of the digestive organs, or some pathological products are formed (auto-intoxication); but he admits that in some cases of urticaria, in which the nervous system is affected, that disease and dermographismus may exist together. This condition has been observed after mental excitement, such as fright, or in cases of neurasthenia and hysteria. He considers the influence of the nervous system as sufficient to produce dermographismus, and that the presence of a toxic substance is not necessary. Examination of the urine demonstrated the presence of indican in only one out of fourteen cases.—*Allgemeine Wiener Medicinische Zeitung.*

Epidemic Skin Disease.—At a recent meeting of the Dermatological Society of Great Britain, Dr. Savill showed eleven cases of dermatitis which had attacked nearly five hundred children in a day school where the average daily attendance was about one thousand. (*The Lancet.*) It was thought by their teachers to be ringworm of the face, and they were taken to a neighboring hospital for such, but it was shown not to be ringworm because the scalp had not been attacked by the disease in any case, and no characteristic spores or mycelium could be found after careful search. Moreover, the disease resembled a dry eczema occurring in patches, not healing in the centre as ringworm does, nor had they the raised border. They were chiefly on the face, though some of the children had patches on the arms and legs. In the discussion which followed, Dr. Stephen Mackenzie regarded the condition as a common and comparatively trivial affection; but Dr. Savill pointed out, in reply, that the cases of these children very closely resembled the youngest of the cases with the epidemic skin disease described in 1891. Many of the cases of this disease he had subsequently seen (such as those at the Bethnal Green Workhouse in 1893) had been very much milder than the 1891 cases; and it would be a matter for subsequent inquiry and research whether the cases of these school children belonged to the same category or not. At any rate, there seemed evidence to show that the disease, whatever it might be, was a contagious one, spreading as it had done so extensively in this school among children who, when not at school, must live under such varying conditions of environment that it would be hard to find a local cause in operation common to them all.

Treatment of Appendicitis.—Dr. Swain holds that, since about ninety per cent. of cases of appendicitis recover spontaneously, early operative interference in nearly every form of appendicitis is not justifiable. (*Therapeutic Gazette.*) Cases of simple and plastic appendicitis are to be treated by rest in bed, moderate amount of liquid diet, purgatives, rectal injection if necessary, local application of leeches or fomentations, and hypodermics of morphine for the relief of pain. As soon as pus is present operation is indicated. This may be performed during the first week, but is more commonly required during the second. When in doubt as to the presence of pus, there is usually no great harm in delaying operation. If, however, the symptoms are steadily growing worse and the pulse becoming rapid, operation is indicated. Section, then, is called for in suppurative cases, in cases where there is good ground for suspecting deep suppuration, and also in the relapsing and rapidly perforating cases. The best incision is the oblique one, placed at right angles to an imaginary line drawn from the right superior iliac spine to the umbilicus. This should be from two to four inches long, and should be placed about two or three inches internal to the iliac spine. In suppurative cases the incision should be placed over the seat of suppuration, since thus there is less risk of opening the peritoneal cavity. The appendix should be removed in suppurative cases only, when this operation is readily effected without opening the general cavity.

The risk of fecal fistula is lessened by suturing the muscular and mucous walls of the stump of the appendix, and then invaginating this into the cæcum and stitching the peritoneum over it.

Safranin Reaction in Sputum.—A simple test as an aid to diagnosis is suggested by Zenoni. (*The Lancet.*) It depends upon the fact that mucin is colored yellow by safranin, while albumin is stained red. In the sputum of bronchitis mucin predominates, while in that of pneumonia there is a much larger proportion of albumin. Zenoni, therefore, prepares a cover-glass specimen of the sputum by spreading the latter out in a thin layer on the former, places it at once in absolute alcohol, and leaves it for a quarter of an hour; by the end of that time the film becomes coagulated and fixed to the glass. The preparation is then stained in a half saturated aqueous solution of safranin. When the cover-glass is removed it is partially dried and then placed on a white ground and examined. If it is stained a yellow color mucus predominated in the sputum, and the case may be assumed to be one of bronchitis only, while if a red color appears albumin was the chief constituent, and pneumonia was probably the condition present. This test, if proved to be trustworthy, would be a considerable aid to diagnosis in those cases in which the physical signs of pneumonia are doubtful. Especially would it be of value in the case of children if a sample of sputum could be obtained, as can usually be done with a little trouble. But further trial will be required before it can be generally accepted.

The Surgical Treatment of Perforation from Gastric Ulcer.—Few cases offer more temptation to the adventurous surgeon, and in few, unfortunately, have his endeavors been rewarded with less success than those of rupture of a gastric ulcer into the peritoneal cavity. The affair seems, on the face of it, so absolutely simple; the patient may be in perfect health, with the exception of this little perforation and the resulting extravasation of the contents of the stomach into the peritoneum, and, moreover, in the majority of cases in which the rupture has been sudden and the symptoms typical, the perforation has been in accessible regions—on the anterior wall of the stomach—and yet, so far, few attempts to sew up the opening seem to have been attended with success. Great interest, therefore, attached to the case reported by Mr. Morse, of Norwich, England, in which a young woman having symptoms of gastric ulcer was suddenly seized with symptoms of perforation, and was treated by him successfully by means of celiotomy and suture of stomach. Abdominal section was performed within five hours of the accident; the contents of the stomach were found in the peritoneal cavity; the viscus was withdrawn and a perforation found; the stomach was thoroughly washed out and the wound united. No food was given by the mouth for sixty hours, and in three weeks the patient was well. The points of importance conducing to the success of this case would seem to be, 1, early operation, before irrevocable septic mischief has arisen through absorption from the peritoneal surface; 2, washing out the stomach as a preliminary to introducing the sutures; this was managed by introducing a large cannula through the perforation, and alternately filling this viscus with water and emptying it until the fluid came away clear; 3 drawing the stomach out through the wound, so as to perform the washing and suturing with facility; and 4, most important of all, the very great care taken to thoroughly wash out the peritoneum. The manœuvre adopted by Mr. Morse, with this object, will probably be useful for other purposes also. Instead of merely passing a tube to the various regions of the abdomen, leaving the return water to wash out the fragments, two large tubes were passed side by side to every part of the cavity, and the flushing was continued at each spot until the return fluid was clear; by this arrangement the extravasated stomach contents were washed out through the tube, instead of drifting in the stream from one part of the abdomen to another. It is to be hoped that other surgeons will be able to obtain like success in the treatment of this otherwise very fatal accident. On a very different footing stands the proposal to treat perforation of the bowel in enteric fever, as was shown by the discussion at the Medical Society of London on March 9th. The patient is already seriously ill, and, although the accident, of course, happens suddenly, the signs of its occurrence are often by no means typical. The stupor of the patient leads to the symptoms being more or less masked, the moment of onset may not be discoverable, the pain may not be severe, and the patient may only seem to pass from a bad into a worse condition. Moreover, the ulcers are generally multiple and the intestine rotten, so that the stitches may have to be inserted in unhealthy tissues, possibly even in the bases of other ulcers! A certain number of such cases also recover under medical treatment. The operation, then, would seem a much less hopeful one than that for perforation of gastric ulcer.—*Medical News.*

Extramedian Incision in Laparotomy.—Dr. Flatau has, since 1890, abandoned the practice of cutting in the median line in ovariotomy and other abdominal operations performed on women. Out of thirty-three cases where the incision was made outside the middle line, not one has been complicated by hernia of the cicatrix. He cuts one centimetre, or two-fifths of an inch, to the left of the linea alba, laying bare the rectus, the fibres of which are easily parted (*The British Medical Journal*). In only three or four of the cases did he divide an artery that required ligature; pressure forceps were always sufficient to stop hemorrhage from veins. After a little gentle pressure on the muscle all oozing ceased, and the wound was quite dry by the time the peritoneum was divided. Flatau objects to washing the edges of the wound with carbolic lotion, as the irritation thus set up may interfere with immediate union. He has never met with any difficulty in manipulating on the right side of the abdominal cavity, the incision being [illegible]

Dr. J. W. Byers, in the *Annals of Gynecology and Pediatry*, has made some pertinent remarks on this subject. He says: "The truth is, in this practice of using alcoholic drinks the profession has followed the customs and whims of the laity, rather than the usual process of instructing and leading the latter. That there are conditions and circumstances in which the administration of malt liquors is of decided benefit to both mother and child, no one will undertake to gainsay. But that they are indicated in every instance of deficient lacteal secretion, or that the exigencies of the case ever render necessary their use to the extent as is commonly employed, none can maintain or justify. The promiscuous and general practice of using malt liquors by nursing women is irrational, does a vast amount of harm, and often causes disease in the suckling. We know that the mammary gland, for all practical purposes, may be concase, where the first one half-grain dose produced sickness and vomiting; but even here subsequent doses produced no bad effects. On two occasions the pulse was felt to be somewhat irregular while the drug was being administered. The drug lowered the temperature, and the subsequent reactionary rise of temperature was unaccompanied by shivering except in one case out of about three hundred and sixty miscellaneous cases in which the drug was given. The great advantage claimed for lactophenin in typhoid fever, however, is its sedative action; delirium vanishes, the mind becomes clear, and the patients all experience a pleasant subjective feeling, such as is given by no previous method of treatment; appetite quickly appeared in all cases. To what extent chance played a part in the happy results obtained, and whether the drug really cuts short the course of the disease must be left as questions to be decided by further observations. No protection against hemorrhage or relapses can be expected from this drug any more than from other methods of treatment.—*Centralblatt fuer innere Medicin.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street

New York, September 8, 1894.

PATERNAL IMPRESSIONS.

A SEX war is threatened. While the retention of the time-honored "male" in the Constitution is trembling in the balance, a British innovator is making a stealthy claim for the recognition of "paternal" impressions over the well-known maternal variety of prenatal influence. Dr. Cullen is the "surgeon-accoucheur," as he styles himself, who unblushingly publishes in the *Provincial Medical Journal* his vindication of fatherhood in so serious a matter as the transmission of impressions to the unborn.

It is quite safe to assume that an outraged motherhood will not calmly submit to this unheard of masculine encroachment on a prerogative founded in nature and sanctioned by medical tradition.

At the outset of his learned discourse the "chirurgien-accoucheur" is inclined to be a trifle apologetic, which modest spirit is hardly in keeping with the revolutionary nature of his doctrine. He admits that the modern physiologist, with microscope in one hand and his last mounted slide in the other, is undeniably sceptic about all matters incapable of material demonstration, and sometimes overlooks the fact that much, if not all, progress is but the pursuit of theory.

We cannot follow the author too closely in his chase of theory, though the mental exercise is doubtless bracing and exhilarating enough. Dr. Cullen is lucid in style and simple in diction. There is no mistake about his views. For example:

Concerning the ovule, he personally inclines to the belief that, "apart from the theory of continuity provided by the latent germ idea, which, up to a certain point, seems incontrovertible, the latent germ contains very little of the individuation of the parent organism prior to the beginning of maturition in the Graafian follicle, and that the inheritance of the maternal characteristics continues from that point to impregnation and onward to the expulsion of the embryo from the uterus. The element of chance, which forms a law in the pollination of plants, has no analogy here, since the conditions are not similar, for we presume that ovules and spermatozoa are equal one to the other, and capable of similar results under similar and suitable circumstances."

It is certainly comforting to be assured that the human father does not procreate in the haphazard fashion of plants. This brings us to the author's chief contention, namely, that the male element has influences upon the female beyond that of mere fertilization, and that these influences should be termed paternal impressions.

The following narrative ought to be conclusive to all except frivolous sceptics: "A friend, resident in Springbarn, possessed a fine female dog of pure Dalmatian breed. Accidentally she mated with another who was no choice of her master, and, to the latter's supreme disgust, presented him with a generation of collie mongrels. This was bad, but when informed that his Dalmatian was now ruined for breeding purposes, he declined to credit the statement and resolved to test it for himself. In process of time he had her warded by a pure, male dog of her own breed, belonging to a gentleman in Kilsyth, and on this occasion she dropped six puppies—three of them, however, being perfect collies to such details even as the claws. Here, it is evident that the mother not only impresses the conception, but the conception retaliates with the paternal impress. The same law holds good with swine, cattle, horses, and other animals. Nisbet, in 'Heredity and Marriage,' refers to it as occurring among widows who have married again and borne children resembling those by their first husbands. Sir J. Y. Simpson related to Dr. Harvey a similar fact. Poultry may bear a sequence of fecundable eggs from one impregnation. This is an allied paternal impression."

The eminent "chirurgo-obstetrician" is at all events impartially complimentary. After having told us that husbands are more circumspect than plants, he makes "honors easy" by informing the reader that "widows who have married again" may be classed with certain mammals and selected poultry.

What have the ardent woman suffragists to say about the next quotation?

"In attempting to explain paternal impressions it is necessary to prove paternal superiority. That woman is not the aggressive equal of man is a fact and not a fault. Menstrual, maternal, mammary, and emotional features in her nature prevent her equality, and where a striking individual exception has occurred it has been at the expense of what we define as feminine characteristics. The intellectual female becomes masculine from the very characteristics which mark her distinction. Her physical nature with remarkable frequency possesses the same distinction, and is barren in a reproductive sense. The same law applies no doubt to men of genius also, and is explicable in the sense that you cannot both have your cake and eat it. External mental expenditure, if it may be so termed, when intense and complete, leaves nothing for internal transmission, and Galton's industrious work on 'Hereditary Genius' notwithstanding, genius is not hereditary. The exceptional female whose talents have given her a masculine equality, has only really unsexed herself, which is an instinctive acknowledgment that prepotency rests with the male. The ancient Greeks who through Plato and Aristotle gave us systems of logic and philosophy which denote the highest powers of reasoning, never doubted this ascendancy. "στῦλος ὄικου παιδές εἰσιν αρσενες" (Male children are the pillars of a house) was a dictum among them. So believed the Latin races, and so others. Pedigree everywhere is reckoned through the male, and this is no arbitrary proceeding but the instinct of circumstances, and the outcome of accumulated experience."

We are also reminded that "the testicle is a most delicately sensitive structure. A squeeze will illustrate this. That its sensitiveness is not purely local, but has a consti-

tutional effect, may be proven by the same means. Of its nerve-supply and the ganglionic nature of it, there can therefore be no doubt, and that it has a function beyond a merely local secretion of the male element there can be as little doubt, for it is evidenced by the mental change produced by castration. Similarly, the dementia noted to follow the loss of the ovaries in the female proves not only the loss of the tissue itself, but the loss of a contingent portion of the perfect organism, and one primarily and absolutely in touch with the sensorial functions."

In his final summing up the author tells us that, the immature ova and sperm-cells are simply latent germs minus those vital and dynamic conditions which mature them and constitute their activity after their conjunction, but which in the case of the male element have been fully impressed upon it prior to this union. With the beginning of maturity in the Graafian follicle begins the impress of the maternal characteristics upon the ovule, which continue until full maturity of the conception in the uterus—the conception and maternal organism being marked by a mutual and striking affinity. This is also evidenced even in nursing, as it is well known that excitement of the mother affects the nursling through the milk.

The spermatozoon, unlike the ovule, must be, and is, fully equipped at the moment of impregnation with all the characteristics of the male organism. The necessity of this special equipment is arranged for by a much more complex and detailed organ of reproduction in the male. While the female characteristics are conveyed to the ovule by the sympathetic system, they are continued to the ovum by the nutrition. In the male the paternal characteristics are conducted through a special ganglionic centre, and are impressed upon the spermatozoon during an elaborate and tedious transit through specially arranged tubing.

This ganglionic or reproductive nerve-centre in the male becomes active near the completion of growth, and its development is accompanied by those symptoms which mark the arrival at adolescence. At this period all roads lead to Rome, all thoughts lead to reproduction—until the function is established.

That the function is dependent upon an active and complete connection with an intelligent sensorium, is proved by the fact that male imbeciles are impotent, and also, I think, by the fact that imaginative and emotional races are the most prolific. Were the reproduction powers contained in the latent germ they would be independent of subsequent mental development. The fact also that diseases such as syphilis, contracted in adult life, affect the product of conception, and through it the mother, proves that the spermatozoon is very literally an up-to-date creation, and that it very fully represents a concentrated extract of the mature paternal organism. That the male element has an influence on the female organism over and above that of fertilization, is incontrovertible; her first impregnation has literally a double result; with the conjunction of the respective elements there develops a mutual product whose resemblance to the male organism would be infinitesimal, were its initial activities not potent enough to affect, and afterward modify, those of the mother.

Consequently the reproductive elements are latent germs in the first instance, which attain maturity by being charged with organic impressions from the parent, much after the manner of charging a phonograph with messages; which messages are liberated in the female system after meeting the suitable medium of the similarly, though not equally, charged ovule; or, to use another metaphor, if we consider the individual as a book, each spermatozoon is an index of the contents, but how printed, is a conundrum precisely on a level with how facts or ideas are recorded in memory, and we can conceive no material method for the performance of that function.

To append any further comments to this brilliant *résumé* would be to invite possible misconceptions, which must not be thought of in connection with paternal impressions.

PAIN, PLEASURE, AND ÆSTHETICS.

The physician is more apt to think of pain in connection with its avoidance by anæsthetics, than he is to associate it in any way with pleasure and æsthetics. It is with the psychology of pain that the author of a book fresh from the press of Macmillan & Co. has to do, and he treats of it together with its correlate pleasure, laying stress upon their special reference to æsthetics. In the first chapters the place which pleasure and pain should occupy in psychological classification is sought to be determined, as well as the relationship between them. The conclusion is reached that they must be looked upon as general qualities, one of which must, and either of which may, belong to any fixed element of consciousness. In the course of his examination the author further concludes that, we must assume the existence of an impulse within ourselves which leads us to produce results which have the power to attract others to us. This impulse might be identified with the art impulse. The reader will understand the trend of these preliminaries when, further along, the attempt is made to prove that all efforts to discover special qualities in beautiful objects which determine their beauty have invariably failed. The mental state of the observer of the beautiful in art and nature must be studied, and principles of unity sought on which to base the philosophic treatment of the subject. Æsthetics are considered as a branch of the science of pleasure and pain, but the author believes only those pleasures to be æsthetic which are permanently pleasurable in the memory. The æsthetic field is thought, therefore, to vary with different races and different individuals, and in the same individual at different times; changing with his change of conception as to what is worthy in the world surrounding him. To correct the individual taste it is necessary to recognize the standard of others, and to compare it with the taste of the educated and refined. It is futile to try to force our standard upon others.

Upon page 215 the author gives the basis for pleasure-pain phenomena. "Pleasure," he says, "implies use of surplus stored energy, while pain implies a subnormal reaction to a given stimulus." Pain, in other words, is determined by the reception of a stimulus to which the organ is incapable of reacting.

The author, Henry Rutgers Marshall, shows himself to be quite at home with this very intricate problem, and one's confidence is secured from the start by the thorough acquaintance displayed with the views of other writers. Even if one cannot accept all the theories, it will repay the reader for the difficulties in gaining acquaintance with the author's terminology, and some new ideas will be found advanced.

not recover, he will break down entirely. Dr. Schweninger has been called to Varzin to be present in case the condition of his illustrious patient should grow worse. Mr. Gladstone was recently operated upon for cataract. The young King of Spain is very delicate, though no definite disease has as yet declared itself. President Cleveland is reported to be suffering from malaria and the effects of overwork.

A Hospital for Consumptives is to be erected in Toronto, Canada, Mr. W. J. Gage, of that city, having made a contribution of $25,000 toward that purpose.

The Tri-State Medical Society, embracing in its membership the three States of Georgia, Alabama, and Tennessee, will hold its next annual meeting at the Kimball House, Atlanta, on October 9th, 10th, and 11th.

A Prize Essay on Tuberculosis.—The Colorado State Medical Society offers a prize of $100 for the best essay upon "The Diagnosis of Tuberculosis by Microscopic Examination of the Blood." The paper is to be of such a length that not more than thirty minutes would be consumed in its delivery. The name of the author must be kept secret. Essays in competition for the prize should be sent to Dr. Charles Denison, Denver, not later than April 1, 1895.

Miss Florence Nightingale is an honorary president of the Tropical Section of the International Congress of Hygiene and Demography, in session this week in Buda-Pesth.

Sunstroke.—Surgeon-major Martin recognizes three forms of sunstroke, viz.: The congestive or cerebro-spinal, the syncopal, and the pulmonary. In all these cases he says death appears to be due to the absorption and non-elimination of the toxines or leucomaines produced in excess by great muscular fatigue, and which rapidly poison the system. This toxic saturation of the body is facilitated by damp heat and stormy weather as much as by insolation properly so called. When, in spite of precaution, a soldier is attacked, he must be at once taken to a shady or cool place, his clothes loosened so as to facilitate breathing, artificial respiration should be practised, while an assistant at the same time produces corresponding compression over the body. While artificial respiration is being performed the head of the sufferer is covered with a cooling bandage, sinapisms are applied to the lower limbs, and a subcutaneous injection is given every hour of one Pravaz syringeful of ether. In the syncopal or pulmonary form, in which the nervous system is prostrated, it is better to give injections of caffeine, as much as a gram in the twenty-four hours, and in the congestive form, while cold affusions are applied to the head and sinapisms to the extremities, to give subcutaneous injections of pilocarpine to produce profuse perspiration; and then to aid in the elimination of the toxines purgative enemata must also be given.—London Correspondence of the *American Practitioner and News.*

Quack Nurses.—Quackery is contagious and widespread. There are quacks not only in medicine, but the infection seems also to have invaded the profession of nursing. From Detroit comes the announcement of the organization of a "Correspondence School of Health and Hygiene," which proposes to give "instruction by the correspondence method in the care of the sick." The course of instruction, it is believed, "if thoroughly studied by a reasonably intelligent person, will render the pupil as truly a trained nurse as the great majority of those who come from the training schools. . . . No previous training or study is required other than the ability to read and comprehend." As to age, sixteen is not considered too young nor fifty too old. It needs scarcely be said that the art of nursing is not to be acquired by correspondence, from reading, or even from didactic lectures; these measures may aid in the comprehension of the principles upon which intelligent and rational nursing is based, but actual experience by the bedside, in the hospital-ward, and in the sick-room, is absolutely essential.—*Medical News.*

Large Families do not seem to be so very rare even in these latter days. We recently referred to the fecundity of Canadian women, and now England comes to the front with large families. A London family paper not long since offered a prize of one guinea to the woman subscriber who could prove that she had the greatest number of children. The prize was divided between two women, each of whom had twenty-five children. The first sixteen women entered on the list of competitors had a total number between them of two hundred and eighty-eight living children.

Diphtheria Antitoxin.—At a late meeting of the Berlin Medical Society Dr. Baginsky criticised rather unfavorably the report of the antitoxin treatment of diphtheria made at a previous meeting by Katz, to which we referred in a recent issue. He said that the credit of the discovery was due to Bogola, of Sienna, who first made in-

oculations of a diphtheritic material in 1868. Analyzing Katz's report, he said that of 128 cases only 14 died, and from these deaths those attributed to scarlatina, septic poisoning, etc., were eliminated, leaving a mortality from the disease or the drug of only about thirteen per cent. But, if the same process of elimination was carried out in cases treated by the ordinary methods, he believed that the difference in favor of the new mode would be found to be very slight, if indeed there was any.

The Mortality of European Cities.—The annual death-rate per 1,000 of the following cities, as computed for the returns for the first week in August, is: Paris, 19; Brussels, 19; Amsterdam, 12; Rotterdam, 17; The Hague, 15; Copenhagen, 15; Stockholm, 15; Christiania, 16; St. Petersburg, 62; Moscow, 43; Berlin, 19; Hamburg, 19; Dresden, 19; Breslau, 33; Munich, 26; Vienna, 23; Prague, 24; Buda-Pesth, 25; Trieste, 30; Rome, 16; London, 17; Liverpool, 27; Birmingham, 14; Manchester, 21; Dublin, 20; Edinburgh, 14; Sheffield, 18, and Swansea, 10. The excessive rate for the Russian cities is due largely to the epidemic of cholera.

Boracic Acid.—The greater part of the crude boracic acid imported into England comes from Tuscany, in the immediate neighborhood of Castelnuovo. It is originally dissolved in the waters of an underground hot lake, which sends off steam charged with about three per cent. of boracic acid through many openings, called "fumerolles," on the surface. The steam is condensed, and the acid dissolved in fresh water, from which it is crystallized in tubs. The acid is then packed in casks and shipped from Leghorn to England, where it is refined into the pure pulverized boracic acid familiar to our readers.—*Medical Press.*

A Medical School for Women is about to be established in St. Petersburg under Government auspices. A similar institution was organized through private initiative a number of years ago, but was soon closed by the authorities, and since that time the Government has always frowned upon the higher education of women.

Professor Josiah Parsons Cooke, Professor of Chemistry at Harvard, died at his summer residence at Newport, on September 3d. He was sixty-seven years of age. He was graduated from Harvard in 1848, and had been connected with the University in a teaching capacity since 1850.

The Eighth International Ophthalmological Congress was held in Edinburgh during the first week in August, under the presidency of Dr. Argyll Robertson. Drs. Henry Power and Swanzy were elected vice-presidents, Dr. Berry, general secretary, and Drs Parent, Hess, and Fergus assistant [illegible]. The honorary presidents

the seventh Congress was held in Heidelberg in 1888. In Donders he said had been lost one of the greatest ornaments of the world of science, and in Becker the ophthalmological world had lost an able surgeon whose discoveries in the anatomy and pathology of the lens were classical. He referred also to the absence of Helmholtz,

A Cattle Quarantine Station.—All horned cattle, sheep, and swine imported into this country must be kept in quarantine for a period until all danger of the development of tuberculosis, pleuro-pneumonia, foot-and-mouth disease, anthrax, or hog cholera has passed. The period of quarantine for cattle is ninety days, that for sheep and swine fifteen days. The Government provides the quarters for the animals free of expense to the owners, but the latter must pay for the transportation of the animals to and from the station, and for their keep when there. There are stations of this kind at several places along the coast, but the most important one is at the Garfield Farm, near Passaic, N. J.

The Dangers of Thyroid Extract.—Dr. W. D. James reports in the June number of the *British Journal of Dermatology* a case of glycosuria caused by thyroid extract given for the relief of psoriasis. The patient was a medical man, had taken the extract in small doses for some time without effect upon the disease, and then increased the dose quite suddenly. At the end of a week he began to suffer severely from depression, with frequent flushings and palpitations. The nervous symptoms increased, and the patient felt and looked a very old man. Before another week elapsed his thirst became unquenchable; the quantity of urine greatly increased, the breathing became embarrassed, the pulse rose to 132 per minute, and the smell of acetone was detected in the breath. The urine had a specific gravity of 1.032, and sugar was freely found by all tests. The thyroid treatment was at once stopped, and antidiabetic diet adopted, with the result that the quantity of sugar decreased daily, and disappeared entirely in a few days. No improvement was noted in the psoriasis.

A Definition.—A London daily paper explains to its readers the term "exploratory incision," which, it says, "means quarrying into a patient on the chance of discovering some disease in an internal organ which is curable by its removal."

Reviews and Notices of Books.

INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY. Vol. XV. Washington, Quarto, pp. 842. Government Printing Office. 1894.

VOL. XV. of this well-known series is somewhat smaller in bulk than its predecessors. Its contents are from Universidad—Vzoroff, and covers 6,152 author titles, representing 3,312 volumes, and 4,235 pamphlets. It also includes 8,596 subject titles of separate books and pamphlets, and 35,667 titles of articles in periodicals. Its editor and compiler, DR. JOHN S. BILLINGS, still has charge of the work, and is to be congratulated on its approaching completion.

WEEKLY ABSTRACTS OF SANITARY REPORTS (1–52), vol. viii.

THE volume contains the voluminous weekly reports of the Supervising Surgeon General of the Marine Hospital Service for the first half of the year 1893, has 1,300 pages of contents, and is of value chiefly to the sanitarian and statistician in need of official data.

BURDETT'S HOSPITAL AND CHARITIES ANNUAL, 1894, being the Year Book of Philanthropy. Fifth year. By HENRY C. BURDETT. London: The Scientific Press, Limited. New York: C. Scribner's Sons.

THIS useful volume is replete with information regarding the charities of the English speaking world, and notwithstanding its nearly six hundred pages is a marvel of condensation. It touches upon almost every subject in which philanthropy is concerned; it discusses philosophical problems, character and cost of work done, sources of revenue, as well as directs into proper channels the contributions of that very large class who disburse in a perfunctory way a moiety of their income, without the least care for its destination. A paragraph upon the professional philanthropists, who live on their share of the subscriptions, well portrays an aberrant species not unknown even in our millennial hemisphere. The groupings of hospitals, asylums, homes, and orphanages are admirable, and constitute a *coup d'œil* as searching as comprehensive. In fact, in this annual, besides the enormous labor bestowed upon its compilation, about which the general reader takes but little thought, there is a wealth of texts capable of being amplified into many sermons. To say the least, the author has made an encyclopædic addition to a much needed literature for the physician who looks beyond the mere emoluments of his profession.

THE TRUTH ABOUT HOMŒOPATHY. By DR. W. H. HOLCOMBE. Philadelphia: Boericke & Tafel. 1894.

THIS is a posthumous manuscript which is a defence of homœopathy. Although it contains no new argument, it is well written, and as such may be considered a desirable addition to the class of literature to which it belongs.

ANNALES DE L'INSTITUT DE PATHOLOGIE ET DE BACTÉRIOLOGIE DE BUCHAREST, publiées par VICTOR BABES, Professeur à la Faculté de Médecine et Directeur de l'Institut. Deuxième Année, 1890. 4to, pp. 506. Bucharest, 1893.

THIS handsome volume is the third part of the "Annals of the Institute of Pathology and Bacteriology of Bucharest," and contains the papers published from that laboratory during the year 1890. Thirteen papers in all are included, the majority of which are here given in both the French and Roumanian languages. All have appeared before in different medical periodicals; they are here collected for convenience of reference. Among them are three papers on glanders and its bacillus, one on scarlatinal nephritis, two on the association of bacteria in the production of disease in general, and of the lesions of tuberculosis; three on different phases of tuberculosis, including the results of treatment of lupus by tuberculin, and an exhaustive paper on the different forms of the plasmodium malariæ. Many of the papers are handsomely illustrated by colored plates.

TRANSACTIONS OF THE NEW YORK STATE MEDICAL ASSOCIATION, for 1893, vol. x. Edited by E. D. FERGUSON, M.D, New York. 8vo, pp. 585.

THIS volume contains the usual variety and number of valuable communications from its talented contributors, and is in every way the equal to any of the former editions, which is saying all we can in its praise. The frontispiece is an excellent portrait of the late Dr. A. L. Carroll, one of the founders of the Association, whose obituary by Dr. Gouley is a model of its kind and well befitting the subject. A very comprehensive decennial index also adds to the value of the volume.

THE PRACTICE OF MEDICINE. By EDWIN M. HALE, M.D., author of "New Remedies," "Diseases of the Heart." Emeritus Professor of Theory and Practice, Chicago Homœopathic Medical College, etc. 8vo, pp. 1018. Chicago: Gross & Delbridge. 1894.

THIS work, which is very complete in its way, is intended more especially for practitioners of homœopathy, although it has a strong liberal tendency toward what the author styles the old school of practice. The author is certainly very liberal in his views, refreshingly dogmatic in his condemnations, and emphatically positive in drawing the line between what is and is not tenable in the present accepted doctrines of disease. There is no mistaking what he means when he gives the results of his personal experience in "proving" and in the ultimate results of treatment. The reader everywhere in the text finds the different drugs, of large and small degree, in strange relations with each other, that are hardly explainable on the score of a compromising liberalism as to their respective actions. With a laudable effort to reconcile treatment to the latest discoveries in bacteriology, he is hardly consistent in his attempt to explain the action of germicides with the doctrine of similia similibus curantur. The task is professedly a difficult one, and he makes as good a showing as is possible under the circumstances. His descriptions of the clinical phenomena of disease are terse and to the point, and are made especially interesting by numerous historical references not usually found in similar works. The chapters are short, the subjects numerous, and their discussion interesting and suggestive. The frontispiece, which is the only illustration in the work, gives an excellent likeness of the author with his autograph.

Medical Journals not Appreciated.—The following reply was returned to a circular letter soliciting subscriptions to a certain medical journal:

FARIBAULT, MINN.

Your Copy of the ——— Jurnal come, and the letter to—askin me to send fifty cens and git it fur a yeer. I don't nead no jurnals. When I git a tuff case I go off inter sum secrit plase and tell the lord all about it and wate for him to put inter my minde what ter do. That's bettern jurnals and syklopedes and such. If we hed more lord trustin docters and less colleges weed fare better. The lord noes morn all the doctors and if we go to him fur noledge it ill be bettern jurnals.

Fraternally in the lord,
A CHRISTUN DOCTER.

P. S.—I've practist medisen morn fifty yeers. Yore ken publish this letter if you want ter.—*Northwestern Lancet.*

Royal Ladies who Smoke.—A census has been taken of the cigarette-smokers among the ladies of the courts of Europe, and it has been found that the majority of them indulge more or less openly. Among them are the Queens of Italy, Spain, and Portugal, the Czarina, and the Empress of Austria.

Society Reports.

CANADIAN MEDICAL ASSOCIATION.

Twenty seventh Annual Meeting, held in St. John, N. B., August 22 and 23, 1894.

(Special Report for the MEDICAL RECORD.)

DR. T. T. S. HARRISON, of Selkirk, Ontario, the President of the Association, called the meeting to order, and introduced several delegates from foreign medical societies. Among these were Dr. L. Duncan Bulkley, of New York, delegate from the American Medical Association, and Dr. Jonah, of Eastport, from the Maine Medical Society. Drs. Charles O'Reilly, I. H. Cameron, and J. E. Graham, delegates of the Ontario Medical Association, were also present. A large number of new members, chiefly from the Maritime Provinces, were admitted. Letters of regret were read from Sir Charles Tupper, Drs. Osler, Marcy, Bray, Mullin, and McLean.

Epilepsy.—DR. HATTIE, of Halifax, read a paper with this title, dealing chiefly with theories concerning the etiology of the affection. He gave an extended report of certain experiments and of the post-mortem changes that he had observed. These changes, however, he thought might be rather the result of the nerve storm than the cause of it. The most probable cause lay in the action of some toxic irritant, itself the product of some systemic disease. Anæmia is present in most cases of epilepsy, and the speaker thought that this might possibly be the condition upon which the disturbance depended. On the supposition that the poison might be absorbed from the intestinal tract, he had administered intestinal antiseptics in conjunction with the bromides, and, comparing the number of paroxysms occurring under this method of treatment with the number observed when the bromides alone were administered, he was led to the conclusion that there was at least a modicum of truth in his assumption. Under the new method there was a very marked diminution in the number and frequency of the attacks.

The paper was discussed by Drs. Cameron, of Toronto, and Wright, of Ottawa.

Antagonism of Erysipelas and Tuberculosis.—DR. MUIR, of Truro, reported a case of tuberculous disease of the arm which had been cured by accidental infection with erysipelas. The patient was a woman, thirty-nine years of age, who had suffered from well-marked and typical tubercular ostitis of the arm for fourteen years. Examination of the discharge from the sinuses showed the presence of the tubercle bacillus. The sinuses were opened and scraped and an iodoform dressing was applied, but little or no improvement followed the operation. Five weeks later the wound became accidentally infected with erysipelas. The patient was very seriously ill for some time, but finally made a good recovery from the erysipelas, soon thereafter it was observed that the original trouble was improving, and in a comparatively short time the tuberculous disease was entirely healed. The speaker exhibited some photographs showing the condition after the attack of erysipelas.

Presidential Address.—The subject of the President's address was, "My Experience and Observation in the Practice of Medicine Extending over Half a Century." The address dealt chiefly with the clinical signs and treatment of the various diseases commonly met with among the early settlers in the woods, of the more usual domestic remedies employed by these pioneers, and of the difficulties and hardships of the medical practitioner in those days. He referred also to the fact of the disappearance of miasmatic diseases and murrain since the country had been extensively cleared up and drained, and dwelt upon the problem as to how and by what means the specific germ-diseases were introduced into a new country. He did not believe that the specific causes could originate *de novo*, yet it was often difficult or impossible to say whence they came. The latter portion of the address was devoted to a discussion of the matter of inter-provincial registration, which he favored, and which he thought it was in the power of this Association to bring about.

A vote of thanks was moved by Dr. Bayard, of St. John, seconded by Dr. Hingston, of Montreal, and carried with much enthusiasm. Dr. Wright, of Ottawa, moved, and Dr. I. H. Cameron, of Toronto, seconded, that a committee be appointed, representing the various provinces, to consider the suggestions made in the President's address, in relation to the question of inter-provincial reciprocity in medical practice.

Appendicitis.—DR. JAMES BELL, of Montreal, read a paper with this title, which was based upon the results of his work in the Montreal General Hospital during the past eleven months. He had had forty eight cases, of which forty were operated upon; all of the patients, both those operated upon, and those treated expectantly, recovered, except three. The speaker believed that all cases of appendicitis should be in the hands of the surgeon from the beginning of the attack, and in the majority of instances an operation should be resorted to as soon as the diagnosis was definitely established.

DR. HINGSTON, of Montreal, discussed the question from the conservative side. He had prevented the operation, he said, about thirty times, and only in one case did he regret that he had not counselled the surgical intervention. He did not want the younger members of the Association to go away with the idea that operation was the first thing to be thought of in every case of appendicitis they might have. They could not argue from the results of Dr. Bell's cases, for in the first place Dr. Bell was an able and experienced surgeon, and in the second place the cases that came under his care were for the most part of a very serious character and really calling for operation.

SIR JAMES GRANT, of Ottawa, reported two cases he had had which seemed at first to be fit for operation, but one was in a gouty and the other in a rheumatic subject. He did not operate, and both cases recovered. He did not believe that the cause of the inflammation in these cases was the presence of a foreign body in the vermiform appendix.

DR. SHEPHERD, of Montreal, pointed out that the surgeons always got the worst cases, so that it was difficult from a comparison of statistics to determine just what was the proportion of cases which should be operated upon and how many should be treated by medical means. His idea was, as a rule, to operate after the acute attack had subsided. He thought that the tender-point of McBurney should be referred not to the appendix but to the inflamed condition of the mesenteric glands, for the appendix might be found on the right side, in the pelvis or up under. Strange was in favor of non-interference until the presence of pus could be made out. He had usually refrained from operating during the acute stage, and had never had cause to regret it.

DR. CAMERON, of Toronto, said he followed Treves in this matter; wait until pus forms, then open and drain. He thought that it would be unfortunate if the experience of a hospital surgeon of skill should be permitted to determine the matter one way or the other.

DR. BELL, in reply, said that it was conceded by all that no man could say definitely just when to operate in all cases. Out of the forty cases in which he had operated there was perforation in thirty-two; in three the appendix was gangrenous, in two it was bound down by adhesions; in three other cases the symptoms pointed to very grave inflammation, yet no abscess was found and the gut was not perforated. He used to follow the expectant plan, and his losses were much greater than now. The most extreme mortality after these operations is two or three per cent. If the patients were let alone, perforation and collapse might occur at any moment. The very mild, or rather short, cases in which all the symptoms

passed away within twelve hours, need not be interfered with, for they were probably cases of cæcitis. He believed that the method advocated by Treves was not according to the principles of true surgery.

Eye-strain Headaches.—Dr. Morrison, of St. John, read a paper with this title. These headaches had been treated by tenotomy, but this was dealing with the effect only and not with the cause; the operation relieved some of the reflex troubles for a time, but the ultimate result was not good. The real trouble was an imperfect curvature (it might be very slight) of the cornea. This condition added to the work of the delicate muscles of accommodation, when much near work was to be done with the eyes, and overtaxed the ciliary muscle, from which resulted the distressing reflex headache. The pain was usually situated in the neighborhood of the temples, but sometimes extended to the occiput and down the back of the head. Numbness sometimes occurred in other parts of the body, and digestive disturbances were likewise at times a marked symptom. A proper correction of the myopia, hypermetropia, and astigmatism, together with the administration of tonics, removed the insufficiency. The speaker reported some of the cases of headache that he had been called upon to treat, where the proper management of the trouble had been neglected because no examination of the eyes had been made. The muscle would recover just as a sprained limb would if properly treated. The use of suitable glasses was a crutch for the over-strained ciliary muscle.

Diseases of the Ovaries and Fallopian Tubes.—Dr. Lapthorn Smith, of Montreal, followed with a paper on the treatment of diseases of these organs. The subjects of gonorrhœal and tuberculous salpingitis, tumors of the ovaries, and ovarian congestion were dwelt upon, their most prominent symptoms pointed out and their treatment sketched. Many cases were reported and numerous pathological specimens shown.

Influence of the Mind Upon the Body.—Dr. Bayard, of St. John, delivered the Address on Medicine, taking this as his title. He gave a brief résumé of the general anatomical and physiological features connected with the nervous system, and pointed out that various mental phenomena were causative of marked changes in the body, particularly in respect to the action of the vasomotor nerves. He had known pain to disappear in the presence of sudden danger, and he quoted Hunter as saying: "My life is at the mercy of any scoundrel who chooses to put me in a passion," and, strange to say, that was the cause of his death. It is believed that the elaboration of the blood constituents is interfered with when the individual is under emotional excitement. The speaker then discussed many of the various nervous troubles so common at the present day, and suggested methods for their treatment.

In connection with one of the points referred to in the address, Dr. Bayard moved, and Dr. Hingston seconded, that in the opinion of the Association, the system of education generally pursued in the Dominion of Canada draws too largely upon the brain-tissue of children, and materially injures their mental and bodily health. It was objected that this resolution was too sweeping in its wording, and that there was no suggestion as to what department of the school system was at fault, nor as to what portion of the Dominion the strictures more especially applied. Our young people, Dr. Cameron said, were not suffering from too much education, neither were their elders for that matter. The educational system had been the subject of the best thought of the best men in the country, and he believed the motion was altogether too condemnatory. A resolution was than passed that the matter be referred to a committee, consisting of Drs. Powell, Hingston, Graham, and Bayard, to report at the next meeting.

Functional Hepatic Disorder.—Dr. J. E. Graham, of Toronto, presented a communication entitled "Some Functional Derangements of the Liver," in which he reviewed the history of the physiology and pathology of the liver, and showed that there are other and no less important functions of the organ than the secretion of bile. He outlined the work of the liver and demonstrated the very important functions that it has to perform in the human economy. Its importance as a blood elaborating and fat-forming organ in the fœtus must be great, since we know that it is equal in weight to all the rest of the body at the end of the first month, in the proportion of one to three at the end of the third, and of one to sixteen at the end of the fifth month. The speaker then discussed the question of "hepatic inadequacy," a condition induced by the action of certain poisons upon the hepatic cells. The hepatic cells stored up the glycogen until it was needed by the economy, and when this function was impaired various clinical phenomena were observed. As regards the treatment of "biliousness," the exact cause of this condition should be searched for and found, if we were to hope for success in relieving the trouble. The diet should be most carefully attended to; starchy foods should be absolutely forbidden, but milk, because of its ready assimilation and diuretic action, should be regarded as of great value. The reader recommended certain forms of exercise as of value in assisting the circulation. Massage over the gall-bladder, as promoting the egress of bile, is helpful, and free purgation is essential. He then discussed the various drugs used in hepatic disorders, calomel, euonymus, podophyllum, etc., and their several indications. When the elaboration of urea is incomplete, treatment directed toward an increase of metabolism—massage, bathing, the drinking of mineral waters, etc.—is to be recommended. The great point to aim at is to secure and, if possible, restore the integrity of the hepatic cells.

Brain Operations.—Dr. Hingston, of Montreal, reported four cases of brain operation, two of which were for epilepsy. One was for the relief of paralysis of certain muscles of the arm in a young man who had received an injury to the skull some twenty years before; there was also spasm of some of the muscles of the face. The operation afforded almost complete relief. The speaker employed a trephine two inches in diameter, which he contended was much superior in some respects to those in ordinary use and of smaller size.

Amputation at the Shoulder-joint.—Dr. Shepherd, of Montreal, related the history of a case in which he had removed the entire upper extremity for a chondro-sarcoma involving the shoulder joint, and another of removal of a large enchondroma of the pelvis. The first operation had been but seldom performed, this being the first that was on record as having been done in Canada.

The paper was discussed by Drs. Hingston, Cameron, and Steves.

Prevention of Tuberculosis.—Dr. Inches, of St. John, read a paper with this title, in which he advocated the necessity of increased activity on the part of the profession, the public, and the government in dealing with this disease. The patients themselves needed much instruction in regard to the disinfection of sputa, so as to lessen the danger to others in the house. Even in well-kept consumption hospitals, he said, there is some danger of infection. He dwelt upon the difficulties connected with notification, registration, and isolation. He had found it very difficult, even among his wealthy patients, to secure isolation and fresh air, and of course it is infinitely more difficult to secure such among the poorer classes, who are often not in position to carry out the necessary measures looking to this end. The speaker held that special sanitaria should be established, so that every patient who could not be properly looked after at home might find a place where his necessities could be attended to.

Treatment of the More Ordinary Skin Diseases.—Dr. L. Duncan Bulkley, of New York, read an interesting paper on the treatment of skin diseases by the general practitioner. He said that there were really only a few skin diseases that made up the bulk of those coming under the care of the general practitioner, and if we learned to

diagnose and treat these we should be in position to cure the greater number of diseases of the skin; the few rare cases could be sent to a specialist. He urged the necessity of paying more particular attention to each individual case, and of not treating all alike because they had a disease with a common name; routine should be avoided, and careful inquiry should be made into every detail of the patient's system and habits. The history of the eruption, and of former eruptions, the family tendencies as to the presence of asthma, rheumatism, etc., should all be made the subject of painstaking inquiry. If the general practitioner were well acquainted with acne, eczema, and syphilis, he would be able to treat satisfactorily the majority of cases of skin diseases that came under his care. As to eczema, too much was often done—the disease was over treated. He had grown more and more convinced of the great necessity of constitutional treatment in all these cases of skin affections, and had often had occasion to observe that the correction of some fault in diet or mode of life was sufficient to effect a cure. The speaker further emphasized some of the more important points to be observed in the treatment of acne, syphilis, psoriasis, and urticaria.

The Contagiousness of Tuberculosis.—Dr. J. F. Macdonald, of Nova Scotia, read a paper with this title, in which he advocated the bringing of the matter of the contagiousness of this disease before the people through the medium of the public press. He favored a system of registration, careful disinfection, government inspection of infected places, the establishment of sanitaria, and the enactment of laws to hinder the infected from spreading the contagion.

Nasal Cauterization.—Dr. Kirkpatrick, of Halifax, presented a communication on the subject of cauterizations of the nasal mucous membrane, in which he uttered a warning note against the indiscriminate introduction of strong caustics into the nasal cavity. He had seen entire destruction of the membrane and other serious consequences follow an abuse of these remedies, which were, however, of such exceeding value when properly and judiciously employed.

Other papers read were: "Adhesions of the Soft Palate, and their Treatment," by Dr. Hamilton, of Montreal; "The Present Status of Asthenopia," by Dr. Buller, of Montreal; "Hysteropexy," by Dr. K. N. Fenwick, and "A Medico-legal Romance," by Dr. Steves, of St. John.

After the customary votes of thanks, the meeting was closed by the President. It was decided to hold the next meeting of the Association in Kingston, Ontario.

Typhoid Fever and Vaccination.—Doctor William Finder observed that after typhoid fever patients recover they are very susceptible to vaccination. This observation has been verified many times during a number of years, and the writer suggests that others confirm or disprove the theory. So satisfied is Dr. Finder with the correctness of the observation, that he now revaccinates his typhoid patients as soon as they recover from the fever.—*Medical News.*

Erysipelas Toxins in Malignant Disease.—The following are the conclusions of Dr. William B. Coley, in an article on this subject in the *American Journal of the Medical Sciences* for July, 1894: 1. The curative action of erysipelas upon malignant tumors is an established fact. 2. This action is much more powerful in sarcoma than in carcinoma. 3. This action is chiefly due to the toxines of the erysipelas streptococcus, which may be isolated and used with safety. 4. This action is greatly increased by the addition of the toxines of bacillus prodigiosus. 5. The toxines, to be of value, should come from virulent cultures and should be freshly prepared. 6. The result obtained from the use of toxines without danger are so nearly quite equal to those obtained from an attack of erysipelas, that inoculation should rarely be resorted to.

AMERICAN MEDICAL ASSOCIATION.

Forty-fifth Annual Meeting, held in San Francisco, Cal., June 5, 6, 7, and 8, 1894.

(Continued from Vol. 45, page 799.)

SECTION ON PRACTICE OF MEDICINE.

THIRD DAY, THURSDAY, JUNE 8TH.

Typhoid Fever.—Dr. John Eliot Woodbridge, of Youngstown, O., read a paper on this subject in which he claimed that typhoid fever, if a germ disease, and of this he felt confident, could be aborted. The disease was, he said, on the increase, and was limited by no geographical lines. The author claimed that he could cure every case of typhoid fever if he saw it early enough. Treatment by means of antiseptics such as thymol, guiacol, eucalyptol, etc., was the course pursued by him in these successful cases.

Diagnosis and Treatment of Diseases of the Stomach by the Stomach-Tube.—Dr. A. W. Perry, of San Franciso, Cal., stated that most disorders of the stomach depended upon fermentations or abnormal accumulations in quantity or quality in that organ. The fermentations were acetic, lactic, butyric, cellulose, etc. Lactic-acid fermentation develops normally within fifteen to twenty minutes after digestion commences, but is held in check by the hydrochloric acid of the gastric juice. Acetic and butyric fermentations are prevented by a more rapid and complete emptying of the stomach. By means of the stomach-tube we can determine dilatations, and determine the chemical composition of the stomach contents. Spasm of the glottis may interfere with the introduction of the tube. To overcome this the speaker is in the habit of touching the back of the pharynx with his finger. Cocaine may be used. In some cases the circular fibres of the œsophagus contract and thus obstruct the passage of the tube. Reflex spasm of the glottis is the obstacle in the greater number of cases. The stomach-tube should be used only every other third or fourth day. During the intervals the internal administration of an antifermentative is recommended. The speaker uses resorcin, gr. v., after meals, and finds this does not interfere with the digestive processes. The use of the stomach-tube will prove valuable in the diagnosis of cancer and ulcer of the stomach, by allowing a quantitative test for hydrochloric acid.

The author finds lavage of benefit in the treatment of the following stomach disorders: Acute and chronic gastric catarrh, dilatation of the stomach, not dependent upon pyloric stricture, various fermentations, causing reflexes, cancer, ulcer, and finally in obstinate singultus.

Dr. Freeman, of Indiana, commended the paper and suggested a method to render the œsophagus tolerant. In his experience he found that by the frequent use of the œsophageal bougie between the acts of lavage the œsophagus established a tolerance of the tube.

The Law of Equivalence in Medical Science.—Dr. R. W. Murphy, of San Francisco, Cal., expressed the belief that before many years have passed prophylactic measures will be discovered for such diseases as Bright's disease, cancer, tuberculosis, etc., as has already been the case with the small-pox, hydrophobia, etc. He called attention to the great diversity of treatment directed toward the same disease, and believed we should have more practical text-books and drug action, both as regards maximum and minimum dosage.

He predicted that the physician of the future would be the man who closely watches the dual action of his drugs. In the case of calomel, cited as an instance, we may find physicians recommending a dosage varying from $\frac{1}{20}$ grain to 60 grains for the same disease and under apparently the same conditions. The same may be said regarding almost all of the drugs in use.

Among other remedial agents electricity is largely employed without thought of the law of equivalence. Experiments should be a thing of the past.

The following papers were read by title: "Cham-

pagne and Strychnine in Chest Troubles of the Aged," by Dr. Edward Buxton, of National City, Cal.; "The Treatment of Erysipelas," by Dr. James M. Anders, of Philadelphia, Pa.; "The Use of Turpentine in the Treatment of Diphtheria," by Dr. E. W. Kellogg, of Milwaukee, Wis; "Lung Gymnastics in the Treatment of Chronic Disease," by Dr. L. P. Walbridge, of Decatur, Ill.; "A Clinical Study of Scarlatina at High Altitudes," by Dr. J. N. Hall, and Dr. William P. Munn, of Denver, Col.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 25, 1894.

GEORGE C. FREEBORN, M.D., PRESIDENT, IN THE CHAIR.

Abnormalities of the Heart.—DR. L. PEARCE BAILEY presented two specimens showing abnormalities of the heart. The first one showed a fourth cusp to the aortic valve, and also some vegetations. The second specimen was from a child who had died at birth from prolapse of the umbilical cord. A fibrous cord was found stretched across the aorta.

Primary Thrombosis of the Pulmonary Artery.—DR. GEORGE P. BIGGS presented specimens of the above. A man, forty-seven years of age, had been brought to the New York Hospital in a bad condition, supposed to be suffering from pneumonia. No history was obtainable, and he died a few hours after admission, and without a careful record of the case having been made. At the autopsy the first feature of interest observed was a great depression of the diaphragm, especially on the left side. On the right side it was at the fifth intercostal space, and on the left at the eighth intercostal space in the mammary line. It had pushed the spleen down until its upper border was on a level with the upper border of the left kidney. From the left pleural cavity 1,200 c.c. of a greenish serum had been collected, and this fluid was found to contain fibrin in considerable quantity. The heart was so much displaced as to be almost entirely to the right of the median line. The entire left lung, with the exception of the upper half of the upper lobe, was compressed by this fluid. The pleura was thickened and in the recent state was covered with fibrin. There was no evidence of a recent tubercular process in the lung itself, or in the pleura, except at one point—a small cheesy nodule in the parietal pleura. On scraping this and staining it, it was found to contain a large number of tubercle bacilli.

The pleurisy, the speaker said, was probably of tubercular character, although the lesions of tuberculosis in the lung appeared to be all of a chronic character. The lung of the opposite side was poorly aërated. There were a number of adhesions at the apex, and in the upper half of the upper lobe were a number of pigmented fibrous cicatrices with small cheesy areas scattered through it. The pulmonary artery going to the lower lobe contained a large ante-mortem thrombus, which was rather soft, but distinctly adherent to the vessel wall just beyond the origin of this branch from the main pulmonary artery of that side. The pulmonary tissue supplied by this vessel was very much congested, but was not œdematous, and there was consolidation. The thrombus seemed to have almost entirely occluded the lumen, but the usual effects of thrombosis were not very well marked. The heart was not nearly as much dilated as one would have expected with such extensive impairment of the lungs. The valves were normal except for slight atheromatous patches near their bases on the left side. The coronary artery showed quite marked atheroma, especially near its origin. The muscle of the heart appeared to be perfectly normal. There were no other lesions of importance. The pericardium was not affected.

The speaker said that the first case of primary thrombosis which he had presented to the Society was thought to be very unusual, and some of the areas were thought to be pneumonia. He was sure that the case just presented was the fourth of the kind that he had seen this winter, in which all possible sources of emboli had been sought for, yet none found. One of the other cases was quite similar to this one, the opposite pleural cavity being filled up with fluid. From the appearance of the organs in this case at the autopsy, it was not evident why it should have resulted in this way, except that the fluid had been allowed to remain so long that it had interfered with the action of the heart and the circulation in the opposite lung, thus causing death.

Small Round-cell Sarcoma of the Ovary.—THE PRESIDENT presented the half of a sarcomatous ovary which had been removed from a married woman, twenty nine years of age, who had had one child five years before. The tumor was supposed to have begun its growth shortly after the birth of the last child, four and a half years ago. It continued to grow until it measured 16 x 12 ctm., and weighed 1,100 gm. If this history were reliable, it would seem to indicate a very slow growth for a small round-cell sarcoma.

Sarcoma of the Ovary.—The President also presented a sarcoma of the ovary engrafted on an ordinary cyst-adenoma. The specimen had been removed from a woman forty five years of age, who had had five children, the last one fourteen years ago. This tumor had been first noticed nine years ago. She had suffered from flooding at intervals up to one year ago. The tumor had remained about the same size until two months ago, when it had suddenly began to grow very rapidly. At the time of the operation it measured 26 x 13 ctm. On close examination the central portion of the tumor was found to be made up of an ordinary cyst-adenoma, and small cysts filled with colloid material. Around the periphery was a sarcomatous mass—a mixture of small and large round cell sarcoma in which the large cells seemed to predominate, and the stroma was rather scanty.

The speaker said he thought it had been an ordinary cyst-adenoma up to the time when the growth had become so rapid, and that at this time the sarcomatous degeneration had begun. Probably, if the tumor had been left alone the whole mass would have been converted into a sarcoma. This was one of the first well-marked examples of sarcomatous degeneration that he had met with. He had examined upward of 1,000 ovaries, and out of this number had found only from five to seven sarcomata.

DR. GEORGE P. BIGGS referred to one case of large cystic tumor of the ovary which he had seen, in which, from the gross appearance, it was thought to be multilocular cyst, but on microscopical examination it had been found to be distinctly made up of sarcomatous tissue, as if a change had begun to take place in it similar to that found in the specimen just presented.

DR. FREEBORN said that on a previous occasion he had presented, in connection with a large series of ovarian tumors, one other specimen of sarcomatous degeneration. It was a multilocular cyst which had been reduced to three main cysts. On microscopical examination the septa of these cysts had proved to be sarcomatous.

DR. S. T. ARMSTRONG said that the only case he had seen was in 1880, in the female hospital in St. Louis. The patient was an unmarried woman who had been previously confined in an insane asylum for acute mania for three years. No abnormal condition connected with the ovary had been found. She recovered from the mania, and finally entered the hospital in a wretched condition. She died shortly afterward.

DR. THOMAS H. MANLEY said that solid tumors of the ovary were sometimes carried for years with but little inconvenience except that due to weight, and he was familiar with a few cases occurring in those past the menopause, in which there was no question about a reduction having taken place in the size of the growth, and having been accompanied by an amelioration of the symptoms. He would ask whether this sarcomatous degeneration was to be regarded as a malignant change,

or rather as a process whose object was to hasten resorption. He had seen a specimen exhibited recently at the Harlem Medical Association by Dr. McLean, in which a tumor had been honey combed, leaving only a core.

The President said he did not think that anyone had ever seen a carcinoma or adenoma in the abdomen disappear, except by operation. It was well known now that after the menopause solid tumors of the ovary and uterus did increase in size, but he thought that in the vast majority of cases, if these tumors could be examined and their structure determined, it would be found that they belonged to the fibroid order. He could not accept the theory that this sarcomatous change was a conservative effort of nature, because in his case the history showed that two months ago there had been a rapid increase, and from both macroscopical and microscopical study, it appeared that this sarcomatous change had taken place at the time that the growth of the tumor had become so rapid. The tumor referred to by Dr. Manley was a pure cystic sarcoma which had probably started as a solid sarcoma. It had overgrown itself, so to speak, and hence necrosis had taken place in the central portion. This was not the condition in his specimen.

The Society then went into executive session.

Stated Meeting, May 9, 1894.

George C. Freeborn, M.D., President, in The Chair.

A Lacerated Spleen.—Dr. Thomas H. Manley presented a lacerated spleen. It had been removed from a young sailor who had fallen from a mast, a distance of twenty feet, and striking against a rail, had sustained an injury in the region of the spleen. There was no disturbance of the sensorium, but there was profound and persistent shock, and he was in this condition when first seen by the speaker in consultation with his colleague, Dr. Charles B. White. There was no visible injury to the abdominal wall, and no distinct dulness on the injured side. There had been slight retching, but no vomiting except a little mucus. The symptoms pointed to internal hemorrhage, or to perforation of the intestine. The only pain complained of was localized below the left nipple. Assuming that there might have been a perforation of the intestine, laparotomy was resorted to. The peritoneal cavity was found to be filled with blood which was escaping freely from the spleen. A portion of the border of this organ had been torn nearly off. The lacerated fragment was quickly ligated and removed, but the man died on the operating-table.

The speaker said that he did not think it was possible in the living subject to produce a laceration of the spleen by a blow or fall, unless this violence was sufficient to produce disorganization of the overlying muscular tissues, which was not the case in this instance. His theory was that, as the man was only about twenty years of age, and the bones were not yet fully ossified, the spleen had been caught by the movable thorax and crowded up against the spine. He would like the opinions of the members on this point.

Dr. T. M. Prudden said he had seen several cases in which there had been laceration of the liver without injury to the abdominal wall.

The President said that within the past eighteen months several cases of extensive rupture of the liver had been presented to the Society, and in these there had been no evidence of injury to the abdominal walls.

Cranio-Tabes.—Dr. Thomas S. Southworth presented a specimen of cranio-tabes. The calvarium was very thin, and showed the condition of cranio tabes particularly well on the left parietal bone. The specimen had been taken from a child of about nine months, who had given every evidence of rachitis. It had been thought at one time that possibly hydrocephalus was developing, but the measurements of the head were found to be no greater than normal. At the autopsy no unusual quantity of fluid was found in the ventricles of the brain.

Uric-Acid Infarcts of the Kidney.—Dr. Southworth also presented a specimen from the same child, showing uric-acid infarcts of the kidney. He said it was not uncommon to find in the newly born, that the pyramids of the kidneys were filled with minute particles of uric acid or urates, but masses of the size shown in this specimen were certainly unusual. This condition raised the question of clinical interest—were these masses dissolved and absorbed, or were they passed along the ureters? If the latter occurred, it would afford an explanation of much of the colic and persistent crying of young infants.

Dr. O. C. Ludlow said that his clinical experience had abundantly confirmed the truth of this suggestion about the causation of much of the colic in the newly born. It was not uncommon to see such a sediment on the the diaper, or about the meatus urinarius, and under such circumstances it would be found that the administration of alkalies would quickly relieve the colic, and at the same time cause the disappearance of the sediment.

Sarcoma of the Antrum of Highmore.—Dr. R. C. Myles presented the pterygoid process and posterior part of the antrum of Highmore, and the pterygoid muscles, which had been removed from a case of sarcoma of the antrum of Highmore. The patient was a man thirty years of age, who had been referred to him by Dr. Wyeth for examination. A portion of tissue removed by the curette from the antrum was submitted to Dr. Prudden, who found it to be a large round-cell sarcoma. It was growing very rapidly. All of the sarcoma, as well as the superior maxilla, were removed by Dr. Wyeth two months ago. The patient is doing well, and so far there has been no recurrence. At first, owing to the loss of the pterygoids, the mouth was drawn to one side, but practice had overcome this difficulty. These cases of malignant disease of the antrum were not usually diagnosticated until the disease was far advanced. There were ordinarily very few symptoms, and hence at first these cases were apt to be obscure. He thought, if diagnosticated sufficiently early, all of them would recover. He would therefore strongly advocate an exploratory operation for diagnostic purposes.

Exostosis and Ecchondroma of the Vomer was also presented by Dr. Myles. It had been situated between the perpendicular plate of the ethmoid and the vomer, just beneath the sphenoid bone. He had found that in nearly every instance the cartilage had extended up to, or very nearly up to, the sphenoid bone. The specimen was concave on one side.

A Water-sampling Apparatus.—Dr. T. M. Cheesman exhibited the apparatus. He said it involved no new principle, but was an adaptation of a device described in "Fluegge's Micro-Organismen," and originated, he believed, with Pasteur. Its object was to collect a sample of water from a given level in a vacuum bulb by breaking off the end of the capillary tube when the bulb had reached the desired level in the water. Glass bulbs, 2.5 ctm. in diameter, and having a neck 2 ctm. in length, are drawn out into capillary tubes, and these are given a double bend. The gaseous contents of the bulbs are then driven out in the usual way by evaporating a few drops of water in them, and then sealing the ends. In such a bulb the surface of tap water could be easily collected by breaking off the end of the tube with the finger. The sample thus obtained should then be placed in a large, cotton-plugged sterilized tube, and carried in an ice pail to the laboratory. The object of the apparatus exhibited was, however, to facilitate obtaining samples at different depths or from inaccessible places. It had been suggested by Dr. Prudden, and had been elaborated by the combined talent of several others. Its utility had been fully demonstrated in actual practice.

The apparatus consists of a metal tube of small calibre, and about one metre in length, divided off into

equal parts. To the lower end of this tube are soldered two rings for supporting two vacuum bulbs. Beneath these two rings are two broken rings arranged to slide on the end of the tube. They are held in place by a rubber strap or band.

In collecting samples, the capillary ends of the bulbs are broken off when they have been immersed respectively at the levels from which it is desired to take samples of the water. The breaking off of these ends is accomplished through the instrumentality of small copper wires attached to their bent ends, and actuated by the finger of the operator. Breakage is facilitated, and fracture at the desired point is insured, by making a cut previously in the glass with a file or diamond at the proper point.

Formalin and Bacterial Growth.—Dr. Cheesman also exhibited specimens showing the effect of formalin in arresting the growth of bacteria, and its effect on gelatine already fluidified by bacterial products. Formalin, he said, was a forty per cent. solution of formaldehyd ($C H_2O$), a gaseous body produced by subjecting methyl alcohol to oxidation. It is soluble in water in all proportions, and is placed on the market in a forty per cent. solution. As it is very inflammable, care must be taken about employing it near a light or fire, and it is important that the preparation should have been recently prepared, as it loses its properties by keeping.

Dr. Cheesman then exhibited the following specimens:

The first one was a potato which had been cut in half without antiseptic precautions, and one-half smeared with the soil clinging to the outside of the potato, and the other half with a culture of B. prodigiosus. Both halves had been kept for fourteen days in an air-tight jar, charged with the vapor of formalin. No growth had developed.

The second specimen showed the effect of formalin vapor upon a culture of B. mycoides in gelatine, grown for three days at a temperature of an ordinary room before being subjected to the formalin vapor. The growth had been arrested and the fluidified gelatine on the surface had become solid. The medium still remained clear, but had undergone a slight change in color.

The third specimen was a "roll tube" of B. subtilis, one of the most actively fluidifying species. The growth had been arrested by the formalin vapor.

The fourth specimen was a water-plate upon which, after two days of growth, about 1 c.c. of formalin had been placed, and the cover sealed on with paraffine. The growth had been completely arrested.

The speaker said that formalin had the peculiarity of rendering solid gelatine which had once been fluidified by bacterial products. So far as he knew, ordinary gelatine as well as that which had been fluidified by bacteria, was thus rendered incapable of being liquefied by heat. It was claimed by those who had introduced formalin, that the microscopical appearances of the bacteria colonies were not affected by the formalin. If this were true, it would be useful for making microscopical "mounts" of colonies cut from gelatine plates. The cut section from the gelatine could be placed on a slide, surrounded by gelatine, covered with glass, and placed in an atmosphere of formalin. It could be varnished to prevent drying.

The President remarked that he had seen a published statement by one experimenter, to the effect that the heat from a Bunsen burner would char the gelatine which had been acted upon by formalin, but would not fluidify it.

Epithelioma of the Hand.—Dr. Henry Power presented microscopical sections of an epithelioma of the hand. According to the clinical history, the patient, a man seventy-five or eighty years of age, had had an epithelioma on the back of the hand for about eight years. He suddenly developed marked jaundice, emaciated rapidly, and died in eight weeks. At the autopsy the organs were found to be normal except the liver and gall-duct. The latter was distended and contained some gall-stones. There was a growth in the neighborhood of the common bile-duct, which completely occluded it. It seemed to be composed of adenoma, some fibroma, and in places closely resembled in structure the epithelioma of the hand. The latter showed very large epithelial "pearls," and also some peculiar cells which gave the appearance of having a thick capsule.

New Instruments.

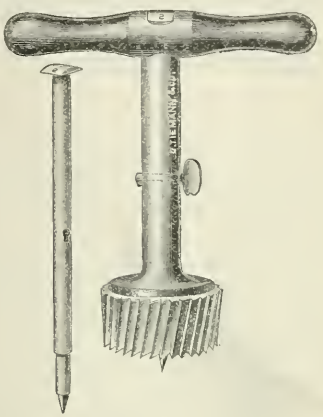
A NEW ASEPTIC TREPHINE.

By EMORY LANPHEAR, M.D., Ph.D.,

St. Louis, Mo.

Professor of Operative Surgery and Clinical Surgery in the St. Louis College of Physicians and Surgeons.

Surgeons who have had much experience in opening the skull by means other than the chisel, will bear out my assertion that the ordinary Galt trephine is not and cannot be made aseptic; furthermore, it is exceedingly liable to get out of order at a most inopportune moment. The Roberts trephine was made to overcome this difficulty; while it is a thoroughly aseptic instrument, it possesses the disadvantage of being liable to drop to pieces at the most unfortunate and critical point of the operation; otherwise it is perfectly satisfactory. Bearing in mind the faults of these two instruments, I have sought to remedy the deficiencies by the invention of the trephine here pictured.



This instrument consists of but three pieces; it can be taken apart in an instant; and is thoroughly aseptic. The sharp blade is attached to a large, strong metal handle through which passes the centre-pin, held in place by a little key which transfixes shaft and pin. Upon withdrawal of the key the centre pin can be removed without taking the saw from its groove, if so desired. The hole for the centre-pin is large, of smooth bore, and can be readily cleaned with a piece of gauze, and the whole instrument can be boiled without danger of rusting.

Acknowledgment of indebtedness to Messrs. Tiemann should be made for valuable suggestions in regard to modification of original plan.

Trismus Neonatorum.—Dr. I. Stefanesco, writing in *Spitalul*, No. 8, 1894, says that the greatest mortality among the new-born in the district of Ilfov, in Roumania, is from tetanus arising from infection through the umbilicus. In a careful study of a series of these cases he has found that the chief cause of this infection is the practice, very common among women in the country districts, of being delivered lying on a bed of straw in supposed imitation of the Virgin Mary.

A NEW UVULATOME.

By SAMUEL GOLDSTEIN, M.D.,

NEW YORK.

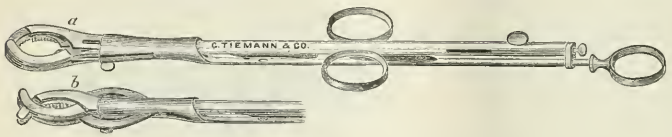
ASSISTANT SURGEON, NEW YORK THROAT AND NOSE HOSPITAL; ASSISTANT SURGEON, OUTDOOR DEPARTMENT, MOUNT SINAI HOSPITAL.

Amputation of the uvula, in vogue even as far back as the Hippocratic era, is to-day classed among minor operations upon the throat. The instruments used during primitive ages hardly find a place in the armamentarium of the surgeon of this progressive age. Then the unfortunate possessor of this organ, when hypertrophied or relaxed, suffered much torture in its abscission. Even to-day, with the many modified and complicated instruments, the patient is often compelled to undergo much shock through delay in the proper working mechanism of such appliances.

With the means at hand, however, the general practitioner, as well as the specialist, finds no hesitancy, when deemed necessary, in removing a portion of this organ.

After having tried many of these instruments with the usual amount of success, I was compelled to resort to the use of the forceps and curved scissors.

In the use of these simple instruments, both hands of the operator are engaged; the tongue must be depressed



either by the patient himself, or by the aid of an assistant.

The patient is left in full possession of his senses, and comprehends fairly well what is about to ensue.

That alone to the sensitive mortal creates very often a feeling akin to fear, and a wish that the operation were speedily performed.

It has been my experience, in the main, in amputating the uvula, to meet a class of patients whose throats, on account of the condition of this pendulous organ, were extremely sensitive, and to whom the touch of the tongue depressor, unless very carefully used, occasioned considerable gagging.

This would delay and prolong operative work.

In just such cases I have experienced much difficulty in having the patient properly depress his tongue, thus preventing expeditious and successful performance of this otherwise simple operation.

With these facts in view, believing that some simple contrivance could be planned whereby the surgeon himself could perform the entire operation, without intervention of either patient or assistant, I have made this uvulatome, hoping that it will supply for others, as it has for me, a long-felt want.

In drawing the plans, I have endeavored to keep in view the following points:

1. That the instrument be so constructed as to *fit* and *cut* uvulæ *of any diameter*, whether hypertrophied or relaxed.

2. That the knife be concealed, so as to give the patient no cause to fear operative procedure.

3. That the entire operation be performed by the surgeon himself.

4. That the instrument can be readily taken apart for cleaning.

This uvulatome consists of an upper and lower set of rings or claws, and between these a concealed knife.

Each set of claws (there being two segments to each set) is attached to a staff. A cannula incloses them at their narrowest parts. It is by the backward and forward movements of this cannula (at the lower end of which is a ring for the thumb) that the claws are drawn together, holding the uvula firmly, and relaxed, releasing the uvula.

Between the staffs of the claws is the staff of the knife (which is released by the cannula being pushed forward, lifting a catch) to which two rings are attached. The knife glides between the two claws and its action depends upon the backward and forward movements of the index and middle fingers in the rings attached to the staff.

Each set of claws is so arranged that the tongue of the one fits between the two lips of the other.

The upper set have their inner surfaces smooth, so as not to injure the stump of the uvula, while holding it firmly; the lower claws have their inner surfaces serrated, in order to better hold the amputated part, after the uvula has been cut.

The working mechanism is as follows:

The uvula is examined, and the exact amount to be amputated is determined. The surgeon depresses the tongue with the left hand (holding the uvulatome in the right), and with the thumb in the ring at the end of the cannula, and the index and middle fingers in the rings on either side of the staff of the knife, place the uvulatome in position, encircling the uvula.

The thumb ring is pushed forward (from the operator), thus pushing the cannula over the claws, and bringing them together grasping the uvula tightly; then with the index and middle fingers, pull backward (toward the operator), cutting through the uvula.

The operator should bear in mind, that it is very important to first grasp the uvula well with the claws, before bringing the knife into action.

To release the stump, the opposite action of the thumb opens the claws; and likewise, the opposite action on the staff of the knife pushes that backward.

The amputated portion of the uvula will be found caught in the serrated teeth of the lower set of claws, which for this purpose are made to fit closer together, so as to grasp the part of the uvula about to be cut, more tightly.[1]

I wish to express my thanks to Messrs. Geo. Tiemann & Co., for the excellent and thorough manner in which they have executed my plans.

166 East Ninety-third Street.

The Predilections of French Women Students.—Of the total number of women university students in Paris, 155 are on the list of the medical faculty, 164 on the list of the faculty of letters, 7 in the department of science, and 3 in that of law. Of the 155 medical students, however, only 16 are Frenchwomen, while of the 164 students under the faculty of letters, 141 are of French birth.

Gold Mines in Cemeteries.—A writer in *Le Temps*, of Paris, has been travelling in America, and, of course, relates his "impressions." What struck him particularly was not the Falls of Niagara, the inquisitiveness of reporters, or the consumption of pie, but the fillings in American teeth. He has consulted the statisticians and finds that the amount of gold annually pounded into our dental cavities reaches the respectable figure of 800 kilogrammes, representing a value of half a million dollars. All this precious metal is buried with the Yankees when they die, and consequently at the end of three short centuries the cemeteries of the United States will contain gold to the value of $150,000,000. He thinks this will prove too tempting to the practical mind of the future American, and foresees the day when companies will be organized to mine the cemeteries and recover the gold secreted in the jaws of deceased ancestors.

[1] Should troublesome hemorrhage follow the operation, the emergency can be met by reclamping the claws of the uvulatome over the stump, and keeping it in this position until all bleeding has ceased.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

HOLIDAY SIGNS—THE TEMPERANCE BREAKFAST—DR. LONG FOX'S ADDRESS—IS LUNACY INCREASING?—PROFESSOR JEBB ON THE UNIVERSITIES—A QUINQUENNIAL CENSUS—DEATH OF DR. C. R. ALDER WRIGHT—A STATUE TO SYDENHAM—THE NEW ELEMENT IN THE AIR—THE OPHTHALMOLOGICAL CONGRESS—THE MIDWIVES' QUESTION—POOR LAW SCANDALS—THE CHELSEA HOSPITAL—CHOLERA—SMALL POX—DR. WIGLESWORTH.

London, August 17, 1894.

The holidays have begun in earnest. The exodus from Bristol was rapid, and except a few who went to Oxford, most of our friends have left London. Still it is not quite accurate to say "London is left without doctors," as some people are fond of remarking; for there are plenty to do all the work that has to be done, and some of those who remain in town declare they have too much time on hand, and would be glad of more practice. After the Bristol week, with its discussions and unbounded hospitality, a little repose is a relief; and, then, a change of air will be most acceptable.

Among agencies at the Bristol meeting outside the Association the breakfast given by the National Temperance League was most notable. This is the twenty-fifth year in which the League has given a breakfast, and on this occasion Dr. Long Fox, the President of the Association, occupied the chair and delivered a most impressive address. He did not attempt to go over the old arguments nor to offer new ones respecting the temperance question, but contented himself with pointing out the immense influence of his professional brethren, and making an earnest appeal to them to use that influence aright. "We want more power and greater influence," said Dr. Fox, "and when we see whole families in the lowest state of degradation from the drunkenness of one parent or both, and now and then trace the change to prosperity on giving up the drink, it seems to me one of the strangest things on earth that anybody should shrink from being an apostle of temperance." When the cheers that greeted this sentiment had subsided the President added: "Speaking in the presence of some of the most thoughtful and excellent members of our body, may I say if we have light on this subject it behooves us to use it in a missionary spirit. We can do something in this way to remove the stones from the king's highway. The cry comes down to us, 'Watchman, what of the night?' It hath been long, O Lord! and very dark, but already over thine eternal hills the red light gloweth that heralds the approach of morning. Already out of the people of our beloved land some sixth part have shaken themselves free by thy grace from the hideous evil that tends to the destruction of the nation. We look for thy sun to rise ere long and flood this chosen country of thine with fuller and deeper light from thee. God grant that the coming generation may see a nobler and more effectual fight against this great evil, the most pregnant cause of poverty, disease, and crime. May the common-sense of England and the righteousness of England so permeate the daily life of the nation that, by and by, there will be no need of this society or of kindred societies, because the freedom of which we so justly boast will include freedom from all excess." Among the speakers who followed were Professor Murdoch Cameron, Drs. J. J. Ridge, W. G. Mackenzie, Roger Hughes, and Norman Kerr. All these made good points, but I may safely say not one produced so deep an impression as the testimony of Dr. Long Fox, who showed his earnestness by snatching time to attend this breakfast amid the numerous distractions to which he was subjected as President of the British Medical Association. This noteworthy breakfast was on Thursday morning. In the evening of the same day the dinner of the Association was celebrated as usual, when wine was served as freely as ever, and as much nonsense was talked as usual—so at least I gather; but I did not spend my evening at that dinner.

Is insanity on the increase, is a question that the newspapers have often taken up, sometimes giving expression to alarming forebodings. It has always seemed to me that the facts did not justify the sensational statements that have been freely circulated, and the "Report of the Lunacy Commissioners" does not substantiate them so far as I have been able to examine. The census statistics show that there is a considerable reserve of cases unknown to the commissioners, and this reserve has fallen from 17.7, in 1871, to 10.9 in 1891. In those twenty years the cases known to the commissioners increased from 82.3 per cent. to 89.1; but this only shows that a larger number had passed into asylums, and so became known to the commissioners. Statistics also show that new cases were fewer in the last decade than in the preceding one, and the increase so freely talked about is therefore partly due to the accumulation of cases, which has been brought about through the decreased mortality and increased longevity of the insane. There has been an increase in the ratio of insanity to the population, but it is all confined to the old, or rather to those above forty five years of age. It can hardly be supposed that this is due to new cases at advanced ages, and it seems clear that all the apparent increase has had no real existence. Improved treatment, greater willingness of the public to resort to asylums, decreased death-rate, increased longevity, accumulation of old cases, and other causes account for the figures, and we may reassure ourselves that the nation is not becoming insane.

Professor Jebb has published his very interesting address at the Cambridge University Local Lectures Association, in which he takes broad views of the duties of our old universities. The address is entitled "The Work of the Universities for the Nation," and is worthy of the professor's great reputation. Passing by his happy sketch of the earlier history of these seats of learning, he points out how they have enlarged their scope and have at length stepped out from their own gates to extend their influence in a wider sphere. No doubt many still have misgivings as to this movement; but so far it seems to have succeeded, and will probably be the means of drawing a larger number into nearer association with the universities. Mere technical instruction is not their proper work, but rather to bring students to see and apply general principles to all their work—even in the most technical employment. In no branch is the higher culture of greater importance than in the sciences which underlie medicine, and the influence of the universities on the profession is most important. Our relations with other learning have grown more intimate in spite of our devotion to science, and the Association has, I have no doubt, been mutually benefited.

London is to have a quinquennial census—to be begun in 1896. This is not undertaken for statistical ends in general, but in order to carry out the arrangements for the equalization of rates. This measure seems to be just, but the richer parishes will contain a considerable number of dissentients to this view. The County Council is to be saddled with the expense, which will amount to £6,000 or £7,000. No doubt it will tend to the accuracy of vital statistics and be useful for other purposes, but the manner in which it is brought about, as a sort of side issue, is characteristic of the ways of politicians.

The medical school of St. Mary's Hospital has sustained a serious loss in the decease of Dr. C. R. Alder Wright, F.R.S., the distinguished lecturer on chemistry. His many researches are familiar to all who have paid any attention to the progress of chemistry. His share in the discovery of apomorphine, and his work on the alkaloids of aconite, are the most important from a medical point of view, but they are only a small part of his scientific investigations. He lectured at St. Mary's for nearly a quarter of a century, and his many pupils will regret his

death. He took the Doctorship in Science at the London University soon after that degree was instituted, and has contributed to the repute in which it is held.

London, August 23, 1894.

At the Oxford meeting of the British Association for the Advancement of Science a pleasant event was the unveiling of the statue of Sydenham by the President of the Association and Chancellor of the University, Lord Salisbury. On behalf of All Souls' College, Sir Henry Arland begged the acceptance of the statue by the University, and the Chancellor in accepting it made graceful allusion to Sir H. Arland's work, and to the growth and renewal of the study of nature, of which the museum where they were assembled was the outcome. It is curious that Sydenham, who was a Fellow of All Souls', did not take his degree at Oxford, but at Cambridge, and it has been conjectured that this was due to his Roundhead proclivities or connections, but we really have hardly any reliable information about him until he had established his position as the leading physician of his day. It is sometimes said that he was never admitted as Fellow of the London College of Physicians on account of political feelings, but there is no proof of this. The college was very likely as much a clique as it is in our own day, and Sydenham, like some of our contemporaries, might object to show subserviency to the governing clique.

Of course, the sensation of the Oxford meeting was the announcement that a new elementary body had been isolated in the atmosphere. You will have heard of all this from other sources, so that I shall only say a word. This new element—if indeed it be one—is even more remarkable than nitrogen for its indifferent qualities. Perhaps it may be after all another form of nitrogen, but on this chemists have not had time to come to an agreement. But the discovery, or even the looking for an unrecognized element in the atmosphere, is full of suggestion for the future, to say nothing of the reproof it offers for neglecting to do so in the past.

The International Ophthalmic Congress, the eighth of the series, has been celebrated at Edinburgh under the presidency of Dr. Argyll Robertson, who referred in his address to the circumstance that the first department of medicine to institute such a congress was ophthalmology. That was thirty-seven years ago. The deaths of Donders and Becker since the last Congress (which was held at Heidelberg in 1888) were touched upon with due reverence, and the illness of Helmholtz was spoken of with sympathy. There were some one hundred and fifty members present at this Congress, and I hear that some valuable papers were brought forward.

Dr. Rentoul is continuing his campaign on the midwives' question. He has just issued a pamphlet entitled, "The Proposed Formation of an Inferior Order of Midwifery Practitioners: A Reply to Dr. William Carter's pamphlet." This reply is one that will give much satisfaction to a large number of medical men. The few who are so anxious to recognize midwives and register them are very fond of putting forward the plea of suffering parturient women, as if their opponents were not equally humane. The truth is, there are too many doctors in most localities, and it is no wonder they do not relish the proposal to register midwives. Consulting accoucheurs have little experience of the requirements of the people.

Scandals connected with the Poor Law seem to multiply, or perhaps it is that they are being made more public. Some of these I have already reported and others are cropping up. The *British Medical Journal* has been busy in the matter lately, the editor following up the investigations set on foot so many years ago by the *Lancet*, and claiming credit for work undertaken and paid for by the proprietors of the *Lancet*. The infirmaries are some of them well managed, but it must be admitted that the nursing is in a great many inferior—and in some it may almost be said there is no nursing at all.

The Chelsea Hospital for Women has taken the next step in its reorganization by electing its honorary staff. This has been reduced in number and a couple of outsiders have been introduced. The others have been chosen from the former staff, which, as you will remember, had resigned. We shall hear more of the matter yet. Already some statements have appeared on behalf of the staff which go far in support of the view I have expressed.

The cases of cholera in a vessel arriving in the Thames have been reported as real Asiatic cholera, the comma bacilli having been found. Another suspicious death occurred in Battersea and was submitted to Dr. Klein, but in this case he was unable to confirm the suspicion from bacteriological examination. Every precaution is being taken to guard the port of London, and cases of diarrhœa on board vessels arriving are ordered to be notified.

Small-pox continues to hold its ground, though with considerable variations from week to week. In the last return there were only 22 cases. There were 10 deaths registered, of which 7 were in the parish of Marylebone, where Dr. Blyth has been most active in preventing the spread of the disease. He is well supported by his sanitary authorities, who seem conscious of their responsibilities, and we have little doubt that all necessary measures will be taken. The outbreak has given a much needed impetus to vaccination, in spite of the follies of the antis. A strictly localized outbreak produces infinitely more alarm than a more wide-spread epidemic, and thus inoculates a larger number of people with fear, and there is a rush to the vaccination stations.

Dr. Wiglesworth's wound was more serious than at first reported. The carotid artery was wounded and had to be tied. He walked through a corridor for some distance to his house, applying pressure himself until assistance was obtained. It is satisfactory to learn that he is going on well.

MEDICAL COLLEGES AND THE MEDICAL PROFESSION.

To the Editor of the Medical Record.

Sir: Perhaps many interested readers with far abler pens than mine will feel in perfect accord with the quoted remarks of Dr. Cochran, as found in the Medical Record of July 28th, editorially referring to the marked increase in the number of medical colleges in the United States.

Statistics yearly show a great army enlisted in the study of medicine, and comparatively large classes of graduate students. It is amazing to think of the number of these so-called medical colleges. It is also a matter of wonder and more than apparent concern to regular practitioners where the army of annual recruits are to go. Here in Ohio, with a dozen times as many colleges as are needed, and with a large migration of young doctors from other States, we now startle the population of our great State with the fact that every three hundred and fifty people have their physician. This, of course, is only approximate, for there never can be an even distribution, and, if there could, every physician well knows that it requires an allotment of eight hundred to one thousand persons to even earn a livelihood in the practice of medicine.

Dr. Cochran suggests the only real remedy. Let every State follow the example of Alabama and limit the number of colleges chartered. Let the requirements in the few allowed be in accord with the professional spirit of the age.

There is no excuse for even this great State having more than two medical colleges. The writer can name medical colleges in this State where clinical work in any department is entirely unknown. Yet the degree that ought to signify so much is belittled. Perhaps Pennsylvania has fewer medical schools compared with her great importance and population than many of the other States.

But who can honestly claim that old Pennsylvania really needs more than two or three high-grade medical schools? So we might go over the list of States with the same result.

It seems far more just that each State should have certain colleges of high standard which would put every State and the whole medical fraternity on equal footing, than that young men graduating recently should be subjected to a senseless so-called examination by one of the several State boards for the ostensible purpose of experimentation. So far as its protective features go for the people at large, it is simply a sham. The author can name three examiners on one of the most prominent State boards who never attended but two five-month terms of lectures in their lives. Every physician in practice knows how soon he forgets many of the even important details of a subject, and how soon he gets notions peculiar perhaps only to himself. Is it just to expect such men to be able to give a student graduating from a well conducted school an impartial and strictly righteous test? We believe it to be neither fair for examiner nor for the student. The whole idea of State board examination is a sham, and will surely be exploded ere many years, as it most heartily deserves to be.

One good general law providing for the regulation of the number of medical colleges, the establishment of a certain adequate standard, the abolition of quackery, and one fair but very thorough collegiate test by a combined board of faculty of college and corresponding State authorities would do more good, give better satisfaction to the profession, afford at least more than a show of real protection to the people, and be vastly fairer to those young men and women who filled the requirements. In addition, no good reason can be given why one such test should not be accepted as satisfactory, wherever the person interested might wish to locate and practise.

W. C. McGEE, M.D.

Little Sandusky, O.

CLIMATE AS AFFECTING THE PRINCIPLES OF APPLIED THERAPEUTICS.

To the Editor of the Medical Record.

SIR: Too much attention is given by the teacher of therapeutics, in the average medical school, to exact dosage, minimum and maximum doses, and the specific action of drugs, and not enough to the circumstances which may attend any case to which a physician may be called.

The beginning practitioner is all at sea. He has been taught that he can accomplish certain or positive results by the use of such therapeutic agents as have come into use in the progress of medicine. Accordingly, he gives a dose and then watches for it to act characteristically and immediately, as he would watch the dial of a steam gauge when a fire is built in the furnace of a steam boiler. Not getting the expected result, he mumbles "idiosyncrasy" to himself and tries another drug. He hops from one to another and is tortured by anxiety, fear of failure, dread of public condemnation, etc. If he is so fortunate as to meet with cases which would not require any prompt and decided measures until he can begin to shape his senses and learn the practical use of drugs, he will gradually learn that which ought by some means to have been taught him in college, but which seldom or never is taught.

How few authors or teachers of medicine ever consider the matter of how climate may influence the action of drugs, or of what particular drugs may be modified in their action by differences in climate. The text or teacher says that a certain drug produces such an effect if given in such a dose, at such a time of the day. Its action is modified by the diet of the patient, perhaps by the disease from which he is suffering, and by some other drugs which should, or should not, as the case may be, be administered along with the drug under consideration. Then follows a list of the uses of the drug, but seldom a list of the abuses of the same, which would be of vastly more importance to the student and patients.

Drugs, which in New England, the Middle, and upper Mississippi Valley States produce a characteristic action, may utterly fail to characterize themselves in the South or on the Pacific coast. Cathartics which, in the States east of the Rocky Mountains and above Mason and Dixon's line, produce their effect when given in such doses as are prescribed by the faculty in those regions, produce small or no effect on the Pacific coast. Narcotics are less effectual here and more depressing in their subsequent effects. The much lauded and most excellent system of milk diet is limited to a minority of the class of cases to which it would be applicable in other portions of our country. Many small children will not take milk when well, and cannot take it, no matter what the process of preparing it may be, when they are sick. While the climate here is such that butter seldom gets rancid or unpalatably soft, even when subjected to the ordinary temperature of the air, yet milk from healthy cows, and handled and kept in the most cleanly manner, will ferment and curdle in less than twelve hours, unless scalded or boiled. People who were fond of milk as an article of diet on the other side of the Rockies come to dislike it here. Very few native-born Californians ever touch milk after once becoming accustomed to a general diet. Very few can take milk when sick. It is a most exasperating affair at times to find a suitable diet for the sick. As a rule, meat broths, free from fat and reasonably condensed, administered in quantity of from three to five ounces to an adult every two or three hours, is our mainstay in the class of cases which we are told to keep on milk in the East. The milk will curdle in tough masses and be vomited, or set up a diarrhœa due to fermentation and sadly aggravate the case.

Lobar pneumonia and capillary bronchitis are more frequent than other forms of acute pulmonary disease. Pneumonia rarely gives as high a temperature here, or as characteristic symptoms as in countries having rigorous winters, and rarely terminates by crisis, but by lysis.

It is harder to decide upon the proper time to administer stimulants, and a greater quantity will be tolerated than in the eastern portion of the United States.

All diseases are apt to follow a slower course than in the East, and convalescence is much slower and less sure.

In regard to the much lauded climates of the Southwest, to which many patients are shipped who are suffering from pulmonary troubles, I feel sure that few physicians would continue to send patients there if they could see the country. The mental, moral, and physical conditions are all depressing to any new-comer, unless he be philosophical enough to make the best of the poverty of nature. The alkali dust, barren plains, hot days, and cold nights, with ragged Indians, dirty, ragged, nomadic, mixed inhabitants, poor food, poor accommodations, absence from home and friends, strange climate, and fatigue of a long journey, make a combination of most unsuitable circumstances for an invalid. The tourist on a pleasure excursion sees only the best, hears the best, tastes the best, and believes the best. More can be done for pulmonary cases, especially when the disease is well advanced, by keeping them in a pleasant, well-ventilated room, kept at a constant temperature throughout the twenty-four hours, and the best hygienic measures carried out, together with such remedies as the necessity of the case may require from time to time, than in any or all of the health resorts of the earth. This may not be the popular view of the case, but it is the practical side of it.

E. A. SMITH, M.D.

Santa Clara, Cal., August 13, 1894.

The Value of a Doctor's Health.—Dr. W. S. Lumpkin, of Atlanta, Ga., sued that city for $10,000 damages, alleging that the injurious fumes from an open sewer had ruined his health. The jury found in his favor to the amount of $400.

Medical Items.

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 1, 1894.

	Cases.	Deaths.
Tuberculosis	62	108
Typhoid fever	33	14
Scarlet fever	17	3
Cerebro-spinal meningitis	0	4
Measles	14	2
Diphtheria	112	33
Small-pox	13	2

Quackery is rampant in Paris, though, perhaps, they have not as many faith healers and itinerant impostors as we have in America; yet there is a larger proportion of regularly educated physicians who, weary of the restraints imposed by the regular profession, boldly announce their wares through every sort of advertising medium. And why should they not, when the venerable scientist, Brown-Séquard, is the greatest sinner of them all? Everywhere, on lamp-posts, in urinals, in railway stations, and in the most out-of the-way places along railroad lines, in every direction, one will see large banner posters advertising the "*Suc de Brown Séquard; très précieux*," etc., for nervousness, diminished sexual power in men or women, old or young.—Paris Correspondent of *Medical and Surgical Reporter*.

Dr. L. C. Lane is the leader of the Cooper school faction of the profession in San Francisco. He has recently donated a handsome hospital to Cooper Medical College, which college already occupies a handsome building for college purposes, donated by Dr. Lane. A marble tablet in the auditorium of the college informs the reader that the building was erected out of funds earned by Dr. Lane in his profession. As the site and buildings must have cost on toward a half-million of dollars, Dr. Lane has likely made more money out of his professional work than any other medical man who has ever lived.—*Medical Sentinel*.

Portland's Hospitals.—While we have much to felicitate ourselves upon regarding the character of the work of our Portland hospitals, says the *Medical Sentinel*, yet a visit to a city of any considerable size, or to a city the size of Portland, will convince anyone that in numbers, at least, Portland falls far behind in this matter. Take San Francisco, for instance. A half-dozen hospitals there are equal, for San Francisco, to what the hospitals here are for Portland. Their larger capacity will compensate for the difference in the size of the two cities. But beyond these there are about twenty five other hospitals in San Francisco. It is quite likely that a number have to struggle vigorously to subsist, but the fact that they do subsist year after year, is evidence that there is a place for them. A city has to reach a certain size before hospitals devoted to special lines, or managed for special nationalities or civic divisions of mankind will flourish. Portland is fast approaching such period. It may have reached it.

Sterilization of Catgut by Heat —Professor M. Schüller, of Berlin, says (*Aerztl. Praktiker*, No 30, 1894) that the question of sterilization of catgut is of importance not only to the surgeon and gynecologist, but to every general practitioner. The physician should not content himself with the material offered by druggists and dealers in surgical supplies, but he should be able to sterilize it himself. The methods thus far employed to sterilize catgut are tedious, and for the most part unreliable. The author first tried dry heat, but gave this up as being too tedious. He then experimented with hot fluid, of different kinds. None proved as satisfactory as oleum lavandulæ, an ethereal oil free from oxygen and of very agreeable odor. Catgut loosely rolled up in rings is placed in a wide-mouthed bottle containing lavender oil. The bottle is to be filled up to the stopper, which latter is to touch the surface of the oil. Care is to be taken that all the catgut in the bottle is well covered, because parts which have been above the surface of the oil during the process of sterilization will become brittle. The bottle, hermetically closed, is placed in the steam sterilizer and there subjected for a half-hour to a temperature of from 106 to 110° C. The catgut having been sterilized in this manner is supple and does not tear under ordinary force. The catgut is removed from the bottle by means of sterilized forceps for immediate use, or to be placed in sterilized water or in carbolic acid solution until needed for use. The lavender oil possesses the special advantage over many other fluids, especially oils, in that the same oil can be used repeatedly.

Prize Essay of the Colorado State Medical Society.—The conditions for the $100 Prize Essay voted by the Colorado State Medical Society (June 21, 1894) on the following subject: "The Diagnoses of Tuberculosis by Microscopic Examination of the Blood." Preference to be given to new evidence and the detection of the pretubercular stage. All stages, however, to be included and microscopically differentiated. Paper to be condensed to read in thirty minutes time; to be typewritten and the authorship kept secret till the award of the examining committee is made known. Prize open to anyone; essay to be written in the English language in comprehensive style and as free from purely technical expressions as possible; accuracy of definition and clearness of diction considered. The committee to reserve the award for an essay they deem sufficiently meritorious, *i.e.*, the rules to be observed enabling a diagnosis to be made from the blood alone without the patient being seen. A prize committee of three was appointed, Drs. Charles Denison, H. A. Lemen, both of Denver, and Dr. S. E. Solly, of Colorado Springs. (Dr. L. A. Fisk, of Denver, alternate), and all essays to be handed in under seal by April 1, 1895.

The following test is suggested as not unreasonable: Seven persons being in one room, representing, respectively, a person in health, a case of anæmia, one of leucocythemia, one pretubercular, and three representing the three stages of consumption *i.e.*, 1st, infiltration, 2d, softening, and 3d, excavation (advanced and extensive). In another room the microscopic examination of the blood of several of those, to determine from whom the specimens were taken. It is expected that the ordinary use of the $\frac{1}{6}$, $\frac{1}{10}$, $\frac{1}{12}$, or $\frac{1}{16}$ immersion lenses will answer. If not and there is any doubt, full explanations as to instruments or lenses used should be furnished.

The Association of American Medical Colleges.—Resolutions adopted at a meeting held in San Francisco, Cal., June 7, 1894.

Resolved, That colleges, members of this Association, shall require of all matriculates an examination as follows: 1. An English composition in the handwriting of the applicant of not less than two hundred words; said composition to include construction, punctuation, and spelling. 2. Arithmetic, fundamental rules, common and decimal fractions, and ratio and proportion. 3. Algebra—through quadratics. 4. Physics—elementary —gage. 5. Latin—An amount equal to one year's study, as indicated in Harkness Latin reader. (The above resolution does not apply to students exempt from the entrance examination, as per Sec. 2, Art. III.)

Resolved, That the following classes of students be recognized as entitled to apply for advanced standing in colleges members of this body: *a*. Such graduates of recognized colleges and universities as have completed the prescribed courses in chemistry and biology therein. *b*. Graduates and matriculates of colleges of homœopathy. *c*. Graduates and matriculates of colleges of eclectic medicine. *d*. Graduates and matriculates of colleges of

dentistry requiring two or more courses of lectures before conferring the degree of D.D.S. *e.* Graduates and matriculates of colleges of pharmacy. *f.* Graduates and matriculates of colleges of veterinary medicine. It is provided, however, that the above class of students be required to comply with the provisions of the entrance examination, and to prove their fitness to advanced standing by an individual examination upon each branch below the class he or she may desire to enter.

Resolved, That students graduating in 1899 or subsequent classes, be required to pursue the study of medicine four years, and to have attended four annual courses of lectures of not less than six months' duration each.

The Medical Profession in Texas is not a Unit, if we may be allowed to form a conclusion from a perusal of the pages of the *Texas Health Journal*. In the issue for July Dr. Cunningham has an article with the vigorous title: "The Amazing Infatuation of the Texas State Medical Association in Pompously Parading its Appalling Ignorance of the First Principles of Sanitary Legislation; and its Unbounded Cheek, and Unmitigated Gall in Presuming to Instruct Congress in the Proper Performformance of its Duties—Succinctly Set Forth."

The Physicians of Louisville are obliged to pay a license fee of $10 a year to the city.

Penetrating Wound of the Abdomen.—Dr. Dumitru Popescu reports in *Spitalul*, No. 12, 1894, the case of a peasant sixty-five years old who fell from a hay-rick, impaling himself upon a pitch-fork, one prong of which passed through the abdomen. He remained suspended for a time, until the weight of his body broke the prong and he fell to the ground. After himself pulling out the penetrating body he went home, and five days later applied for relief at the hospital. The abdominal wound was suppurating and there were symptoms of intestinal strangulation. Laparotomy being performed, there were found to be some adhesions and a hernia of the epiploon through the rectus muscle. The strangulation was relieved, and the inflamed epiploon severed, and the peritoneal cavity thoroughly irrigated with sterilized water. The man made a good recovery. The fork had entered in the left hypochondrium, and passing through the abdomen, had again penetrated the peritoneum and torn the rectus muscle, but had been then arrested by the elasticity of the skin.

The Michigan "Jag Cure Act."—The Legislature of Michigan recently enacted a curious statute known as the "Jag Cure Act." It allows a justice, upon the conviction of a disorderly person, instead of requiring a recognizance for good behavior, to accept recognizance conditioned that the defendant will take the cure for the liquor habit in conformity with the rules and regulations of some corporation administering the cure. The supreme court of Michigan has held the act unconstitutional, on the ground that it remits the nature and extent of the punishment to the determination of the fluctuating rules of a private corporation, and transfers, in a measure, the pardoning power of the governor to that body.—*Scientific American.*

Treatment of Gonorrhœa at the Necker Hospital.—At the Necker is the most complete arrangement for the study of gonorrhœa to be found in Europe. The clinic is under the charge of Professor Guyon, while the outpatients' department is conducted by Dr. Ganet.

Each case is thoroughly examined physically and the discharges microscopically before treatment is given, careful histories taken, and all changes in treatment recorded. As the daily clinic is large, the statistics from such a place should be exceeding valuable and reliable.

The irrigators proposed by Professor Guyon are in constant use, both in acute and chronic gonorrhœa and in cystitis. The liquid is placed one and one-half yard (or metre) above the bed or table upon which the patient lies, and the force thus obtained is sufficient to convey the liquid into the bladder, a small glass tip at the end of the rubber tube being held firmly in the meatus. In this manner he uses the potassium permanganate treatment. From one to two litres of a watery solution of potassium permanganate, in varying strengths, from 1 to 4,000 to 1 to 1,000, depending upon the stage of the disease, are passed into the bladder once or twice daily, the patient raising himself to a sitting posture and emptying his bladder from time to time. In this way the bladder may be thoroughly irrigated without the passage of a catheter, which, in cases of stricture, will often be of considerable advantage. In the same way solutions of silver nitrate (1 to 1,000), and of sublimate (1 to 5,000), are used in cystitis. Professor Guyon also uses stronger solutions of silver nitrate (one per cent. to five per cent.) and of cupric sulphate (two per cent. to seven per cent.) in obstinate cases of gonorrhœa.—*Paris Correspondent Therapeutic Gazette.*

Cauterizing Ovaries instead of Removal of them.—Dr. Pozzi, at Hôpital Broca, has now practised cauterization of painful ovaries for over two years, and considers the plan very successful. In one case, in which he

[illegible] then sews the end with silk. If there are some small cysts, he opens them by touching with the Paquelin point. The ovary being returned to the abdomen, he examines and treats the other in a similar manner. Often as many as six small cysts are opened in this way in each ovary.—*Paris Correspondent Therapeutic Gazette.*

Old Age and the Death-rate.—Only 906 persons in a million die from senility, while 1,200 succumb to gout, 18,400 to measles, 27,000 to apoplexy, 7,000 to erysipelas, 7,500 to consumption, 48,000 to scarlet fever, 25,000 to whooping-cough, 30,000 to typhoid and typhus, and 7,000 to rheumatism. The averages vary according to locality, but these are deemed pretty accurate as regards the population of the globe as a whole.—*Medical Age.*

Lady Mary Wortley Montagu on Inoculation.—In an article in the *Popular Science Monthly* for July, 1894, Mrs. Plunkett quotes the following account of small-pox inoculation from Lady Mary Montagu's letters: "Apropos of distempers, I am going to tell you of a thing that I am sure will make you wish yourself here. The small-pox, so general and so fatal among us, is entirely harmless here by the invention of *ingrafting*, which is the term they give it here. There is a set of old women who make it their business to perform the operation in the month of September, when the great heat is abated. People send to one another to know if any of their family has a mind to have the small pox. They make parties for the purpose, and when they are met—commonly fifteen or sixteen together—the old woman comes with a nutshell full of the matter of the *best sort of small-pox*, and asks what vein you will please to have opened. She immediately rips open the one that you offer to her with a large needle, which gives you no more pain than a common scratch, and puts into the vein as much venom as can lie upon the head of her needle, and after binds up the little wound with a hollow bit of shell, and in this manner opens four or five veins. The Grecians have commonly the superstition of opening one in the middle of the forehead and in each arm and on the breast, to make the sign of the cross; but this has a very ill effect, all the wounds leaving little scars, and is not done by those that are not superstitious, who choose to have them in the legs or in that part of the arm that is concealed. The children or young patients play together all the rest of the day, and are in perfect health till the eighth; then the fever begins to seize them, and they keep their beds two days, very

seldom three. *They have very rarely above twenty or thirty in their faces, which never mark;* and in eight days' time are as well as before their illness. Where they are wounded there remain running sores during their distemper, which I doubt not is a great relief of it. Every year thousands undergo this operation, and the French ambassador says that they take the small-pox here by way of diversion, as they take the waters in other countries."

Restriction on the Sale of Patent Medicines.—A bill has been introduced in the Iowa Legislature providing that every patent medicine offered for sale in that State shall have a printed statement on the wrapper giving the ingredients of the preparation. The penalty for disobedience to this law is a fine, not exceeding $100, or imprisonment for six months in the penitentiary.

Strophanthus is recommended by Dr. Skworzow in the treatment of inebriety. In the few cases in which he has tried it, it was given in seven-drop doses of the tincture. It gave rise to vomiting and profuse diaphoresis and quickly excited a distaste for alcohol which was said to persist after the withdrawal of the drug.

Books as Carriers of Infection.—Dr. McNicoll, an English health officer, states in a recent report that a book was kept under the pillow of a small-pox patient until his death. It was then taken in charge by his son, who lived in another part of the town, and after being kept without disinfection for four weeks in his house, was offered for sale to an artisan, who kept it overnight. While there the artisan's wife perused the book, with the result that, fourteen days later, she developed the rash of small-pox.

BOOKS RECEIVED.

MANUAL OF PRACTICAL ANATOMY: UPPER LIMB, LOWER LIMB, ABDOMEN. By D. J. Cunningham. Vol. I. 669 pages, 8vo, illustrated. Published by Young J. Pentland, Edinburgh & London. Imported by J. B. Lippincott Company, Pa. Price, $7.00.

MANUAL OF PRACTICAL ANATOMY: THORAX, HEAD, AND NECK. By D. J. Cunningham, M.D. Vol. II. 8vo, 647 pages, illustrated. Published by Young J. Pentland, Edinburgh and London. Imported by J. B. Lippincott Company, Philadelphia, Pa.

CLINICAL MEDICINE: A MANUAL FOR THE USE OF STUDENTS AND JUNIOR PRACTITIONERS. By Dr. Judson S. Bury, London. 8vo, 468 pages, illustrated. Published by J. B. Lippincott Company, Philadelphia, Pa. Price, $6.50.

DISEASES OF THE NOSE AND THROAT. By F. De Havilland Hall, M.D. 8vo, 524 pages, illustrated. Published by P. Blakiston, Son & Co., Philadelphia, Pa. Price, $3.00.

HUMAN PHYSIOLOGY. By John Thornton, M.A. 8vo, 436 pages, illustrated Published by Longmans, Greene & Co., New York. Price, $1.50.

TRANSACTIONS OF THE FIFTEENTH ANNUAL MEETING OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, HELD IN THE CITY OF NEW YORK, MAY 22, 23, AND 24, 1893. 8vo, 165 pages, illustrated. Published by D. Appleton & Co., New York.

THE DISEASES OF THE WILL. By Th. Ribot. 8vo, 134 pages. Published by the Open Court Publishing Co., Chicago, Ill. Price, 75c.

SMALL HOSPITALS. ESTABLISHMENT AND MAINTENANCE. By Dr. A. Worcester. AND SUGGESTIONS FOR HOSPITAL ARCHITECTURE, WITH PLANS FOR A SMALL HOSPITAL. By William Atkinson, Architect, 8vo, 114 pages, illustrated. Published by John Wiley & Sons, New York. Price, $1.25.

AN ILLUSTRATED DICTIONARY OF MEDICINE, BIOLOGY, AND ALLIED SCIENCES, INCLUDING PRONUNCIATION, ACCENTUATION, DERIVATION, AND DEFINITION OF THE TERMS USED IN MEDICINE, SURGERY, ANATOMY, ETC. By George M. Gould, M.D. Royal octavo, 1,633 pages, illustrated. Publishers, P. Blakiston, Son & Co., Philadelphia, Pa. Price, Full Sheep, net, $10.00; Half Morocco, net, $10.00; Half Russia, with Thumb Index, net, $12.00.

MEDICAL CHEMISTRY. By Elias H. Bartley, M.D. Third Edition. 8vo, 684 pages, illustrated. Published by P. Blakiston, Son & Co. Price, $3.00.

TEXT BOOK OF ABDOMINAL SURGERY. A CLINICAL MANUAL FOR PRACTITIONERS AND STUDENTS. By Skene Keith, F.R.C.S. Edin., assisted by George E. Keith, M.B., C.M. 8vo, 508 pages, illustrated. Published by J. B. Lippincott Company, Philadelphia, Pa.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY. Vol. XV. Royal octavo, 842 pages. Washington, D.C.

RETROSPECT OF SURGERY. By Francis J. Shepherd, M.D. 8vo, 259 pages. E. M. Renouf, Montreal, Can.

ESSENTIALS OF ANATOMY. By Charles B. Nancrede, M.D. 8vo, 388 pages. Illustrated. W. B. Saunders, Philadelphia, Pa. Price, $1.00.

ESSENTIALS OF NERVOUS DISEASES AND INSANITY. By John C. Shaw. 8vo, 194 pages. Illustrated. W. B. Saunders.

PRACTICAL LECTURES IN DERMATOLOGY. By Condict W. Cutler, M.D. 8vo, 233 pages. G. P. Putnam's Sons, New York. Price, $2.00.

URIC ACID IN CAUSATION OF DISEASE. By Alexander Haig. Illustrated. 8vo, 400 pages. Second edition. J. & A. Churchill. Price, 10s. 6d.

THE CARE AND FEEDING OF CHILDREN. By L. Emmett Holt, M.D. 8vo, 66 pages. D. Appleton & Co. Price, 50 cents.

A MANUAL OF INSTRUCTIONS IN THE PRINCIPLES OF PROMPT AID TO THE INJURED, INCLUDING A CHAPTER ON HYGIENE AND THE DRILL REGULATIONS FOR THE HOSPITAL CORPS, U. S. A. By Alvah H. Doty, M.D. 8vo, 304 pages. Illustrated. Second Edition. D. Appleton & Co.

A CLINICAL MANUAL. By Dr. Andrew MacFarlane. 8vo, 139 pages. Illustrated. G. P. Putnam's Sons, New York City. Price, $1.25.

REPORT TO THE NEW YORK CITY HEALTH DEPARTMENT ON THE USE OF BACTERIOLOGICAL EXAMINATIONS FOR THE DIAGNOSIS OF DIPHTHERIA.

By HERMANN M. BIGGS, M.D.,

NEW YORK.

PATHOLOGIST AND DIRECTOR OF THE BACTERIOLCGICAL LABORATORY.

EARLY in January, 1893, a communication was addressed to the Health Board of New York City recommending the systematic employment by the Health Department of bacteriological examinations for the diagnosis of diphtheria. This recommendation was made in view of the following considerations there detailed:

"1. The practical differentiation of diphtheria from other diseases affecting the upper air-passages is of great sanitary importance.

"2. It is admitted by all clinicians of experience in this disease that it is often impossible, either from the clinical history or the anatomical lesions, or both, to make an accurate diagnosis of diphtheria. There are no constant differences which separate the simple non-contagious forms of inflammation from the diphtheritic and communicable types, and it is only in a rather small proportion of cases that an early and reliable diagnosis can be arrived at from any data obtainable. The records of the Health Department of New York City have shown this in a very striking way. In the cases of suspected diphtheria under treatment at the Willard Parker Hospital, in which the diagnoses were made by the Department inspectors and confirmed by the Department diagnosticians before the removal of the patients to the hospital, subsequent bacteriological examinations showed that from thirty to fifty per cent. of these cases were not diphtheria, but were cases of pseudo-diphtheria.

"3. All recent bacteriological investigations made to show the value of such examinations for the diagnosis of diphtheria are in accord in stating positively that reliable conclusions may be reached by this method in from twelve to twenty-four hours. These investigations include those made by Baginsky in Berlin, Martin in Paris, and Koplik and Park in New York. The results arrived at in these investigations have been confirmed by the subsequent histories of the cases examined. In those cases in which bacteriological examinations have shown the absence of the Klebs-Loeffler bacillus, the mortality has varied from one to five per cent., and the cause of death has usually been broncho pneumonia, and not the local disease; while in those cases in which bacteriological examinations have shown the presence of the Klebs-Loeffler bacillus, the mortality has varied from twenty to nearly fifty per cent. Further, it has been demonstrated that in the cases in which the Klebs-Loeffler bacillus is not found there is little danger of the transmission of the disease to others; while from the cases of true diphtheria (as shown by bacteriological examinations), even when the disease is of the mildest type, frequent and numerous instances of infection have been recorded.

"4. The employment of bacteriological examinations for the diagnosis of diphtheria would have an important influence on the work required of officials of the Department and the cost of this work. Bacteriological investigations in diphtheria have shown that accurate conclusions can be arrived at as to the nature of the disease in most cases within fourteen hours. Investigations made by Dr. Park, at the Willard Parker Hospital, show the Department has in the past provided for the maintenance and treatment of a large number of patients having pseudo diphtheria. This has been at a large unnecessary annual cost, and the facilities of this Department for the treatment of cases of true diphtheria have been thereby limited. In addition to this, under the regulations of the Department at present, a large number of cases of pseudo-diphtheria must be repeatedly visited by inspectors, and the rooms, clothing, etc., after convalescence, thoroughly disinfected. This is at a further large cost to the Department, and the expenditure of much valuable time. If the Department was prepared to avail itself at once in all cases of means for the bacteriological diagnosis of diphtheria—as this can be arrived at in so short a time—any definite action could, as a rule, be held in abeyance until a conclusion as to the nature of the disease had been reached. In those cases in which the results showed the disease was pseudo diphtheria, the Department would be at once relieved from further action.

"During the year 1891, 4,874 cases of diphtheria were reported to this Board, and so far as can be judged from the data at hand, at least one-third, and perhaps more, of these were not diphtheria.

"5. The resort to bacteriological examinations for the differentiation of true diphtheria from pseudo diphtheria would constitute an important step in advance.

"The Health Department of New York City determined during the cholera outbreak in 1893 to depend solely on bacteriological examination for the diagnosis of Asiatic cholera. No State or Municipal Sanitary Board has as yet officially adopted bacteriological examinations for the diagnosis of diphtheria, but in this city these would be of far greater value in the diagnosis of diphtheria than in the diagnosis of cholera, because of the greater prevalence and constant presence of diphtheria here. The formal recognition of this method by the Board would be received by the profession as an important indication of the determination of the Board to keep the work of the Department thoroughly abreast of the most recent discoveries of scientific medicine.

"6. In addition to the work on the diagnosis of diphtheria, there would naturally arise from such examinations investigations as to the best methods to prevent the extension of this disease."

In the report just quoted, the appointment of Dr. William H. Park as bacteriological diagnostician and inspector of diphtheria, was recommended. Dr. Park's name was suggested because of the special investigations that had been carried on by him during the previous year in the hospitals under the control of the Health Department, and because of his special training and fitness for this position.

After some unavoidable delay, early in May of 1893, Dr. Park was appointed, in accordance with the recommendation, "Bacteriological Diagnostician and Inspector of Diphtheria."

The Health Board at that time determined to make use of bacteriological examinations for the diagnosis of diphtheria, not only in all cases admitted to the hospital wards, but also in all cases of suspected diphtheria occurring in the city where the co operation or consent of the

attending physician could be obtained. This action was determined on with a view to giving precision to the work of the Department in the prevention of this disease.

During the first weeks after the commencement of this work the number of cases examined weekly was comparatively small, but this number has continually increased until, during the last few months, a large proportion of all the cases of suspected diphtheria occurring in the city have been subjected to bacteriological examination.

As the scope and extent of the work increased, it was found it would be impossible for Dr. Park to perform all of the actual bacteriological examinations, and Mr. Alfred L. Beebe, inspector of bacteriology in this Department, was assigned to assist him.

From the beginning those in charge of the work had little doubt of its ultimate success, but they appreciated the importance of the change that was made in the sanitary management of this disease, and did not feel assured that the physicians of this city would quickly avail themselves of the opportunities thus afforded to them.

At first, as far as possible, the inspector of diphtheria, or special inspectors assigned to this duty, visited physicians who reported cases of diphtheria and explained to them the purposes of the work. These inspectors made inoculations from cases only after a request or the specific consent of the attending physician had been received. After a short trial, however, it was evident that a large majority of the physicians of New York would be glad to avail themselves of the assistance offered by the Department. A further step was then taken to increase the facilities for such examinations. A number of depots were established throughout the city (these now number about forty) where culture-tubes and the directions required for making the inoculations could be obtained by physicians without charge. These depots were generally established at drug stores, at convenient points, and arrangements were made for the collection of the tubes left at these depots by Department collectors late in the afternoon of each day. For convenience and safety in transporting the tubes, small wooden boxes, holding culture-tubes, were supplied from each of the depots. Each box contains all that is required for making a culture, *i.e.*, a culture-tube, a swab for inoculating it, and a blank for recording the name, address, etc., of the patient. Each box with its contents is known as "a culture outfit."

The following cards, giving directions for making the cultures and the addresses of the depots where tubes could be obtained, were also supplied with the tubes:

HEALTH DEPARTMENT.

WHITE, CENTRE, ELM, AND FRANKLIN STREETS.

DIRECTIONS FOR MAKING CULTURES IN CASES OF SUSPECTED DIPHTHERIA.

The patient should be placed in a good light, and, if a child, properly held. In cases where it is possible to get a good view of the throat, depress the tongue and rub the cotton swab gently, but freely, against any visible exudate.

In other cases, including those in which the exudate is confined to the larynx, avoiding the tongue, pass the swab far back, and rub it freely against the mucous membrane of the pharynx and tonsils. Without laying the swab down, withdraw the cotton plug from the culture-tube, insert the swab, and rub that portion of it which has touched the exudate gently but thoroughly back and forth all over the surface of the blood-serum. Do not push the swab into the blood-serum, nor break the surface in any way. Then replace the swab in its own tube, plug both tubes, put them in the box, and return the culture outfit at once to the station from which it was obtained.

A report will be forwarded the following morning by mail, or can be obtained by telephone, after 12 noon.

Culture Outfits can be Obtained from the Following Stations Free of Cost:

The diagnosticians, and later the medical inspectors of the Department, were supplied with leather pocket-cases, containing a number of culture-tubes and swabs, and were given instructions regarding the methods of making the inoculations. These arrangements being completed, the following circular was delivered, by special messengers, at the office of every physician in this city:

HEALTH DEPARTMENT.
No. 301 MOTT STREET, NEW YORK, July, 1893.

CIRCULAR OF INFORMATION CONCERNING THE USE OF BACTERIAL CULTURES FOR THE DIAGNOSIS OF DIPHTHERIA.

Recent bacterial investigations have shown that a considerable proportion of the cases of pseudo-membranous and exudative inflammations of the throat and upper air-passages, commonly considered as diphtheria, and having the anatomical appearances found in diphtheria, are not true diphtheria. These cases may be called pseudo- or false diphtheria.

It has also been shown that a considerable number of cases which are apparently false diphtheria prove on bacterial examination to be true diphtheria. While in true diphtheria the mortality is very high and the danger of transmission to others is great, in false diphtheria the mortality is low and the danger of infection slight. The differential diagnosis between true and false diphtheria can be made by bacteriological examination within twelve hours, while without this the differentiation is difficult or impossible.

The Health Department is now prepared to make use of bacterial cultures for diagnosis in all cases of suspected diphtheria occurring in the city, and desires that in every case either the physicians should themselves make the inoculations, or should authorize an inspector to make them. They should be made in every suspicious case at the earliest possible moment, for during convalescence the specific organisms often disappear from the throat, and the full benefit of a positive diagnosis is not obtained unless it is made early in the disease.

The inoculations are made by gently rubbing a cotton swab against the throat, and then drawing it over the surface of the culture-medium. When the physician desires to himself make the culture (and this is usually the better plan, for it can be done earlier and is more agreeable to the family), he can obtain, free of cost, a culture-tube and swab, and the simple directions necessary for their use, at any one of the druggists whose addresses are given. After the inoculation the tubes are to be returned at once to the druggist from whom they were obtained. The tubes will be collected by the Department every evening.

In cases where an inoculation has not been made by the attending physician, the medical inspector will make one, unless for any reason the physician requests that none be made when he notifies the Department of the case.

The diagnosis will be ready by noon of the following day. The attending physician can obtain this immediately by telephoning to the laboratory, or when this is not done, he will be notified by mail. Cases which prove to be false diphtheria will not be visited by the Health Department inspectors. Cases, on the other hand, which prove to be true diphtheria, will be subjected to the usual rules and regulations covering contagious diseases.

The materials required for making inoculations can be obtained from the druggists named, free of cost.

All communications on this subject should be addressed to Dr. Hermann M. Biggs, Chief Inspector Pathology, Bacteriology, and Disinfection, No. 42 Bleecker Street (Telephone "1191 Spring").

By order of the Board of Health,

CHARLES G. WILSON, *President.*
EMMONS CLARK, *Secretary.*

As soon as it was possible to still further enlarge the work, a new investigation was instituted. This was the determination, by bacteriological examination of secondary cultures from the throats of convalescent cases of diphtheria, how long the bacilli of diphtheria persist during convalescence.

After a sufficient number of examinations had been made to draw accurate conclusions, the following circular was printed, and ordered to be sent to the physician with the report of the result of the bacteriological examination of the first culture. In it, the important announcement is made that, in the future, no case will be considered free of the contagion of diphtheria until this fact has been established by culture test.

HEALTH DEPARTMENT.
DIVISION OF PATHOLOGY, BACTERIOLOGY, AND DISINFECTION,
No. 301 MOTT STREET, NEW YORK, 189—.

No. 42 BLEECKER STREET.

To Dr. ——.

SIR: During the last few months a series of investigations have been made in the bacteriological laboratory of the Health Department to determine how long the Loeffler bacilli remain in the throat after the disappearance of all false membrane in cases of diphtheria.

The results obtained are extremely significant, and have caused the Department to establish a new rule regarding the discharge from observation of patients who have suffered from diphtheria, and regarding the time of disinfection of the premises.

During the past three months 405 cases of true diphtheria have been subjected to repeated bacteriological examinations performed at short intervals during the course of the disease and during convalescence.

In all of these cases cultures were made at the beginning of the disease, again after the lapse of three or four days, and finally at short periods after the complete disappearance of the false membrane, until the throat was found to be free from the diphtheria bacillus. In 245 of these 405 cases the diphtheria bacilli disappeared within three days after the complete separation of the false membrane; in 160 cases the diphtheria bacilli persisted for a longer time, namely: in 103 cases for seven days, in 34 cases for twelve days, in 16 cases for fifteen days, in 4 for three weeks, and in 3 for five weeks after the time when the exudation had completely disappeared from the upper air-pa sages. In many of these cases the patients were apparently well many days before the infectious agent had disappeared from the throat. These results show that in a considerable proportion of cases persons who have had diphtheria continue to carry the germs of the disease in their throats for many days after all signs and symptoms of the disease have disappeared. No doubt the disease is largely disseminated by these persons who are apparently well, and who mingle with others while their throat secretions still contain the diphtheria bacilli.

These experiments have led the Health Department to adopt the rule, that no person who has suffered from diphtheria shall be considered free from contagion until it has been shown by bacteriological examination, made after the disappearance of the membrane from the throat, that the throat secretions no longer contain the diphtheria bacilli, and that until such examinations have shown such absence all cases in boarding-houses, hotels, and tenement-houses must remain isolated and under observation. Disinfection of the premises therefore will not be performed by the Department until examination has shown the absence of the organisms.

Secondary cultures, as in the case of primary cultures, may be made by the attending physician, if he so desires; otherwise they will be made by the inspector of the district in which the case occurs. This applies only to cases occurring in boarding-houses, hotels, and tenement-houses—not to those in private houses.

In this connection an interesting observation has been made showing that in diphtheria cases which have been subjected to frequent irrigation with antiseptic solutions from the beginning of the disease the bacilli disappear more rapidly than in those in which such irrigations have not been employed. The Department would feel grateful for any data which the physicians of this city may furnish as to the treatment employed in each case, in order that more reliable conclusions may be reached as to the best mode of treatment.

It has been also found, that occasionally when culture-tubes are inoculated immediately after irrigation of the throat with antiseptic solutions, the cultures do not show any Loeffler bacilli, although subsequent examinations may demonstrate their presence. This observation should be noted in making inoculations.

Very respectfully,
HERMANN M. BIGGS, M.D.,
Chief Inspector of Pathology, Bacteriology, and Disinfection.

Approved by the Board of Health.

CHARLES G. WILSON, *President.*
EMMONS CLARK, *Secretary.*

Is the place ready for disinfection if the culture is found free from diphtheria bacilli?

During the first few months, in order to test the results of the examinations and to make the liability to error as slight as possible, the following plan was adopted:

All cases which yielded no diphtheria bacilli were turned over to special inspectors, who made, if possible, in every case, a second culture, and followed up the patient for some time after recovery. From the information thus secured, the bacteriologists of the Department were able to decide more and more surely how far they could base an absolute diagnosis on the examination of a culture.

In the first circular issued, the Health Board announced that cases which proved on bacteriological examination to be false diphtheria, would not be kept under the observation of the Department. Some physicians who heartily approved of the work of the Department in its treatment of diphtheria, believed that in this step it had proceeded too far, and that the false cases, though less contagious than the true, were yet sufficiently so to render isolation and supervision necessary. From a large experience the Health Board believed these cases were so rarely serious in their results, and were so little, if at all, contagious, that visits from Department inspectors were unnecessary. Nevertheless, before issuing the circular, one hundred and fifty consecutive cases were investigated, all sources of contagion sought for, and the patients kept under observation for two weeks after convalescence. In none of these was isolation or disinfection required. The evidence obtained so completely confirmed the previous experience that the Health Board felt justified in concluding it was unnecessary to exercise any sanitary supervision over cases of false diphtheria. Those who believe they have met with cases of false diphtheria which have been the cause of severe or fatal illness in others, have probably either mistaken the nature of the first case, or have been dealing with some other infectious disease (such as scarlet fever), in which the inflammation of the throat is merely a secondary lesion.

In order to make the possibility of error in the routine work as small as possible, for some months the following circular has been mailed to physicians with every report:

HEALTH DEPARTMENT.
DIVISION OF PATHOLOGY, BACTERIOLOGY AND DISINFECTION,
No. 42 BLEECKER STREET.

NEW YORK, February 20, 1894.

TO PHYSICIANS: It is the earnest desire of the Health Department that the service in the bacteriological diagnosis of diphtheria be made as perfect as possible and as useful to physicians as it can be made. When cultures are left at any of the depots before 4 P.M., it is the aim to return in every case a report of the bacteriological diagnosis on the following day. Reports are mailed before one o'clock, and should be delivered to the physician before the last mail of the day. Earlier reports can be obtained by applying to the Laboratory by telephone (No. 1191 Spring) after 12 M.

When the bacteriological diagnosis does not harmonize with the clinical facts and the history, as shown by antecedent or subsequent cases of diphtheria, and where there are any defects or reasons for complaint regarding the service in any respect, physicians are earnestly requested to report these promptly to the Chief Inspector, Dr. H. M. Biggs, No. 42 Bleecker Street. Knowledge of defects in the service can only reach the Department through such reports, and the service can only thus be improved and perfected.

Physicians are requested to read carefully the accompanying circulars describing the character of the work and method of procedure, and to follow exactly the instructions given. Thus uniformity in method and accuracy in results will be insured.

HERMANN M. BIGGS, M.D.,
Chief Inspector of Pathology, Bacteriology, and Disinfection.

Depending on the results after the examination of primary cultures, one of the following blanks is filled out and mailed to the attending physician before 12 M. of the day following that on which the culture was made:

NEW YORK, 189—

Dr. ——

DEAR SIR: The examination of the cultures made by inoculating the tubes with the exudation from the throat of on shows the presence of the diphtheria bacilli.

The case is therefore one of true diphtheria.

.....
Chief Inspector.

.....
Inspector of Diphtheria.

HEALTH DEPARTMENT.
DIVISION OF PATHOLOGY, BACTERIOLOGY, AND DISINFECTION,
BACTERIOLOGICAL LABORATORY, 42 BLEECKER STREET.

NEW YORK, 189—

Dr. ——

DEAR SIR: The examination of the cultures made by inoculating the tubes with the exudation from the throat of on does not show the presence of any diphtheria bacilli.

The case is therefore not true diphtheria,[1] but pseudo- or false diphtheria, and no further cognizance will be taken of it by the Department unless by the special request of the physician in attendance.

.....
Chief Inspector.

.....
Inspector of Diphtheria.

HEALTH DEPARTMENT.
DIVISION OF PATHOLOGY, BACTERIOLOGY, AND DISINFECTION.
BACTERIOLOGICAL LABORATORY, 42 BLEECKER STREET.

NEW YORK, 189—

Dr. ——

DEAR SIR: The examination of the cultures made by inoculating the tube with the exudation from the throat of on does not admit of an exact bacteriological diagnosis, for the following reasons:

A. The inoculation was made at so late a period in the disease that it is possible that the diphtheria bacilli, though now absent, were at an earlier time present.

B. The growth on the culture media was so scanty that it is probable that the inoculation was not properly made, or that some antiseptic had been applied to the throat shortly before obtaining the material for inoculating the tube.

C. The culture media was badly contaminated.

D. The serum in the tube was too dry to permit of the growth of the diphtheria bacilli.

a. Another culture is requested.

b. The case will be treated as one of diphtheria.

c. The case will be treated as one of false diphtheria unless the physician in charge of the case requests otherwise.

.....
Chief Inspector.

.....
Inspector of Diphtheria.

After the examination of each secondary culture and depending on the result of the examination, one of the following blanks is filled out and forwarded to the attending physician and to the Chief Inspector of Disinfection:

Laboratory No.

HEALTH DEPARTMENT.
DIVISION OF PATHOLOGY, BACTERIOLOGY, AND DISINFECTION.
BACTERIOLOGICAL LABORATORY, No. 42 BLEECKER STREET.

NEW YORK, 189—

Dr. ——

DEAR SIR: The examination of the culture made by inoculating the tube from the throat of on shows the presence of the diphtheria bacilli.

The case is therefore not yet ready for disinfection, but needs a further culture.

HERMANN M. BIGGS, M.D.,
Chief Inspector.

WILLIAM H. PARK, M.D.,
Inspector of Diphtheria.

Laboratory No.

HEALTH DEPARTMENT.
DIVISION OF PATHOLOGY, BACTERIOLOGY, AND DISINFECTION.
BACTERIOLOGICAL LABORATORY, No. 42 BLEECKER STREET.

NEW YORK, 189—

Dr. ——

DEAR SIR: The examination of the culture made by inoculating the tube from the throat of on does not show the presence of any diphtheria bacilli.

The case is therefore ready for disinfection, if the other circumstances allow.

.....
Chief Inspector.

.....
Inspector of Diphtheria.

[1] This conclusion is based on the supposition that the directions have been properly carried out and that the inoculation was made before the commencement of convalescence. After convalescence is established the bacilli often disappear from the exudate.

In the beginning of this work some physicians familiar with bacteriological investigation feared that it was not safe to trust the inoculation of the culture-tubes to physicians unskilled in bacteriological methods. The Department has found, however, that physicians may as a rule be relied on to carefully follow the simple directions as to the procedure required to make satisfactory inoculations of culture-tubes, and that the diagnoses based on the bacteriological examinations of such tubes can be safely accepted.

A communication was forwarded to the Health Board in November, 1893, recommending the adoption of an amendment to the Sanitary Code, which should include so called "membranous croup" with the contagious diseases concerning which the Department requires reports from physicians. This recommendation was based on the results of the bacteriological examinations of a considerable number of cases of croup, which showed that more than eighty per cent. of them were really cases of laryngeal diphtheria.

The detailed results of the work for the first year, both as to the bacteriological examination of suspected cases of diphtheria and the experimental work on questions allied to this, are contained in the appended report from the Bacteriological Laboratory, by Dr. William H. Park, Bacteriological Diagnostician and Inspector of Diphtheria, and Mr. Alfred L. Beebe, Inspector of Bacteriology, by whom this work has been performed.

There is also appended a report from Dr. A. Campbell White, Resident Physician at the Willard Parker Hospital, detailing the results obtained from an important series of investigations made to determine the influence on the persistence of the diphtheria bacilli of systematic irrigation of the throats of diphtheria patients with various antiseptic and cleansing solutions. The results are not as satisfactory as had been hoped for.

The question is naturally and properly asked, as to what influence this work has had on the prevalence of diphtheria in this city? In reply to this it can only be said that there has been a large increase in the number of cases of diphtheria occurring during the last year in many of the large cities of the world, and New York has suffered from this semi-epidemic influence, but to much less extent than some other cities. The number of cases reported weekly had begun to increase before the initiation of this work and this increase has continued notwithstanding it. The total number of cases reported during the last year has been considerably greater than during the previous year, but the number of cases apparently occurring in the city has been unquestionably increased by the more universal reporting of cases by physicians. It is, of course, impossible to say how much greater the real increase of cases would have been without the work which has been carried on by the Department, and the inability of the Department to completely control the spread of the disease will be readily understood by reference to the description of the methods of dissemination of the disease contained in the detailed report from the Bacteriological Laboratory appended herewith.

It may be said in conclusion that the success of this new departure of the Health Department of New York city has far exceeded all anticipation. The Health Board was the first sanitary board in the world to officially adopt and provide for the making of such bacteriological examinations, and the course of the board in this matter has been carefully watched by sanitary authorities in various parts of the world. Constant inquiries have been made as to the conduct of the work, and many requests for circulars and for information as to the manner in which the work is carried on have been received. Numerous

representatives of other health departments have been instructed, in the Bacteriological Laboratory, in the methods employed; and the plan of work, as devised by this Department, has been adopted, without modification, by the health authorities of many other cities.

THE SURGICAL TREATMENT OF SURGICAL KIDNEY.

By ROBERT F. WEIR, M.D.,

PROFESSOR OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; SURGEON TO THE NEW YORK HOSPITAL, ETC.

SUPPURATIVE pyelo-nephritis, suppurative interstitial nephritis, and surgical kidney are the ordinary names given to a disease which, originating, as a rule, in the bladder, generally affects, according to Delafield,[1] both kidneys. This observer gives the following excellent, though brief description of the pathological changes usually found in this affection.

"The pelves of the kidneys are congested and coated with pus or fibrin. The kidneys themselves are swollen, congested, and studded with foci of pus The smallest foci are not visible to the naked eye, but with the microscope collections of pus cells are found between the tubes, with swelling and degeneration of the epithelium, within the tubes. The larger purulent foci look like white streaks or wedges running parallel to the tubes, and are surrounded by zones of congestion. The larger abscesses replace considerable portions of the kidneys. The ureters are in some cases inflamed, their walls thickened, and their inner surface coated with pus or fibrin. The bladder presents regularly the lesions of acute or chronic cystitis. It is a very fatal disease. So far," continues Delafield, "as I know, all the cases die, and when nephritis is once established there is no further control over thecase."

This may be said to represent very fairly the impression common to the profession from various authoritative sources concerning this very frequent complication of acute or chronic inflammatory and obstructive affections of the bladder. The following case, however, shows that some modification may be made in the foregoing statement concerning the prognosis of such cases.

Henry W. D——, a young man, twenty-five years of age, was admitted to the surgical wards of the New York Hospital on April 2, 1894, with the history that four years previously he had had pneumonia, which was followed a few months later by an attack of scarlet fever, accompanied by nephritis. From this latter complication albumin and casts persisted for a considerable length of time afterward in the urine. He never entirely regained his health, though previous to this time he had been noted as an athlete. About one year ago he had a mild attack of urethritis, which did not extend to the deep urethra. Three months ago he contracted a second and severe urethritis, which invaded the bladder. He suffered from an increased frequency of urination, with tenesmus and a discharge of blood and pus. Gonococci were present in this discharge in great numbers. This trouble subsided gradually under local treatment, which consisted of irrigation, at first daily with a one per cent. solution of creolin, then with a quarter of a grain solution of silver nitrate every third day, supplemented by irrigation twice a day with a quarter of a grain solution of zinc sulphate. During the last month applications had been made to the posterior urethra with a Keyes syringe. Two weeks later urination had so far improved that the bladder was evacuated but once in every four hours. The urine was acid in reaction; specific gravity, 1024; but still contained considerable pus and about ten per cent. of albumin. About twelve days prior to his admission into the hospital, without any assignable cause, the last instrumentation being nearly a week anteriorly, he developed a chill, succeeded by a temperature of 101° F., with prostration, vomiting, and diarrhœa. These symptoms subsided on decubitus, with fluid diet, subnitrate of bismuth, and oxalate of cerium.

[1] Letters on Practical Medicine and Pathology, 1890.

Eleven days ago, that is, the next day to the above attack, pain in the loins was first complained of and was of the character of lumbago. The next day he suffered a relapse of his febrile symptoms, the temperature rose to 103° F., and the pain in the back increased in severity. Tenderness could be readily excited by bimanual examination in the renal region, particularly on the right side. By the rectum the bladder was normal, nor was there any increase in the frequency of urination. Two days later the temperature had fallen to 101° F.; but the lumbar tenderness increased and was more marked in the right loin and hypochondrium. He was then admitted to the New York Hospital on the medical side, where, after a temporary stay, he was transferred to the surgical division.

During the seven days that elapsed between his entrance into the hospital on March 28th, to April 4th, when surgical interference was resorted to, he had four chills, the temperature rose daily, ranging between 103° and 105½° F. When seen by me April 3d, in consultation with Dr. Peabody, the physician then on duty in the medical ward of the hospital (to whom the case had been first referred as one of severe typhoid fever, but by whom this diagnosis was speedily rejected), the patient's condition was a most serious one. The urine was discharged in quantities ranging from fifty to sixty ounces per diem. It was moderately turbid, contained pus, and was voided without much bladder irritation; pulse, 116 to 120. Pain was complained of in the right lumbar region. Pressure in that place alone, or conjoined with pressure in front, gave rise to a decided tenderness. This was not experienced on the left side. Some tenderness was, however, found on both sides, but after repeated trials it was found to be confined to the spinal muscles themselves. For when pressure was brought to bear directly over the region of the kidney external to the erector spinæ muscles, no pain was developed on the left side but considerable on the right side. Moreover, by bimanual examination on the right side, it was thought that an enlargement of the kidney could be made out. My own impression at that time was that the patient had probably an abscess of the kidney, or possibly several such, of considerable size. I did not think that he had the ordinary condition known as the "surgical kidney," because of the single-sided nature of the symptoms and its somewhat slow development. I, however, felt that there was urgency in his case and that an exploratory incision should be made down to the kidney and this organ opened in the hope of evacuating the contained matter. It was considered advisable in the condition of the patient, to fully acquaint his family of the great risk the operation might bring the patient into and the possibility of not affording him any benefit whatever if it should be proven to be a general renal infection. Any hope of relief, however, was grasped at by them, and under ether anæsthesia on April 4th, with the patient in the usual position, an incision was made just outside the quadratus lumborum muscle from the twelfth rib down to the crest of the ilium, and thence forward to and a little above the anterior superior spine of the ilium, the flap raised up and the kidney exposed. It was found to be twice its usual size. It was irregularly and deeply congested, and also irregularly swollen, particularly so on its inferior surface. Puncture in two or three directions with the aspirator needle gave no evidence of pus. An incision was then made along its external border, about its middle, and revealed immediately the nature of the disease. This incision, an inch in length and nearly an inch in depth, disclosed on its two sides numerous miliary abscesses and streaks of hemorrhages and pus which showed that we had to do with an ordinary surgical kidney. The rather desperate venture was, however, taken of advising and practising an extirpation of this infected and infecting kidney, basing this action upon the assumption that no symptoms pointed decidedly toward an invasion of any great extent of the left side.

With the ample room afforded by the incision just described (König's) the kidney was rapidly enucleated, heavy silken ligatures being passed around it, and its pedicle secured. The kidney was separated beyond the ligature, the wound packed lightly with weak iodoform gauze and the lower edge of the wound secured by silkworm gut sutures.

Immediately after the operation the temperature dropped from 105° F. to 99° F. and remained subnormal the three following days, with a moderate amount of vomiting. From the fourth day onward the patient made an uninterrupted and rapid recovery, being discharged from the hospital on April 20th, three weeks later. At that time, his urine, though not absolutely free from pus cells, was nearly normal. However, it contained still, on bacteriological examination, a few but a diminishing number of the rods of the colon bacillus, but no treatment was thought advisable, except that he should spend as much time the present summer in the open air as the ordinary rules of hygiene demanded.

The report of the pathologist of the hospital, Dr. Ferguson, on the removed kidney, is that it measured 14 × 6½ × 4 ctm. and that its capsule was thickened and adherent. Various cut surfaces beside the exploratory incision showed a great number of abscesses of miliary size in the pyramids and also in the cortex. The kidney substance also contained a large number of minute hemorrhages; the pelvis was dilated, its mucous membrane contained many small hemorrhages but was otherwise pale. No gonococci were found on bacteriological examination, but numerous colonies of the bacillus coli communis were developed under culture.

I will simply add to the foregoing history that though the literature of the surgery of the kidney is now so large that it may already include the consideration of this question of surgical kidney in its application for relief by surgical measures, yet I have so far failed to find any similar cases; carrying my investigation in the Index Medicus, however, only as far back as the year 1886.

The first question that comes to the mind of every surgeon reading this report is, How often may such a fortunate condition of affairs be found in cases of surgical kidney? I had, of course, known that surgical kidney was occasionally one-sided, but believed this to be a very rare occurrence, but its frequence was unknown to me. An imperfect endeavor has nevertheless been made to get some further light upon this latter point. I cannot pretend to have made anything more than a cursory examination for data in this direction, but it is not difficult to place the fact squarely in position that this form of suppurative nephritis may not infrequently be confined to but one side. For instance, Goodhart, in an article in Guy's Hospital Reports of 1874, collected 270 cases of deaths from urinary disorders, and in these were 130 cases of surgical kidney, as follows: In 100 strictures, 41 of suppurating kidney, of these 3 cases one side only affected. In 27 prostatic hypertrophy, 20 suppurating, 1 confined to one side. In 14 cancers of the bladder, 6 suppurating, 2 confined to one side. In 44 stone, 31 suppurating, 8 to one side. In 29 cancer uteri, etc., 6 suppurating, 0 to one side. In 56 from paraplegia, 26 suppurating, 56 to one side. This makes an average of 14½ per cent. for one-sided renal infection.

In the article whence these statistics were taken, however, the condition of surgical kidney is more or less mixed up with single or multiple abscesses of considerable size. Therefore, its value is not as great as it would otherwise be. I have taken pains, therefore, to collect from the records of the New York and of St. Luke's Hospitals, in this city, forty-five cases, of which six were one sided in their lesions, and also from the brochures of Malherbe, "De la Fièvre dans les Maladies des Voies Urinaires," 1872, and of Bazy, "Des Lesions des Reins," etc., 1880, other cases, in six of which one-sided lesions existed, which make a total of 71 well-defined, undoubted acute cases of surgical kidney. Of these both organs were affected in 59 cases and only one organ in 12 cases, that is to say there were about twenty per cent. that could be attacked, other things being equal, surgically. We can, therefore, feel more hopeful in such conditions than, I must admit, I certainly have been in the past.

From the manner in which the kidney substance pouted out beyond the divided capsule after the first incision was made into this organ I could not but feel on reflection that even in those cases, perhaps, where both sides were involved, something might be done for the relief of tension as well as for the egress of pus, etc., by means of a free incision similarly made into the kidney substance.

Hence, in conclusion, with the happy experience of the present case I would consider it hereafter justifiable, if the patient's general condition would warrant it, in a case of acute septic invasion of the kidneys to make on one or both sides an exploratory incision not only in the hope of relieving the acute interstitial invasion, but also of perhaps encountering a larger and well defined focus of pus, which pathological condition cannot always, it is fully understood, be readily discriminated from the more dangerous lesions of the veritable surgical kidney. Should the symptoms point, as in the case just narrated, to one kidney only, or should a double exploratory incision show the same result, a nephrectomy may with some hope now be resorted to.

END TO END INTESTINAL ANASTOMOSIS BY THE USE OF MURPHY'S BUTTON, WITH REPORT OF CASE.

By WILLIAM W. STEWART, M.D.,

COLUMBUS, GA.

On February 27, 1894, I was asked by Drs. C. L. Williams and R. E. Griggs to operate upon a case of strangulated hernia which that day had fallen into their hands as city physicians.

History.—E——, male, aged twenty-three; occupation butcher. Well developed, six feet in height. From earliest recollection had been troubled with an oblique inguinal hernia of left side, which previously had been easily controlled by the wearing of a truss. February 25th arose at 6 A.M., and before applying truss bathed and dressed. While thus occupied hernia came down, causing with its descent some pain, which attracted his attention. On trying to reduce hernia he found he was unable to do so, and summoned medical assistance. Opiates, cold and hot applications, taxis, and the usual rôle of methods of relief were tried successively by his attendants with no avail. This was continued till the morning of the 27th, when case was reported for the hospital. Patient was immediately removed by the order of Drs. Griggs and Williams to the hospital, where at 3 P.M. I first saw him. Condition at that time was one of profound shock. Limbs flexed upon the abdomen. Facial expression pinched and drawn. Some tympanites; pulse, 145 to 160; respirations quick and jerky; constant hiccough; vomiting persistent prior to entering hospital.

At 3.30 P.M., in the presence of Drs. C. L. Williams, J. H. McDuffie, and J. P. Martin, of Birmingham, Ala., and assisted by Drs. George J. Grimes, R. E. Griggs, and McD. Blanchard, the operation was performed. Ether was administered; site of operation was well scrubbed with tincture of green soap and hot water and shaved, then washed with bichloride solution of 1 to 1,000. An incision was then made from a point just above external ring to bottom of scrotum. Tissues were swollen and œdematous; sac being opened, there gushed out three to four ounces of blood-stained serum, having some bad odor, which brought into view a large purplish black mass adherent to bottom of sac, which proved to be omentum. This being drawn to one side, a mass of small intestine about ten inches in length was exposed. Intestine and omentum both proved gangrenous and extremely friable. Internal and external ring were then both incised, freeing the strangulation and giving more room for operative procedure. Gangrenous intestine

was drawn well out, and a shoemaker's stitch with a knot in each stitch was taken through mesentery along entire length of gut to be excised, thus controlling perfectly all hemorrhage. Intestine was then grasped by two assistants just past the gangrenous demarcation between thumb and forefinger, and well compressed. Then with scissors ten inches of gangrenous gut was excised. A purse-string suture was then introduced into both ends

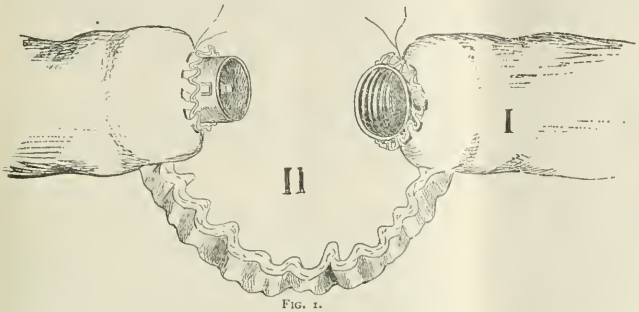

Fig. 1.

of gut and Murphy's button adjusted, by which both peritoneal surfaces were brought into perfect apposition. Sutures were then placed, closing gaps in mesentery. Gut was carefully cleansed and dropped back into abdominal cavity.

Attention was now turned to the omentum, which formed the principal bulk of the hernial mass, eighteen inches of which proving gangrenous and friable, its removal was necessary. Same ligature stitch was introduced as was used in mesentery, and mass excised. Sac was then carefully freed and transfixed with silk ligature and stump sewed into wound. Wound was closed with silkworm-gut sutures and tight compression-bandage applied. Condition of patient from first to last was very bad, radial pulse often becoming almost imperceptible, calling for frequent hypodermic injections of strychnia, nitroglycerine, and whiskey. After being placed in bed a

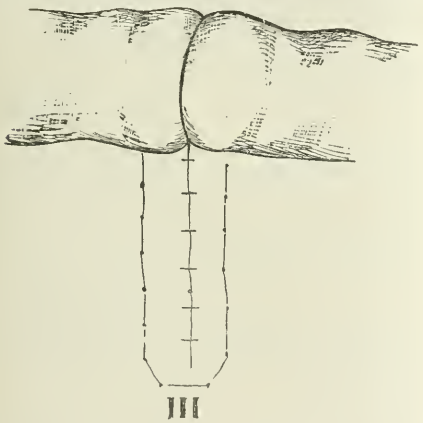

Fig. 2.

hot, normal salt solution enema was given, which quickly raised volume of pulse.

By morning patient reacted nicely and continued comparatively free from pain. Pulse remained high, 140; temperature ranged from 99° to 100° F. till the third day, when it reached normal.

On the third day high enema was given, which was followed by copious action. These were continued every second day, each time being followed by passage of fecal matter till the thirteenth day, at which time the button was passed and immediately followed by three large movements slightly streaked with blood, since which no blood has appeared, bowels continuing to move twice daily. Abdominal wound healed kindly; wound in scrotum did not, as some of the cellular tissue became gangrenous and was removed, this being caused by the strangulated condition in which it remained for so long. Diet was restricted to milk till the fifteenth day.

This method of end to end intestinal anastomosis has advantages so patent that it immediately recommends itself to every abdominal surgeon. Its advantages are: 1. The rapidity with which anastomosis can be performed. 2. The normal continuity of the lumen of the gut is retained. 3. The perfect apposition of peritoneal surface under gentle pressure, thereby guaranteeing prompt and perfect union. 4. Apposition produced prevents perfectly escape of gases into peritoneal cavity. 5. When button passes there is nothing left in intestinal coat other than normal tissues.

Dr. Murphy, by his genius, has made all abdominal operators his debtor through the gift of his "button," a perfect mechanical contrivance which changes often

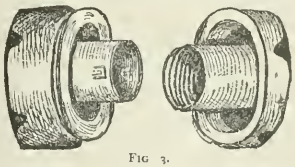

Fig 3.

extremely difficult and hazardous procedures to rapid and much safer operations.

The button, as now manufactured, is of nickel plated brass. The material used in its manufacture can, I think, be improved upon by substituting aluminum for the brass, thereby reducing its weight, which will facilitate its passage from the intestine.

SOME PRACTICAL OBSERVATIONS ON SO-CALLED MALARIA BEING A WATER-BORNE DISEASE.[1]

By W. H. DALY, M.D.,

PITTSBURG, PA.

The writer has for the past twenty or more years spent probably an average of two months annually in the recreative sports of the field, forest, and stream. The largest proportion of these holiday jaunts have been passed in the lowlands, or in the swamps of the lake-sides or sea-side, in the pursuit of wild fowl shooting. Many, if not most of these regions were, and are generally admitted to be, intensely malarial in character, notably the vast Kankakee swamps in Indiana.

In former years, before the writer had noticed certain conditions, and used certain precautions, he was subject to malarial disease of a continuous or recurrent type, clearly traceable to his having drunk the shallow well- and swamp-water of these regions.

Observations and studies on the subject, and investigations made in various districts from Manitoba to Louisiana, and all along the southern coast of the Atlantic Ocean, and of Cuba, Yucatan, and other districts in Mexico, lead the writer to the conclusions that so called malarial disease is not easily, if at all, contracted by inhaling so-called malaria or bad air, of the low, swampy, or new lands, but it is distinctly, if not almost exclusively, due to drinking the water that has come into contact with, and become infected with the malarial germs or in-

[1] Read before the meeting of the American Climatological Association, in Washington, May 29, 1894.

fusoria that exist in the earth and waters of the swamp and lowlands. This germ does not ordinarily, if at all, float in the air during the day, nor does it find easily a vehicle in the fog or vapors of the night.

Indeed it is difficult to understand how one is to avoid the night-air, even if it is conceded to be deleterious—a conclusion I much doubt. Does any other air than night-air exist at night? Is it possible to breathe any other? Is there any habitation sufficiently sealed against the outside air to make the breathing of outside night-air impossible?

I understand the United States Navy Department years ago made, and they may still, for aught I know, make, a point of advising the anchorage of war vessels in streams and waters of malarial districts so as to avoid the air-currents from the swamps near by, lest the air, laden with poison, should be inhaled by the officers and sailors.

I will venture to say that no air from the foulest swamp can be more deadly than the foul air that is produced by the emanations from the air passages, and from effete matter from human beings crowded into the hold of a ship. That sort of air is indeed malarial, while the swamp air I believe to be comparatively safe and wholesome, but of the swamp water beware for any other purpose than ablution.

I am fully aware that in taking the ground I here occupy I may be considered to be too radical, and that my position may be regarded as untenable. If so, I can only answer that every observing medical man must and is bound to tell honestly and fairly what he has gathered from his own experience, observation, and studies, and it must be considered that my observations have been prolonged, extensive, and fairly intelligent, and made not, so to speak, second-hand, but personally and upon the ground in districts distinctly malarial, and that during the years that I and others had been careful to avoid the mists and fogs of the malarial regions, as well as the out-door night-air, but all the while using the surface-, swamp-, or shallow well waters for drinking, I, as well as others of my friends, suffered from malaria, so called; but later on, and during the past twelve years, while abstaining from drinking the surface- or well water, and with the utmost freedom of exposure to the out-door night-air, fogs, rain, and mists, at all times, night and day, we have enjoyed complete immunity.

Whoever has shot wild fowl knows full well that the best opportunities come to a sportsman amid storm and rain, with the early mists of the morning, and when the marshes are redolent with the vapors of the evening, just at nightfall, when the wild fowl are flying to and fro, seeking their favorite haunts in the marshes to sleep.

Then there is the journey of miles homeward to the club-house, farm-house, or camp, in the small ducking-boat, that brings one to the fireside possibly not earlier than eight to ten o'clock at night, so that exposure is positive, and close to the marsh and water, as one is sitting in a small boat.

I mention the foregoing as relevant, since medical men are still the readers and learners from the classic text-books of Watson, Tanner, and Niemeyer, not to speak of many others.

Tanner says, in his most attractive style: "It is worth remembering that malarial districts are most dangerous at night, and that this poison lies low, or, as Dr. Watson says, 'loves the ground.'" And Dr. MacCullach says: "It is a common remark in many parts of Italy, that as long as laborers are in an erect position they incur little danger, but that the fever attacks those that sit or lie on the ground."

All of the older and most of the new text books lay stress upon the strictly malarial feature of the disease, that is to say, that the poison is breathed into the system. Some of the newer writers, it is true, give some prominence to the source of contagion, from drinking the infected land- or swamp-water, but still adhere to the belief in the medium of the air as a chief or equal source of infection. This latter belief is a gross fallacy in my opinion, and will not stand the test of practical proof, if the factor of drinking land- and swamp-water is eliminated.

In recent years, through the digging up and renewing of the aqueducts, which for centuries had supplied the city of Rome with drinking water, it was discovered that many of her wealthy and leading citizens had, during the period of her grandeur and decadence, actually been guilty of clandestinely draining the sewage from their country and suburban villas into the very aqueducts that supplied the city and their fellow citizens with drinking-water.

Can there be a greater example of public degradation, and can any evidence be stronger than this, that a larger part of the Roman fever, which is unmistakably malarial, has been due to contaminated drinking-water rather than to infected air?

As I say, during these earlier years that I and others of my sportsmen friends drank freely from the running brooks and streams and from the swamps, we also endured for the sake of the sport of shooting wild fowl, an occasional shake with the ague and many of the other disagreeable symptoms that, while they do not amount to an actual chill, make one feel about as wretched as it is possible for one to feel and go about. And I and the others were all the time taking heavy doses of quinine as an antidote. In fact, no trip was ever taken to the swamp for wild fowl without plenty of quinine and a little whiskey.

But during the past twelve years, and since we have avoided drinking the surface-water, and, when it was possible, even the deeper well-water of the region except after boiling the same, I have been quite free, as have been others of my friends whom I have advised.

If one cannot get boiled water any other way, it is well enough to take the water that has been boiled in a brewery, viz., in form of beer.

It is now generally conceded that the malarial germ is the cause of the fever. Lemaire, Klebs, Crudeli, and others have isolated certain forms of bacillus, which they believe to be specific of malaria. Laveran first, and Richard and Marchiafava, and Cella, also found in the blood three forms of protozoa, one of which particularly produced intermittent fever by inoculation. The germ is infusorial, and exists in the water and soil.

E. Maurel, in the *Semaine Médicale*,[1] announced to the French Association for the Advancement of Science, that it is always easy to distinguish a healthy from a malarial soil.

The water from the malarious districts always contains numerous micro-organisms, some of which are possibly Laveran's corpuscles in an early stage of their development, but it is not yet certain that the germ has been isolated outside of the human body.

In regard to the real value of Laveran's corpuscles in the production of malaria, he himself believes them to be indirectly concerned in the production of the infection, although their relation to it has not been absolutely demonstrated. It is probable, according to Rougette,[2] that the malarial microbe gives rise to symptomatic fever by reason of its activity in producing leucomaines. During the access of fever the microbe is eliminated by natural emunctories.

The liver is a destroyer of leucomaines;[3] but, as my paper is upon the question of the manner in which the so-called malarial infection enters the human body, whether through the air-passages, or the digestive tract by means of drinking-water, I must not wander into other phases of the subject. I am firmly convinced that farther investigation will as surely lead us to the knowledge that so called malaria is, strictly speaking, a water-borne disease, as it is that we are now being led to the right conclusion, by Ernest Hart and others, that chol-

[2] L'Union Médicale.
[3] Annual Universal Medical Sciences, 1888.

era is also a water-borne disease; and it is our duty to educate the profession, and the public, especially those who make up the population of the malarial districts, that it is the water they drink, and not the air they breathe, that decides whether they will suffer from malaria or not.

It is a great pleasure to have come into contact with many of the intelligent medical men, who practise in the southern and malarial districts of our country, whose beliefs are far in advance of the vague and obsolete views of many of our writers of text-books. If there were as many such men in our profession as there ought to be, the use of quinine as an antiperiodic would soon become unnecessary. In fact I regard the malarial type of fever, in the United States at least, as clearly preventable as any other disease that we have to deal with, and by the simple method of drinking only carefully collected and uncontaminated rain-water, which, as a simple precaution, might be boiled.

I have observed on some of the plantations of the South, that among certain cattle and horses that have been shipped from the North for breeding purposes, many of those that were turned out on the marshes to drink the surface-water sooner or later sickened and died with what was known as climatic fever (malarial); but the animals that were kept stabled, and drank only the deep well- and cistern-water, would thrive as well as they did in the North.

In the *British Medical Journal* of October 21, 1893, Oswald Baker, surgeon of the British Army, writes that on the steamer Scindia, which sailed from Bombay for Marseilles on August 5, 1893, there occurred several cases of acute malarial fever that were, from the account given by Mr. Baker, clearly traceable to the drinking-water, which was taken on the ship at Bombay, and not in any way due to the air that the patients breathed.

It is a pleasure to note in the medical journals—the great educators of those who write text-books—the accumulating testimony of careful observers, who agree with my observations and experience herein set forth.

In the MEDICAL RECORD of January 28, 1893, E. D. S. writes that five out of a family of six, adults and children, had suffered pretty continuously for the past six years with malaria (so diagnosticated by the best physicians), at times being quite seriously ill, with temperature 104° F. Quinine was administered. Seven months ago a Pasteur filter was introduced, and quickly every symptom of malaria disappeared. Another family had the same experience.

Dr. L L. Von Wedekind, U. S. Navy, in the MEDICAL RECORD of February 11, 1893, gives a history of some cases which indicate that to drinking the land-water was traceable the cause of malarial fever on the coast of southwestern Africa. The doctor says "that land-water is considered as a cause, and a prominently exciting cause, with naval medical officers," as is proven by the orders issued by medical officers of the different ships serving on the coast, prohibiting the use of native water for drinking purposes.

In the region about Elizabeth, N. J., some years ago, in conversation with some well-educated medical men—among others Drs. W. J. Lumsden and Oscar McMullen, who were and are careful observers, I learned that their outbreaks of malarial fever (fresh cases) usually occurred in the early autumn, following a period of rainfall and a few subsequent warm days, but new cases only occurring among those who drank the land-water.

The inhabitants who used the storm-water, carefully stored in clean cisterns, especially above ground, uncontaminated with the soil-water, are immune from the attacks, and while the disease during the past two years has presented some varying features to these gentlemen, such as catarrhal jaundice, of an endemic character, traceable to malarial influence, as well as other forms, there does not appear to be anything to controvert the evidence that these patients took their malaria in water, either as drink, or upon the leaves of the turnip-top, greens, kale, spinach, cabbage, or other vegetables that grow close to the ground and have surface water on their leaves. These vegetables are abundant and usual in the culinary supplies of the region.

One may ask, Why do not the New Yorkers and Philadelphians also get malaria from the same surface-water, dew, and moisture upon the leaves of these same vegetables, shipped from this productive region to those cities? The answer might well be that they do unless the leaves are well washed in uncontaminated running-water before being presented for use as table food.

Dr. R E. Boyken, of Smithfield, Isle of Wight County, Va., informed me that thirty years ago he had studied this subject, and had since induced as many of his patients and fellow-citizens of his county as possible to adopt the cistern-water as a beverage, and all those families who fell in with and followed out his views are of healthy and ruddy complexion and free from malarial disease, while those who continued to drink the land-water are subject to attacks of malarial fever.

That so called malaria is an autochthonous disease, finding its way into the human body through the food channels, there can be little or no doubt in the mind of the original and unfettered observers.

It is true we have not found what we know to be the malarial germ and isolated it outside of the human body, and we are not sure either that we have found the typhoid germ in the soil or in the suspected drinking-water; yet we are quite sure that we trace typhoid origin through these sources.

Let us eliminate the atmospheric factor in malaria by noting in each case if the soil-, surface-, or shallow well-water has been drunk by the patient. If this has been done, the case is obviously one that has been exposed to the infection in its most potent form. There can be no scientific question more strictly in the line, and touching the true object, of this learned Association than this, and it is to be hoped that in the future papers will be invited from those who have had an opportunity of observing data bearing upon this, the chief phase of this unsettled question.

We do not merely want a rehash of old dogmas from the text-books, or echoes from time-worn unfounded opinions, garbled by one so-called authority from an antecedent authority, but let us have the fresh and unbiased observations and views of the thousands of intelligent medical men who have the opportunity in their own neighborhoods to make original observations and report them.

Dr. W. J. Lumsden, of Elizabeth, N. J., recently wrote me that his case-books show that fully ninety-eight per cent. of patients who have suffered from malaria for the past ten years got their supply of drinking water from the dug wells of the region. Those inhabitants who used the water from driven-wells, thirty or more feet deep, have had an unmistakable improvement in health. A driven-well is made by driving an iron pipe with a perforated inlet down deep into the earth, through strata of clay or marl, which seals off the surface land-water. So it will be understood that the water from the driven-well is pretty securely sealed against surface-water by its small calibre and tight fit in the soil through which it penetrates.

Since writing this article I observe the growth of medical opinion is gaining strength along the lines and in the direction of the contention of this paper. The *Journal of the American Medical Association*, of May 12, 1894, contains the following:

"Dr. Richard H. Lewis, of the North Carolina State Board of Health, has prepared a circular letter for the medical men of his State, regarding the influence of well-water in the production of fever and ague. He gives a homely illustration in the recited history of two families who resided as next-door neighbors in one of the eastern towns of his State. The two families each contained two adults—father and mother—and seven children. The two families were friendly, but their homes were

sufficiently separated to require independent water-supplies for each. One family drank from what was regarded with pride as 'the best well in town,' the other of rain water caught in wooden tanks. The members of the first family were constantly sick with malarial disease of one kind or another. Those of the second never had even a chill."

It is the wish to build up a line of testimony of a like character, if such can be obtained through the medical men of North Carolina. To this end he has written the appended letter, giving an invitation to a co-operative study of the well-water origin of malarial diseases.

"Dear Doctor: The evidence that malarial diseases are introduced into the system in many, if not most, instances through the medium of the drinking-water, is to my mind conclusive. The water containing the germs, or plasmodia, is surface- or superficial soil-water. Those living in malarial districts who confine themselves to water from cisterns or wells driven or bored beneath the stratum of marl or impervious clay—in other words, beyond the water which soaks down from the surface—are to a large extent free from attacks. If the people of our eastern counties could be generally convinced of this fact, and thereby induced to act upon it, the health conditions of that really fine section would be revolutionized for the better. To bring this about is the object of the Board of Health. In order to do this, facts must be presented to them in the concrete—not by illustrations from 'Asia and Spasia and t'other side o' Hillsborough,' so to speak, but by instances from among their own neighbors. I write to ask you if you know any facts bearing on this subject, and if so, that you will write them to me in detail at your earliest convenience. Give me the name and post-office of the head of the family having the experience. If not personally familiar with the facts, send me the name and address, that I may write to him direct."

WATER IN DIET AND THERAPEUTICS.

By BRADFORD C. LOVELAND, M.D.,

CLIFTON SPRINGS, N. Y.

The subject of water in diet and in therapeutics is one which has engaged the thought of medical men more or less since the infancy of the art. Yet I fear it is to-day given very superficial attention by too many of the profession.

The Medical Record of March 3, 1894, gives a very interesting editorial on water, setting forth its ancient prestige, and undoubted worth in combating disease, but refers principally to its external use.

I might fill this paper with observations and experience as to its external use, but my object is to show its use in diet, and in internal medicine.

Among the earliest medical writers we find water praised in terms which could not apply to any other article of food, or remedy in disease.

Galen said: "Cold water quickens the action of the bowels, provided there be no constrictions from spasms, when warm water should be used.

"Cold drink stops hemorrhage, and sometimes brings back heat. Cold drinks are good in continued and ardent fevers."

In biliousness, plethora, obstinate ophthalmia, spasms, headache, gastric fever, hiccough, cholera morbus, he recommended tepid or warm water drinking.

Celsus recommended water in fulness of the stomach, headache, pains in the joints, diarrhœa, hemorrhoids, and in hysterical and hypochondriacal conditions.

Hoffman pronounced water a universal remedy. He asserts that "it is suited to all persons at all times."

Cheyne said, "Without all peradventure water was the primitive original beverage, and is the only simple fluid fitted for diluting, moistening, and cooling."

But enough quotations; suffice it to say that the internal use of water as a remedy has been prescribed and written upon, from the earliest times, by such men as Gregory, Londe, Sir John Ross, Lanzani, Drs. Currie, Forbes, and John Bell.

In the early part of this century Priessnitz, while using so many external water treatments, did not fail to see the great value of its internal use. And his followers, in the early-time "Water Cure" in this country used to prescribe the drinking of water in quantities which would seem to most of us to be incredible.

In the present time it seems more popular for physicians to prescribe some bottled water with a thrilling prophecy of rapid cure on the label, when, in reality, any good, wholesome water would do quite as much, or perhaps more, good; for patients will hardly drink enough to benefit them when it costs them from twelve to twenty-five cents or more a quart. And besides that, they will frequently abstain from drinking ordinary water because they have been ordered to drink *Wild Cat* Lithia Water.

What is the mission of water in the body?

Besides the object of relieving thirst, it acts as a solvent for, and an aid to the absorption of, all the digested food material, which it takes with it on its way to the blood.

The water in the blood forms a medium for holding in solution and suspension all the organic and inorganic compounds needed for the nourishment of the tissues, and also the effete materials on their way to the various excretory organs.

As the water filters out through the kidneys and the glands of the skin, again its solvent power is used, as it carries with it the urea, creatine, phosphates, sulphates, chlorides, and other useless materials from which the blood needs constant cleansing.

Should water, then, become deficient in the body from any cause, osmosis in every part must be impeded to a greater or less degree, as there are varying degrees of selective affinity for water in the different organs.

Perhaps the bowels are the first to suffer, becoming constipated from lack of moisture in the intestinal secretions; then the liver, the bile becoming thick. Next the kidneys suffer, being compelled to excrete too concentrated a secretion.

Too great concentration leads to precipitation of soluble ingredients, forming calculi, as gall-stones or renal calculi.

Then, too, we will find the digestive fluids are too thick and cannot accomplish their work well.

Another most serious consequence of lack of fluid in the blood is the congestions, both primary—from overwork of certain organs, as the liver and kidneys—and reflex—from nervous irritations, these commonly occurring in the head and spine.

The lack of fluid in the blood also predisposes to arterial degeneration with its accompanying evils, and the uric-acid diathesis may in part be traceable to such a cause, for the concentration of blood and secretions renders assimilation or oxidation more difficult and less perfect.

Then, again, the abnormally concentrated blood, with the retention of excrementitious material, acts as a slow poison, producing mental depression and other symptoms.

When there is a marked increase in the amount of water ingested for a few days, or even for a few weeks, it may be that the only apparent action is on the kidneys, but later the bowels and skin will show the effect by becoming more active.

That the blood may be changed by the judicious use of water, I have abundant evidence, as two or three cases will prove.

Case I.—July 8, 1893, Mrs. D——, aged thirty-five, came to me with the impression that she was anæmic from chronic malaria, complained that she felt unreasonably and unaccountably depressed, seemed to have lost her love for her children and her home. Suffered with gas in her stomach. Was taking a prescription containing iron, arsenic, and quinine. She had been complain-

ing of above symptoms only for a few weeks. On examination I told her that she was not anæmic but the reverse, and had a congested stomach and liver, and asked her if she was accustomed to drink water. Her reply was: "Very little, for I am seldom thirsty." An examination of blood was necessary both to convince her that she was not anæmic, and also that she needed to drink water. Blood examination showed, hæmoglobin, one hundred and eighteen per cent.; red corpuscles, 6,440,000 to c.mm. Treatment: Moderate doses of nux vomica and hydrastis, six to eight glasses of water daily, and a diet largely of vegetables and grain foods. On the 27th of the same month blood examination showed, hæmoglobin, one hundred and five per cent; red corpuscles, 5,480,000 c.mm.

With the change in blood had come a change in her digestion and a removal of sufficient of her bad feelings, mental and otherwise, so that she went home and again took up the care of her family. Keeping up the water-drinking and diet at home.

Case II.—February 20, 1893, Mrs. P——, aged forty-eight, rheumatic gout, subacute, six months' standing, had not menstruated in two years. Inquiry showed chronic constipation. She rarely ever drank water, except in the tea or coffee she took at her meals. Had been a nervous invalid previous to her present illness. I could not induce her to drink water until I had shown her the concentrated state of her blood by examination. She always insisted that it gave her a load in her stomach.

February 20th.—Hæmoglobin, one hundred and twenty per cent.; red corpuscles, 7,080,000 c.mm. Treatment: Diet, meat sparingly; vegetables, fruit, and grain foods freely, except sugar and white bread. Water, 2½ to 3 quarts per day. Medicine: Phosphate soda, 30 grains before each meal in a glass of hot water.

April 5th.—Blood examination: Hæmoglobin, one hundred and ten per cent.; red corpuscles, 5,020,000 c.mm. Treatment continued.

June 2d.—Hæmoglobin, one hundred per cent.; red corpuscles, 4,120,000 c.mm. During the above time her constipation was cured. Her arthritis stopped attacking new joints, and the inflammation subsided in the ones already diseased. The disease has remained checked, although several of the joints in her hand are still, and will probably remain, stiff.

Case III.—February 25, 1893, Mrs. J. P——, aged forty-four, plethoric habit, suffered from acid stomach and had repeatedly passed biliary calculi. The last attack of the kind occurring after she came under my care. Had almost constant pain and feeling of pressure in head and back of neck.

February 25th.—Blood examination: Hæmoglobin, one hundred and eighteen per cent.; red corpuscles, 6,800,000 c.mm. Treatment: Diet, such as to exclude concentrated starchy foods and sugar, and limiting meat to one meal a day. Water, 2½ to 3 quarts per day. Medicine: Phosphate of soda, 30 grains, in a glass of hot water before each meal. Treatment continued till June 6th, when blood examination showed, hæmoglobin, one hundred and eight per cent; red corpuscles, 6,300,000 c.mm. This was a chronic case, so that improvement was slow, but all the troublesome symptoms were much lessened, and while I have not seen her since June last, I heard from her frequently until last December, during which time she had continued the treatment and had also continued to improve.

The above cases will be sufficient to illustrate what I consider the influence of water on a considerable class of cases, for while I did give medicines, still I think the results were due much more to diet and water than to medicine.

Dentistry and the Postal Service.—The regulations of the British Post-Office require that every unsound tooth shall be taken out of an applicant's head before he can be employed. An unfortunate girl who recently was examined for promotion had fourteen teeth taken out at one sitting.

A COMPARATIVE STUDY BETWEEN THE RESULTS OBTAINED BY EXAMINATION OF THE STOMACH CONTENTS BY MEANS OF A STOMACH-TUBE AND EINHORN'S STOMACH-BUCKET.

By GEORGE S. DICKINSON, M.D.,

ERIE, PA.

The examination of the stomach contents serves the purpose of ascertaining the chemical condition of the gastric juice. As is well known, the main point of examination is to determine the amount of HCl present, or the total acidity, and the presence of the ferments pepsin and rennet. The acidity is, as a whole, formed by the presence of free HCl, the lesser part by acid salts and acid albuminates, except in grave pathological conditions, when we find the acidity to consist of organic acids, the principal one being lactic acid.

The chemical examination of the stomach contents is best made either one hour after Ewald's test breakfast, or three or four hours after Leube's test dinner. The test breakfast consists of a roll without butter, and a cup of weak tea without sugar or milk.

The test dinner consists of thirteen fluid ounces of either flour or barley soup, two ounces of scraped beef, one and two-thirds ounce of wheat bread.

Einhorn and Ewald prefer the test breakfast for correct examination. The examination is best performed as follows: First, test with litmus paper, to ascertain if the contents be acid, alkaline, or neutral; the next step is to test with congo paper, to ascertain the presence of free acids. The Uffelmann's reaction or test serves to show the presence of lactic acid. This test is performed as follows: Take about two drachms of a two per cent. phenol solution in a test tube, then add a drop of liq. ferri sesquichlorati. If lactic acid be present in any quantity the solution will turn canary yellow.

To determine the total acidity, take five c.c. of the obtained gastric contents which has been filtered, and add a drop of phenolphthalein; after this is done add as much of a one-tenth standard solution of sodium hydrate until the filtrate begins to turn red, then multiply the number of c.c. of the sodic solution used by twenty, which gives us the total acidity. After having ascertained the total acidity, the next step is to determine the amount of free HCl present. This is done by adding a drop of congo red to five c.c. of the filtrate, then by adding the one-tenth sodic solution until the filtrate begins to turn reddish-brown.

The quantity of the reagent used, multiplied the same as in ascertaining the total acidity, gives the amount of free HCl present. Having found the quantity of free HCl present, we look for the ferments, the most important one of which is pepsin; but as the presence of one ferment shows the presence of the other, there is hardly any necessity of making other than the test for rennet.

This test is performed as follows: Take about two drachms of milk and add a few drops of gastric juice, then place in warm water for ten to fifteen minutes. If rennet is present the milk will become curdled, and will not flow out of the glass.

Having now described the usual method of examining the stomach contents obtained by means of the tube, I shall briefly describe Einhorn's bucket and the method of its use, and append hereto a table of the results of the examination made of the contents of the stomach of the same individuals and at the same time, firstly by the stomach-tube, and secondly by Einhorn's bucket, showing comparative results obtained from both methods.

As is well known, the insertion of the tube, although the procedure is not a difficult one, is, notwithstanding, very disagreeable to some people, and sometimes its use is not allowable, especially in cases where there is a suspicion of ulcer. Einhorn[1] devised the stomach-bucket, to be used instead of the tube in cases of very nervous people, and also where the tube would be otherwise

[1] Max Einhorn: MEDICAL RECORD, July 19, 1890.

objectionable. The bucket is of solid silver, about three-fourths of an inch in length, shaped like an empty capsule, and has a little rod at the top where the silk is fastened. On one side is a wedge-shaped opening and on the other is a small hole about the size of a pin-head, which acts as a vent. The bucket will hold about half a drachm. The method of introduction is as follows: A silk thread is fastened to the arch of the bucket and a knot is made at a distance of sixteen inches from the attachment; then, in order to obtain a sample of the stomach contents, the patient is asked to open his mouth widely and the bucket is placed on the root of the tongue, almost in the pharynx, when the patient should be told to swallow. The vessel after a short time, one or two minutes, enters the stomach. As soon as the knot of the thread is at the lips, the bucket is in the stomach, for the distance from the teeth to the cardiac orifice is usually sixteen inches. The bucket is permitted to remain there for about five minutes and then withdrawn. During the withdrawal of the apparatus a resistance is usually felt at the introitus œsophagi. To overcome this difficulty, when the apparatus is at that narrow point the patient should swallow. By the act of swallowing the larynx is pushed forward and upward, and thus the passage is free and the bucket can be withdrawn easily. If the stomach is not empty, the bucket returns filled, and the amount is sufficient for making various important tests. In people suffering from an abundant secretion of the mucous membranes the bucket might become filled with mucus before entering the stomach, and then, in emptying the vessel, one would find clear mucus instead of chyme. In such cases it is necessary to make the trial again and to cover the opening with a thin gelatinous capsule, which keeps away the mucus from the vessel on its way to the stomach; there the capsule is quickly dissolved and the stomach contents can now enter the bucket. On its return from the stomach, the bucket being filled, the mucus cannot, to any extent, enter into it. As with the tube, the best time to use the bucket is one hour after Ewald's test breakfast. The bucket should always be dipped into warm water before using, in order to wet the inside so that the stomach contents may readily enter it. After using the bucket, as well as any other part of stomach apparatus, it should be washed in an antiseptic solution.

The method of examination of stomach contents obtained by means of the bucket is, according to Einhorn, as follows: The contents are emptied on a small porcelain dish, then, by means of litmus paper, ascertain whether the contents be acid or not; if acid it will turn the paper red. With congo paper, whether there are free acids or only acid salts, the presence of free acids turns the congo paper blue, otherwise the paper remains unchanged. If there are free acids the test should be made to ascertain the presence of HCl. For this purpose take one drop of the contents, and one drop of Guenzburg's solution, and mix them thoroughly in a porcelain dish, which is then heated over an alcohol lamp until the fluid evaporates; a cherry-red color appears in the same spot if HCl be present, even in a very small amount. Having ascertained the presence of HCl, the acidity can be approximately determined by gradually diluting one drop of the contents with water, until the above-mentioned Guenzburg's reaction for HCl begins to disappear. Normally the stomach contents can be diluted from eight to ten times, and yet obtain Guenzburg's reaction. In this way cases where we are able to dilute five times, or even less, must be considered as cases of subacidity, and cases where we are able to dilute more than twelve times as cases of hyperacidity. In cases where no acidity whatever is found, we have to deal with anacidity.

The test for rennet is done as previously described.

Take much care in introducing the bucket, and you will not meet with any failures. The silk should be good and strong, and must be changed very often. It is best to speak to your patient while the bucket is being swallowed, or to make him laugh, in order to assist the bucket into the stomach. We very seldom meet with persons who cannot swallow the bucket. The bucket has been used by many in this country and in Europe; Stockton, of Buffalo, Fenwick, of London, Stewart, of Philadelphia, and others. Tweedy (in the *Dublin Medical Journal of Medical Science* of February, 1894) reports cases in which he has used it advantageously.

While studying under Dr. Einhorn, of New York, I made the following examination to compare the two methods:

Number.	Name.	Date.	Stomach Tube.				Stomach Bucket.			Remarks.
			Time when examined.	HCl.	Acidity.	Free HCl.	Rennet.	HCl.	How many times diluted.	Rennet.	
1	W. M.	January 3, 1894	One hour after breakfast	+	100	90	Present.	+	18+	Present.	A very nervous patient.
2	F. G.	February 25, 1894	One hour after breakfast	+	96	86	Present.	+	20+	Present.	
3	M. S.	January 5, 1894	One hour after breakfast	+	100	80	Present.	+	18+	Present.	
4	M. K.	February 11, 1894	One hour after breakfast	+	94	82	Present	+	15+	Present.	
5	A. H.	January 5, 1894	One hour after breakfast	+	90	75	Present.	+	22+	Present.	
6	F. G.	February 15, 1894	One hour after breakfast	+	80	70	Present.	+	6+	Present.	
7	W. G.	February 15, 1894	One hour after breakfast	+	76	60	Present.	+	8+	Present.	
8	W. S.	February 4, 1894	20 minutes after breakfast	+	76	56	Present.	+	15+	Present.	One hour after meal stomach was empty. A case of hyperkinesis.
9	M. B.	February 8, 1894	One hour after breakfast	+	68	56	Present.	+	8+	Present.	
10	S. S.	January 2, 1894	One hour after breakfast	+	54	40	Present.	+	7+	Present.	
11	R. F.	January 2, 1894	One hour after breakfast	+	40	20	Present.	0	0	0	Very little contents with tube.
12	W. F.	March 3, 1894	1½ hour after breakfast	+	.....	.....	Present.	+	12+	Present.	Too small amount of stomach contents with tube to make examination.
13	S. L.	March 4, 1894	Two hours after breakfast	.....	.....	.....	.....	+	5+	Present.	Too little to make acidimetric test.

As a whole, from this table we can see that the method of ascertaining the acidity by means of dilution of stomach contents obtained by Einhorn's bucket corresponds closely with the results obtained by the acidimetric system, although there are sometimes exceptions (as for instance Case 6). The stomach-bucket and the simple method of testing the gastric juice as described above deserve high recommendations.

428 East Sixth Street, Erie, Pa.

The Consumption of Beer.—According to some statistics compiled in Vienna there was a vast consumption of beer in the world during the year 1893, amounting to over 4,500,000,000 gallons. Germany heads the list with 1,202,132,074 gallons, an increase of 34,000,000 over 1892, the consumption being thirty-three gallons per head, ranging from sixty-two gallons in Bavaria to twelve gallons in Lothringen; Great Britain second, 1,165,752,000 gallons, or thirty per head; America, including the whole of the western hemisphere, is third, with more than 1,000,000,000 gallons, or sixteen per head. More than 7,270,000 tons of malt and 82,000 tons of hops were used in the manufacture of the beer for the world.

The American Medical Association.—The State of Virginia with over 2,800 physicians has 38 members in the American Medical Association; North Carolina with 1,600 physicians has 17 members; Texas gives from her 3,700 doctors 71 members; Mississippi, 21; Kentucky, 87; Maryland, 49; Louisiana, 29; South Carolina, 18.—*The Southern Clinic.*

POINTS TO BE REMEMBERED IN THE PRACTICE OF ANTISEPTIC SURGERY.

By EDWARD PENDLETON, M.D.,

OWENSBORO', KY.

1. Remember to boil instruments for thirty minutes before an operation, when time permits.

2. Remember to use clean, filtered, boiled water in all operations.

3. Remember to immerse instruments only in a carbolic or Listerine solution; the mercurial solution blackens the instruments and ruins the edges.

4. Remember not to dip soiled cotton in an antiseptic solution, after it has been about the wound; use a new piece.

5. Remember not to touch a sponge or instrument that has fallen upon the floor; it might get back into the vicinity of the wound again.

6. Remember to put the suture or ligature back into the antiseptic solution when it has touched anything that is not aseptic.

7. Remember that the surgeon and his assistants are to scrub, cleanse, and disinfect their hands and forearms before an operation.

8. Remember that the vicinity of the wound is to be shaved, scrubbed, cleansed, and disinfected.

9. Remember not to use a rubber bandage in forcing blood out of a part, like a gangrenous or tuberculous limb, but simply apply constrictor above the point of disease.

10. Remember to use no antiseptic upon the peritoneum or any of the viscera; if the operation was aseptic, antiseptics could do no good; if the operation was not aseptic, antiseptics could not make it aseptic.

11. Remember to try always to arrest a bleeding artery by torsion, only use the ligature as a *dernier ressort*.

12. Remember that venous and capillary hemorrhage can be arrested by the application of a hot mercurial lotion to the bleeding surface.

13. Remember to use cocaine in amputating toes, fingers, etc., and in circumcision.

14. Never give ether when albumin is present in the urine, or when there is any pulmonary trouble.

15. Remember always to open an abscess by a free incision, wash out abscess cavity with a carbolic solution (1 to 10), insert a perforated drainage tube in the deepest part, and apply a moist antiseptic dressing.

16. Remember to wash gun- and pistol-shot wounds in a mercurial lotion (1 to 3,000), and pack the wound with iodoform gauze, so that it can heal from the bottom.

17. Remember to use black pins in surgical dressings; they will not rust and can be more readily seen.

18. Remember to let all rubber goods, such as catheters, rubber bandages, fountain syringes, rubber sheets, rubber bags, rubber aprons, dry before they are put away.

19. Remember to boil all instruments that have been used about a person with cancer, syphilis, or tuberculosis, in a carbolic solution (1 to 30).

20. Remember always to cleanse a hypodermic needle, and run a piece of wire through it after it has been used.

21. Remember to thoroughly wash, cleanse, and dry all instruments after each operation.

22. Remember to use gauze sponges, which can be thrown away after they have been used.

23. Remember to use silk in suturing parts about the face.

24. It is not necessary to have a caseful of instruments to perform an operation, only a few are at times necessary.

25. Remember always to cleanse and disinfect a catheter after it has been used; the most common source of infection of the bladder is by an unclean catheter.

26. Remember to use moist antiseptic dressings in all septic cases, such as abscesses, bone felons, lymphadenitis, etc., or where primary union is not expected.

27. Remember to remove silk sutures on the third or fourth day.

28. Remember that the edges of a wound have to be in exact apposition, and no turning under is to be present if union by first intention is desired.

29. Remember to dust iodoform over the line of sutures covered by iodoform gauze, cotton, tissue, and a rubber bandage.

30. Remember to use the fingers in anointing instruments instead of putting the instruments which are soiled into the ointment.

529 Locust Street.

EXCISION OF HEAD AND FOUR INCHES OF SHAFT OF HUMERUS, WITH CASE.[1]

By W. E. GUTHRIE, M.D.,

BLOOMINGTON, ILL.

It is not my purpose to enter into an historical discussion of resection of the upper end of the humerus, nor to describe the minutiæ of the operation except in so far as may be necessary to show the feasibility of the operation, and the possibility of procuring return of function in the injured member.

Reports of investigators prove that this resection is no more dangerous than amputation at the shoulder-joint, and, if successful, the result amply compensates for the increased trouble of the excision. If done for old dislocation of shoulder with anchylosis, or for disease of the head of the humerus where there is not extensive destruction of tissue, the periosteum can be saved, and thus much of the bone be restored. Experience, however, has generally shown that the best result to be expected in most cases is a loose flail-like joint. Gunshot wounds, which have been the most common cause for this operation, usually produce so much destruction of tissue as to make the salvation of periosteum a difficult matter. Especially is this true when the wound is inflicted by a shot gun at close range. The shot strike the bone, and then, scattering, carry destruction into the tissues around the joint. If the amount of bone excised be large, and a generous amount of periosteum be unsaved, the arm may be immobilized, using the body for a splint, and a flail joint expected, or the end of the humerus may be placed in the glenoid fossa, and anchylosis almost certainly awaited.

From all the reports of this operation which I have been able to collect and study, it appears that such a favorable result as I have had the good fortune to obtain in the case to be presented to you to day is remarkably rare.

October 22, 1893, James H——, eighteen years of age, was near Towanda, Ill, hunting squirrels with a shotgun loaded with small shot. Being somewhat wearied by his tramping he sat down on a rail fence to rest and refresh himself, placing the stock of his gun on the rail below and holding the barrel loose in his arms before him. By some means the butt of the gun slipped from its resting place and fell, striking the hammer on the rail and discharging the piece. The entire charge (shot, burnt powder, and wads), together with shreds of clothing, tore through the anterior border of the axillary space, severing in its course the pectoralis major, long head of the biceps, the anterior fibres of the deltoid, part of the short head of the biceps, the infraspinatus and teres minor muscles, crushing the head of the humerus and shattering the upper portion of its shaft, and destroying the insertion of the subscapularis and supraspinatus muscles. After shattering the bone the shot scattered in every direction through the enveloping muscles. The opening through the skin was at least an inch and a half in diameter, its margins ragged and bruised.

He was soon seen by Dr. W. H. Reedy, of Towanda, who picked out some pieces of bone, and had him removed to his home, about six miles away, and advised that I be called.

It was several hours after the accident when I reached his bedside. He had partially reacted from the shock;

[1] Read before the Illinois State Medical Society, May 16, 1894.

but as he had not sufficiently reacted for operation, and there was very little hemorrhage, and the lights at our disposal were poor, the wound was cleaned and temporarily dressed, awaiting the morrow for operative attention. Sunday morning, October 23d, assisted by Drs. Reedy and Anderson, the patient was anæsthetized with A.C.E., and the axillary artery being in good condition, resection of the head and upper four inches of the shaft of the humerus was done. The wound was enlarged upward to a point even with the top of the head of the humerus, and through this opening the pieces of bone were removed one by one, care being taken to strip the periosteum from each piece before removal, and a portion of bone was scraped off with each muscular insertion into the broken bone. The removal of the periosteum, tendon, and muscle was surprisingly easy by reason of the chisel-edged raspatory used. The fragments being removed, the point of the shaft was pushed up through the wound by an assistant and sawed off even with a chain-saw. The most time was consumed and the greatest difficulty encountered in cleaning out the shot, burnt powder, scraps of clothing, and dead muscular tissue. He had been under the anæsthetic two hours and a quarter before I was satisfied that I had made the wound as clean as possible. The cavity was then carefully washed out with a sublimate solution, and about two ounces of a ten per cent. solution of iodoform in ether poured into the depths of the wound, and the latter thoroughly packed with iodoform gauze.

Ordinarily I believe it good practice to raise the arm before dressing until the end of the severed humerus rests in the glenoid fossa. In this case I did not follow this course, fearing that the great destruction of tissue in the neighborhood of the joint would later infect the open end of the bone and cause suppuration and perhaps sepsis. So the axilla was thoroughly padded, the arm left at the side in a natural position, the forearm placed across the chest, and the whole immobilized by numerous strips of adhesive plaster. There was no subsequent hemorrhage, no pain, no elevation of temperature above one hundred degrees. Through the gauze there was a copious serous oozing. Two days later the gauze was removed without disturbing the arm, two drainage-tubes were inserted, one downward to the end of the humerus and one backward into the depths of the wound, and the portion of the opening made by my knife was closed by suture. As stated before, there was no pain and no inflammation. The only complication was vomiting and pyrosis for several days. Otherwise he made an uninterrupted recovery. Drainage by means of rubber tubes, and later silkworm gut, was kept up for several months, a stray shot coming away occasionally. For several weeks it has been entirely healed. It is now a little more than six months since the operation. As you see, there is no shortening of the arm. Nature has replaced the bone removed by another growth, the upper end of which you can feel rests in the glenoid fossa; the axilla is of full capacity. When I push upward on his elbow you see I raise the whole shoulder, thus proving the bone has been entirely restored. This young man is a farmer, and prides himself that he has "made a hand" on the farm this spring. He milks the cows with both hands, feeds himself with the left hand (the injured side), and, although the range of mobility of the arm is not large, it is gradually increasing with restored muscular power, and, all things considered, the result is very satisfactory. I show you also the portion of bone removed by me. I have had the pieces placed in their natural relation to each other and glued together. A portion of the head you see is missing, the portion, I suppose, that was removed at the scene of the accident.

As near as I can find, this case is unique on account of the amount of bone restored and the remarkable restoration of function in so short a time.

The Contagiousness of Tuberculosis is denied by Dr. Sprae, of Norristown, Pa.

Progress of Medical Science.

Care of the Mouth in Sick Persons.—Rosenbach says that in many illnesses there is almost sure to be secondary trouble in the mouth if preventive measures be not taken (*The British Medical Journal*). A warning sign is dryness and redness of the tongue and mucous membrane of the mouth, with difficulty in swallowing; further signs are an evil odor from the mouth, coated tongue and gums, bleeding of the gums, etc. Just as special care of the mouth is required in patients with carious teeth, smokers, and chewers of tobacco, so it is also in the case of unconscious or paralyzed persons; patients with fever or suffering from chronic digestive complaints; those taking medicines, such as mercury or iodides, or who, on account of general weakness, have to take strong alcoholic drinks; but, perhaps, the most important class of those in whom special care of the mouth must be taken are patients with fever. Parasites are always present in the mouth, but it is only when the tissues are weakened that they undergo invasion by these parasites, which become then really pathogenic. There is nothing which one can do for sick persons which is unimportant, and by neglect in the care of the mouth convalescence may be retarded. Rosenbach concludes with the following rules: (1) Patients with good digestive powers, free from fever, and with no loss of consciousness require no more than the ordinary care of the mouth. (2) In children and very old patients the less solid food taken the greater should be the care with the mouth. They should rinse the mouth out several times a day with lukewarm water containing a little common salt, tincture of myrrh, or eau de-Cologne added to stimulate secretion. When there is a tendency to bleeding of the gums, or when the teeth are bad, a pinch of powdered boric acid may be twice daily rubbed in between the lips and gums. Patients with false teeth should remove their false teeth when, owing to loss of appetite or chronic gastric disturbance, they cannot take solid food. (3) In patients with partial loss of consciousness the mouth should be examined several times a day for small sores, such as may arise from the pressure of the teeth on the lips, etc. Such sores should be powdered with a little boric acid or chlorate of potash, and the cracks at the corners of the lips heal quickly if dried with a clean towel and treated with boric acid or vaseline. The mucous membrane may be stimulated by wiping the tongue and mouth, and pressing on the tongue with a moist towel every two or three hours; if necessary, the hinder part of the tongue should be cleaned with a wad of cotton-wool fastened to a stem. If the patient sleep with the mouth open the air in the room must be kept moist; a moistened layer of muslin laid on the mouth may be of some service. (4) Patients with fever should have something to drink—cold water or weak lemonade—at least every hour; one must not wait until the patient asks for drink. Besides preventing dryness, the fluid maintains the activity of the glands and the whole function of the mucous membrane. Many patients are prevented from drinking by a painful, dry, and cracked condition of the lips, and therefore all feverish patients should, from the commencement of their illness, have their lips rubbed several times a day with vaseline or fat. In protracted cases of fever the mouth may also be swabbed out with oil, fat, or greatly diluted glycerine.

Total Abstainers in the Indian Army.—The Army Temperance Society of the British army in India has grown from 13,000 members in 1890 to over 22,000 members to-day. Out of 1,100 regimental courts-martial for 1893, only 39 sat to try members of the Temperance Association, and of 2,680 courts-martial of all classes for that year, only 73 concerned temperance men.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, September 15, 1894.

AS OTHERS SEE US.

LAST year medical men and matters on this side of the Atlantic were observed and freely commented upon by that veteran medical journalist, Mr. Ernest Hart. We have again been subjected to observation and comment by one of our transatlantic brethren—a German. A book recently published by Dr. Placzek,[1] a Berlin neurologist and litterateur, pictures the medical profession in this country with the pen of a discriminating observer. The surprise and pleasure which the revelations of his journey produced upon the author are quite naïvely told. A few extracts from the work may enable us to "see ourselves as others see us."

In his introduction, the author expresses surprise and admiration of the spirit which pervades our eleemosynary institutions. "The European physician, whose vision is narrowed by the diminutive size of his own country, does not conceive that beyond the wild-heaving Atlantic there lies the land of promise, *par excellence*, a land of immeasurable resources, in which the talents of the individual may hew out a career unimpeded by European class distinction." The author believes that the pilgrimages now made to Europe by our physicians will cease; that schools will ere long be created whose disciples, as "thoroughly educated as their European colleagues, will reach out toward the goal of knowledge with the same zeal, the same ability, and the same thoroughness." With the penetration of a skilled observer, Dr. Placzek, in describing our hospital system, emphasizes the fact that we do not rely upon the state for aid as they do in Germany, but "the cruel help yourself," which rules in all branches, permeates also, strange as it may seem, all purely humane efforts." Nor is he slow to recognize that, "while our institutions built and maintained by the state are often sadly defective, most of those initiated by private enterprise are models of astonishing completeness." He acknowledges that the European errs in regarding the American as a "dollar hunter" devoid of all sentiment, citing as evidence the fact that a vast stream of money flows constantly into the coffers of our hospitals, much of which is given "in memory of a wife, son, or daughter," as recorded pathetically on tablets over some of the beds. The shadowy side of the picture is brought out in his reference to the fact that, despite their great wealth, these corporations accept the services of medical men without compensation, and that the lay directors entirely control the affairs of the hospital. He especially condemns the authority of the superintendent, which he erroneously regards as supreme in all our hospitals. The comfort and elegance of our hospitals are brought into striking contrast with those of Germany, and this is emphasized by well executed illustrations. Our ambulance system and our training-schools for nursing elicit the author's highest encomiums, and are held up as examples worthy of imitation. He is struck by the extravagance in the arrangement of our dispensaries (which he calls the children of sorrow of medical practice); he justly condemns the reckless disregard of the interests of the profession displayed in their administration. Under the caption of "Therapeutic Tendencies," the author alludes to the contrast between German therapeutic nihilism and the implicit faith in drugs of the average American, which he attributes to imperfect education. He assigns the latter as a cause of the glaring disregard of the newer therapeutic methods, citing rational hydrotherapy as an example. "The process of development through which this therapeutic method is passing, in order to conquer the position to which it is entitled, will always be noteworthy in the history of American medicine. To the zeal of a New York physician, who is conducting the battle for the introduction of this powerful agent with unflagging industry, the credit will be due if the opposition to this method, which has long ago attained recognition in Europe, shall be overcome." He finds electro-diagnosis and therapeutics as little "the general property of the profession here as it is in Europe, and he regrets to note that massage is entirely in the hands of laymen." Our insane asylums receive extensive notice, and many illustrations are furnished to emphasize their elegance and comfort. Our quarantine system is regarded as too exacting; its excessive demands being illustrated by the detention of the Normannia last summer. "The American's fear of contagion is well known; he expects protection from the quarantine officer;" thus Dr. Jenkins's rigorous measures are condoned, the European idea of the American doctor, that he is a sort of inferior being, a practical merchant, is regarded as a great error by the author. "Reality develops quite a different picture," says he. "In vain do we look over there for the large and showy signs announcing the doctor to be "a practical physician, surgeon, and accoucheur, or specialist for larynx, throat, or nose." Not even the well-known "free to the poor" is found anywhere. Nothing of all this, only a small sign in the inside of a window stating the doctor's name and office hours." An extract from the Code of Ethics concludes this interesting chapter, with the statement that our "codex of morals is far more strict than that customary in Germany."

Our educational facilities are fairly well presented, they are concluded with a just criticism upon the following defects: 1. Imperfect preparatory education. 2. Excessive theoretical instruction. 3. Insufficient clinical teaching. 4. Insufficient practical activity. 5. Brevity of course of study.

Our sanitary and hygienic affairs are largely, and upon the whole favorably, commented upon.

Taking the book as a whole, we have reason to be proud of the impression made upon a representative German colleague, whose clearness of perception is equalled by the fairness of his criticisms.

SOME EXPERIENCES OF THE DOCTOR'S WIFE.

The doctor's wife has had many kind and sympathetic things said about herself and her lot. A whole book has even been written regarding her trials, her duties, and her pleasures. The theme is a fertile one; and a Brooklyn doctor's wife has recently and happily enriched it through the columns of the New York *Times*. Some of her comments will no doubt wake responsive notes in the minds of the many doctors' wives who read the Medical Record.

"The apologies of the people who do not employ my husband as a physician," says the Brooklyn lady, "are the funniest things yet. It is an extremely delicate thing to receive these apologies in a delicate manner. You really do not know what to do. I think sometimes a doctor's wife who says just the right thing must be inspired. You have to say the very best things you can for the physicians they employ. This is a big world and a hard world, and it is always best to say all the good you can about every one. People are apt to ask your advice, too, about which you consider the best, the regular or the homœopathic school of medicine, but although they ask the question they are very likely to feel terribly grieved if you say anything against either school."

It is a standing grievance with some wives that they have to be called "Mrs. Doctor."

"How many times," she says, "I hear that expression. People do not seem to realize that you got the 'Mrs.' alone and not by degrees, but by just a few words. The certificate one gets at that time has nothing to do with degrees or 'Mrs. Doctor.' I suppose it is because of 'Mrs. Doctor' that there is hardly anything I have not been asked to do when the doctor was out, from setting a broken arm to pulling a tooth. And the people will not see why I cannot do it.

"One man wanted a prescription. He said he knew exactly how the signs looked on paper, if I would only make them. The druggist would not give him the medicine without the paper. Another man could give an exact description of the bottle some medicine was taken from if I would only get it for him."

The Brooklyn doctor's wife would evidently be glad to join the "Society for the Abolition of the Doctor's Title," for she says:

"The life in a house behind a brass sign seems to me different from other lives. There you are ticketed. When you stand in the window you are not a private woman in a private house. You are Mrs. Doctor So-and-So to every one who happens to look your way.

"You are never sure of an evening, and you may sit waiting with gloves on until long past calling time, and the doctor won't come after all. To be a doctor's wife means to go to dinner-parties alone, with your escort arriving perhaps with the second or third course. It is a dual life, with the doctor's wife spreading herself like thin varnish over it all. Then, and it is not the least of all, the doctor's wife has to look after the family carving."

From all of which we should infer that if a young woman were to take any advice about marrying a doctor it should be *Punch's* general admonition: "Don't." Fortunately advice is not asked as to matrimony by the woman of to-day.

News of the Week.

Free Alcohol.—The result of the unintentional placing by the new tariff bill of alcohol used in the arts on the free list will, it is said, reduce the price of tinctures, perfumery, and spirit varnish from fifty to sixty per cent.

Milk from Tuberculous Cows.—In a recently issued Agricultural Department report, on tuberculosis in cattle, by Theobald Smith, chief of the animal pathology department, it is stated that investigations undertaken by the department show that the milk of tuberculous animals is not so infrequently infected as supposed. Milk of animals in the earliest stages of the disease and with perfect udders, does not contain tubercle bacilli. Only those showing signs of labored breath and emaciation should be gravely suspected, and their milk excluded at once from sale.

A Statue to Claude Bernard will be unveiled at Lyons on October 26th. The French Academy has appointed MM. J. Bertrand and Brunetière to represent it on the occasion. The Académie des Sciences will be represented by MM. Chauveau and Bouchard. As the first French Congress of Internal Medicine will be in session in Lyons at the time, it is expected that the ceremony will be exceptionally brilliant.

The American Academy of Medicine.—At the annual meeting of the American Academy of Medicine, held at Jefferson, N. H., the following officers were elected: *President*, J. McFadden Gaston, M.D., of Atlanta; *Vice-Presidents*, Rufus P. Lincoln, M.D., of New York; William T. Smith, M.D., of Hanover; Helen C. Putnam, M.D., of Providence; Victor C. Vaughan, M.D., of Ann Arbor; *Secretary and Treasurer*, Charles McIntyre, M.D., of Easton, Pa.; *Assistant Secretary*, Edgar M. Green, M.D., of Easton, Pa.; *Member of Council*, Charles C. Bombaugh, M.D., of Baltimore. The next meeting will be held in Baltimore, May 4, 1895.

Deaths from Chloroform.—From August 10th to September 1st, there were three deaths from chloroform anæsthesia in London hospitals.

A New Pulmonary Disease—"Pulmonea."—Dr. J. W. Power, of Caylloma, Peru, says in *The Lancet* that pulmonea is a name given by the native Peruvian miners to an affection of the chest simulating acute pneumonia in the consolidation stage, and might easily be mistaken for it. In these altitudes (15,600 feet) the sudden daily extremes of temperature (75° to 38° F. average) natural to the climate, and the inhalation of the irritating dust of the dry stamps of the mills and smelting fumes, make cases of pulmonea of daily occurrence. Miners with pulmonea will present themselves complaining of inability to work, of a dull pain under the heart and between the shoulders, of cough and sometimes blood spitting, and distress of breathing. Inspection of the chest shows increased and quickened breathing. There is increased vocal fremitus, with marked dulness on percussion, and increased resonance over both lungs at the back of the chest—under, as it were, the seat of pain. Sometimes roughened breathing can be heard, but not tubular. However, there are no febrile symptoms, and the absence of these and the tubular breathing are the only differences between the two affections. I have made ne-

cropsie of two men whom I had previously treated for pulmonea, who had died from the effects of mining accidents, and in both cases I found the glands in the posterior mediastinum greatly enlarged, inflamed, and thickened, forming a compact mass in a situation which would just correspond to the seat of pain, and I have no doubt that these glands were the cause of the symptoms and physical signs which I have described. Their condition was probably caused by the irritating matter continually inhaled by the men. With regard to treatment, painting the back with iodine, and syrup of the iodide of iron given internally, with a few days in the fresh air, will remove all the unpleasant symptoms, but not the physical signs.

A New Gas.—The various medical societies, academies, sections, etc., which are about to begin the fall and winter season will be interested in learning that Lord Raleigh has discovered a new kind of gas, resembling nitrogen.

Pasteur's Vaccination.—The authorities of Lower Austria have decided that a station for vaccinating against rabies shall be established in the neighborhood of Vienna.

St. Louis has an Electric Ambulance.—The St. Louis authorities have adopted a plan of conveying patients from the Dispensary to the city hospital by means of an electric railway ambulance. A street car, with electric motor attachments, has been fitted up as an ambulance, and the system has been successfully put to work. It is intended to run the car to all parts of the city in response to ambulance calls. The car will be permitted to make an average speed of twelve miles an hour.

The Tri-State Medical Society, with membership from Illinois, Iowa, and Missouri, will meet in Jacksonville, Ill., October 2 and 3, 1894. Valuable papers are promised from leading members of the profession of Chicago, St. Louis, Kansas City, Indianapolis, Keokuk, Springfield and other places. A large and profitable meeting is anticipated.

The Cholera.—The epidemic in Russia has assumed large proportions again during the past week, or else, as is very probable, the invasion of new districts for several weeks past was kept secret by the authorities until the number of cases became so great that further concealment was impossible. During the week ending September 8th, 6,376 new cases and 3,192 deaths were reported in Russia proper, and the weekly average of new cases in Russian Poland is 5,000, with a mortality of about fifty per cent. The disease is very prevalent in Nijni-Novgorod, where the annual fair is now being held. In Galicia and Bukowina, during the three days ending September 9th, there were 533 new cases and 304 deaths. Since the beginning of the epidemic there have been 6,958 cases of cholera and over 3,000 deaths in these provinces. The weekly average of new cases reported in Germany is about 50. It is believed that the Rhine is infected, as cases have occurred on the Rhine steamers. The disease is undoubtedly epidemic in Marseilles, although the authorities persist in their denials that cholera is present there. Most of the Mediterranean ports have established quarantine against that city. Other towns in France in which one or more cases of the disease have occurred are Paris, Bordeaux, Lassay, Rheims, Reuil, and Mancel-sur-Scille. An increase in the number of cases is also reported from Belgium, eleven deaths having occurred in Liége on September 5th, and new cases are constantly being discovered in towns on the Meuse and Sambre rivers, and also in places along the Maas, which is the continuation of the Meuse in Holland. A Bavarian immigrant died in Cumberland, Md., a few days ago with symptoms pointing to cholera, but an investigation by the Marine Hospital authorities has shown that the case was not one of Asiatic cholera.

Failure of Haffkine's Inoculations.—A dispatch to the London *Times* from Calcutta, dated September 11th, says that during the recent cholera epidemic at Lucknow several soldiers who were inoculated with Dr. Haffkine's virus were attacked, and that the proportion of mortality among them was the same as among ordinary patients. This contradicts the results of the experiments conducted by Drs. Hafikine and Simpson, in Calcutta last June. It was then said that few, if any, of those inoculated were attacked by the disease, or if attacked they promptly recovered.

Dr. William C. Dabney died recently from typhoid fever in Charlottesville, Va. He was graduated from the Medical Department of the University of Virginia in 1868, and at the time of his death was professor of obstetrics and the practice of medicine in that institution.

The International Congress of Hygiene and Dermography, which closed its session in Budapest, on Saturday last, will hold its next meeting in Madrid.

Hong Kong is officially declared to be free from the plague, and the port was opened to commerce on September 10th.

Yellow Fever.—The steamer Samuel Tyzak, which arrived in Baltimore from Havana on August 31st, had four cases of yellow fever on board. One of the men died in the Maryland University Hospital, and another occupied a bed in one of the wards before the nature of his disease was discovered. The bark Alice, also from Havana, is at quarantine at Cape Henry, with three cases of the same disease.

Dr. Noah Sanborn died in Bayonne, on September 6th. He was born in Tamworth, N. H., in 1837, but had been a resident of Bayonne for twenty-two years. He served throughout the Civil War as a surgeon in the Northern Army, and at the time of his death was one of the attending staff of the Bayonne City Hospital.

Signor Crispi, Prime Minister of Italy, is reported to be suffering from a cataract.

The Craig Epileptic Colony.—It is probable, as we learn from authentic sources, that the epileptic colony will not be opened for actual work under two or three years. There is perhaps already some trouble about patronage.

Dr. George Thomas Jackson, of this city, has been appointed foreign Secretary for the United States of the Third International Congress of Dermatology to be held in London, July 31 to August 4, 1895.

Hog Cholera is epidemic in Lyons County, Kan. Over four thousand hogs are said to have already died from the disease, and many breeders have lost their entire stock.

Dr. Charles H. Williamson died on Monday, September 10th, at St. John's Hospital, in Brooklyn, in his sixty-eighth year. He was born in Virginia, and served as a medical officer in the United States Navy for some years preceding the breaking out of the rebellion, when he joined the Confederacy. At the close of the Civil War he served as surgeon in the Pacific Mail Steamship Company.

The Cause of Liverpool's High Death-rate.—Some remarks having been made about the high rate of mortality in Liverpool, the medical officer of health in that city has prepared an explanatory statement, in which he attributes the apparent unhealthiness of the town to the density of the population, there being no rural or semi-rural districts within the municipal area, as there are in other places. While in Liverpool there are 114 houses to the acre, there are only 39.9 in Manchester, 38 in Birmingham, and so on to Huddersfield, which has only 8 to the acre. The death-rate in Liverpool is 23 per 1,000, and in Manchester only 18.2; but taking the township district of Manchester, which, to a certain extent, corresponds to Liverpool, the death rate there is 27 per 1,000, which is greater than that of Liverpool. Turning to London, which, he says, is a very difficult place to say anything about, the average death-rate is 21.3, but in what may be called the urban district of London the rate is 26. The death-rate in Liverpool during the last six months was materially below the average of the last ten years.

English as a Universal Language.—At the session of the American Social Science Association in Saratoga on September 4th, Mr. D. G. Porter, of Waterbury, Conn., read a paper on "English as a Universal Language." He said that in the present century there had been a demand for a universal language. French and the so-called Volapuk had been advocated, and there had been a demand for the revival of the Latin tongue; but the English, the youngest of all the great tongues, seems to be the survivor in the struggle for the supremacy. It was largely owing to the fact, he said, that it was the language which grew from the necessities of the common people, without regard to the rules of orthography or grammar. He traced the formation of the English language from the beginning of the fourteenth century, when the Norman-French that had been forced on Great Britain as the language of its court and legal tribunals was forced to compromise with the Saxon-Danish, which was spoken by the peasantry, so that all classes of people could converse and comprehend each other, and from the necessities that urged that compromise has grown that which requires that the spoken English should be the universal tongue, for of its energy, begotten by the compounding of races, grew the commercial supremacy of England and her colonies, that had encircled the world and carried with it the English speech, until now commerce requires it, and it is even supplanting French as the tongue of diplomacy.

Mr. Porter is evidently not a reader of the MEDICAL RECORD, otherwise he would have had something to say concerning the powerful claims of modern Greek to general acceptance as the universal language of science. Of course, if we believed English had any chance of being adopted as the international means of communication, we should gladly urge its claims; but we fear there is little hope of this. It is commonly said that our tongue is understood and spoken by all educated men in Europe, but anyone who has attended an International Medical Congress on the continent knows how little truth there is in this assertion. Of the three official languages, English is the only one that is tortured beyond all recognition by the official translators, and of all the orators at the general and section meetings, those speaking in English have the smallest and the least attentive audiences.

Obituary.

PROFESSOR HERMANN LUDWIG FERDINAND VON HELMHOLTZ.

BERLIN, GERMANY.

PROFESSOR HELMHOLTZ, the celebrated physicist, died of apoplexy in Berlin on Saturday, September 8th. He was born in Potsdam in 1821, and was educated as a physician, serving his term in the Charité Hospital. He turned his attention almost immediately to the physical sciences, and published his first book on "The Conservatism of Force" when twenty-six years old. The following year he was called to the chair of anatomy in Berlin, and the year after that became Professor of Physiology at Königsberg. Subsequently he filled the same chair at Bonn (1855) and at Heidelberg (1865), and in 1871 was called to the professorship of physical science in Berlin, formerly held by Gustavus Magnus. It was during his stay in Königsberg that he invented the ophthalmoscope and the ophthalmometer. He wrote about one hundred and fifty scientific papers and contributed largely to the physiology of vision and hearing. Among his published works of physiological interest were: "The Nerves of the Invertebrata;" "Heat Generated by Muscular Action;" "Measurements Affecting the Periodical Contractions of Muscles and the Distribution of the Nerves Contained in Them;" "A Method of Measuring Small Intervals of Muscular Action;" a "Manual of Physiological Operations."

He published on optics, "A Sketch of the Construction of the Living Eye," in 1851; "The Theory of Permanent Colors," in 1852; "The Sight of Man," in 1855; and the "Manual of Physiological Optics," in 1856. In 1862 he published his "Theory of the Impressions of Sound," and a little later a work which attracted wide-spread attention, entitled "Sensations of Tone as a Physiological Basis for the Theory of Music."

He loved science for its own sake and looked for his reward in the pleasure occasioned by the search for knowledge rather than in that caused by the possession of knowledge itself. He developed this thought and showed the spirit which had animated his life work in the course of an oration which he pronounced on Gustavus Magnus, his predecessor in the chair of physical science in Berlin. "Knowledge alone," he said, "is not the design and object of men on earth. Although science awakens and cultivates the most subtle forces of the human mind, yet he who studies only to know will not find the true object of his existence in this world. . . . A thorough knowledge of the operation of the natural and mental forces is all that scientists can attempt to acquire. The student must feel himself rewarded by the pleasure found in hailing new discoveries, new victories of human effort and human thought, over opposing material forces. He can find pleasure in the beauty which a well arranged department of knowledge exhibits, in the coherence of relation between its different parts, perceiving how one part grows out of, or is developed by, others, and he must find high enjoyment in the consciousness of having contributed to the growing chapter of general information, in thus assisting to manifest the supremacy of man over the forces and material of nature."

Clinical Department.

LARGE DOSE OF SULPHONAL FOR A CHILD.

By J. SUTCLIFFE HILL, M.D.,

BELLOWS FALLS, VT.

BELIEVING that the presentation of facts as a result of our observation in cases that come under our care is of interest to our professional brethren, and serve as lessons for our guidance in similar cases in future, is my only reason for presenting the following:

On February 24th, at 7 P.M., I was hastily summoned to the bedside of a child, aged eighteen months. I found an eclectic physician (?) present and learned that the child was taken sick on the Tuesday preceding with some form of bowel trouble.

Status præsens: Child apparently unconscious, pupils contracted, breathing shallow, but regular, pulse 120. On questioning the eclectic he informed me that at 9 A.M. he had given 8 grains of sulphonal, and at 11 A.M. 8 grains more, at 1 P.M. 8 grains more, and between 3 and 4 P.M. 10 grains, making in all 34 grains in a little over six hours. As the child was breathing regularly and the pulse was good I deemed it a good case to wait and watch the effect of suphonal in large doses and so stayed with the patient all night.

The parents had promised me full control of the case before I saw the patient. The child slept profoundly over six hours, and as the parents had become quite anxious for their little one, I managed to rouse the baby and gave a few drops of aromatic spirits of ammonia; the child again fell into deep sleep and slept four hours, when I repeated the ammonia. This continued for over twenty-four hours, when the child could be more easily roused and called for nourishment. During this time there had been difficulty in making water. There was one peculiarity that was very apparent when the child was recovering from the effect of the sulphonal, viz., ptosis of both eyes, which continued for four days, and was very marked.

The case ended in complete recovery, no trouble either of stomach or bowels. To me it was a very interesting case as I have never prescribed over 10 grains of sulphonal at one dose in adult cases.

A CASE OF CHOLECYSTENTEROSTOMY WITH THE AID OF THE MURPHY BUTTON—RECOVERY.

By HENRY MOFFAT, M.D.,

ATTENDING SURGEON, ST. JOSEPH'S HOSPITAL, YONKERS, N. Y.

THE following case seems to me to present some features of interest, and I trust will not be inappropriate, now that so much attention is being paid to the surgery of the gall-bladder.

L. S——, a widow, aged thirty nine, a German domestic, was admitted first to the surgical ward of St. Joseph's Hospital on November 19, 1893, suffering from intense biliary colic with a marked distention of the gall-bladder. She was on the verge of collapse, and cholecystotomy was immediately performed by my colleague, Dr. G. N. Banker, who was on duty at that time. He removed eight large and six small stones. The patient made an uninterrupted recovery and was discharged, December 23d, with a biliary fistula, which persisted for about ten days longer, and finally closed spontaneously. She had one slight attack of colic during January, which was easily relieved, and remained well till February 5th, when she was again seized with most violent pain in the same region as before—the tumor reappeared and rapidly increased in size. She was immediately brought back to the hospital and came under my care.

On admission she was again in a partially collapsed condition, slightly jaundiced, vomiting, and suffering intensely, with a rapid and feeble pulse but no elevation of temperature. The gall-bladder, swollen to the size of a large orange, could be easily made out below and to the mesial side of the former incision. In view of her previous history, and believing that it would be extremely difficult to assure myself of the freedom of the common duct in a secondary operation, I determined to perform cholecystenterostomy, using one of Murphy's anastomosis buttons. In this view my colleagues, Drs. Banker, Benedict, and Pyne concurred. The patient was therefore immediately etherized and an incision, about four inches long, was made three-fourths of an inch to the left of the old scar, parallel to and about two inches from the median line, extending from one inch below the free border of the ribs almost to the level of the umbilicus. The thickened and adherent peritoneum was carefully incised and the distended gall-bladder was immediately disclosed, though it was so bound down and covered by old and strong adhesions that only about one square inch of its surface could be cleared for manipulation. The aspirator was used, and about two ounces of slightly bile-tinged serous fluid was drawn out. The presence of a stone could not be detected, but, feeling perfectly assured that the common duct was obstructed, I proceeded with the operation. The only loop of intestine which could be approximated with any degree of safety was the hepatic flexure of the colon. I attempted to drag one or two loops of the ileum to the point, but found that strong adhesive bands prevented, and had I succeeded, would undoubtedly have produced dangerous and probably fatal constriction of the bowel. The male button was therefore placed in the colon in the manner described by Dr. Murphy, and the female button in the gall-bladder. This latter procedure was attended with considerable difficulty, for the following reasons:

1. The adhesions from the previous operations had bound the gall-bladder firmly down at the bottom of the wound.

2. The surface freed from adhesion was so limited that it was found impossible to make the two stitches described by Dr. Murphy on one side of the incision; one, however, proved just as satisfactory in this case.

3. The walls of the gall-bladder were more than one-fourth of an inch in thickness, rendering it difficult to make them slip into the cup of the button when the ligature was pulled taut. The buttons, being then safely in place, were pushed home and a satisfactory approximation of the parts was made without any undue tension on the surrounding tissues. As there had been some unavoidable leakage from the gall bladder, I packed down to the bottom of the cavity a strip of iodoform gauze and closed the rest of the wound with sutures through the abdominal wall and peritoneum.

The patient made an uninterrupted recovery. Her bowels were readily moved on the third day by a dose of magnesium citrate, and on the seventh day a gall-stone about the size of a hickory-nut was passed per rectum. She was allowed to sit up on the eleventh day, and discharged at her own request on the eighteenth day after the operation. The abdominal wound was entirely healed, with the exception of a small superficial granulating surface, which soon cicatrized over; but she had not passed the button. Dr. Banker saw her several times after she left the hospital, and anxiously awaited the appearance of the button. It was not until March 2d, twenty-five days after the operation, that it was finally passed. She was at that time seized with colicky pains over the whole abdominal region, and a dose of castor-oil produced the long-expected button. She has since been in perfect health and attending to her duties.

In reviewing the case the following points might be noted: 1. The comparatively easy accomplishment, with the aid of Murphy's button, of an operation which is acknowledged by all surgeons to be one of the most difficult. To effect a perfect anastomosis between a loop of intestine and a gall-bladder with thickened walls, and bound firmly down in such an inaccessible position, without the aid of any mechanical contrivance, would call for

the highest technical skill and would be attended with the gravest difficulties. From my experience in this case I feel certain that the Murphy button has proved a most valuable assistant.

2. It must, however, be noted that the danger of the button becoming lodged somewhere in the intestinal tract, is not by any means as trivial as Dr. Murphy wished us to understand. In the above case, from the fact that a gall-stone was passed on the seventh day, it must be inferred that the button had at least partially sloughed away; for the stone was too large to pass through the lumen of the button. And yet, in spite of the fact that the colon was used, it took twenty-five days for the button to pass out of the body. There was, however, no obstruction at any time, and the bowels moved every day.

3. The use of the colon, while not desirable, was absolutely required in this case for the reasons given above, and is not without precedent. Treves quotes a case of Mr. Mayo Robson in which the hepatic flexure of the colon was used for the same reason.

4. The effect of the loss of the physiological action of the bile in the small intestine will be worthy of further observation. At present writing, two months after the operation, the patient is in perfect health, has gained in flesh and strength, and her bowels are acting in a perfectly healthy manner.

A SUCCESSFUL PLASTIC OPERATION OF THE FACE.

By J. J. MULLEN, M.D.,

PITTSBURG, PA.

On December 10, 1893, assisted by Drs. H. Atkinson, of Connellsville, Pa., and J. D. Mullen, of Dunbar, Pa., where the operation took place, I performed a plastic operation on the face of a girl, aged twelve, who had her right eye and cheek entirely destroyed by the accidental discharge of a loaded gun in the hands of her brother. She presented a most pitiable appearance; the lower eyelid was firmly adherent in the cicatrix on the face at right angles to its former or normal position. The cicatrix resulting from loss of skin, fascia, muscles, and bones was permeated with powder and lead, extending from the orbital space along the nose down, and included the upper lip, running obliquely over the lower jaw up along the face close to the ear to the outer commissure of the eye. After satisfying myself that the stump remaining from loss of the eye had cicatrized perfectly and no irregular nodule remained, I dissected the lower eyelid out of the scar and threw it over the patient's nose in a pair of catch forceps. I now made a free and clear dissection of the scar from the points described, with the exception of a small portion along the nose and close to the eye, which subsequently answered a good purpose. The dissection of the scar was not attended by much bleeding, although I used a very sharp scalpel. The dissection being completed (which was the least difficult part), an incision from the margin of the dissected wound on the lower jaw, on the ear side of the wound, down on the neck, three inches or more in length and one and a half inch in width, its distal end being freed and the proximal at a point immediately below the ear, turned at right angles, was brought up to within one half-inch of the eye, where it was sutured to a small margin of sound skin. The other flap was secured by going down on the chin and neck, leaving, however, a portion of sound and undisturbed skin, which divided the space from which the flaps were removed; it was also turned at right angles on the lower jaw and its free end secured to the small piece of cicatricial tissue I left on the nose at the time of dissection. Both flaps were now sutured, one along the side of the nose, and the other to a slight margin of sound skin along the ear. The two free edges now in the middle of the wound were united with catgut sutures. A V-shaped opening was made at the outer commissure of the eye into sound skin and the eyelid was brought into it and secured by a suture, which was passed from above downward into the wound and there tied. The denuded surface on the neck was covered by freeing the skin and fascia on both sides and suturing them to the island of undisturbed skin which was left when the flaps were removed. The wound being thoroughly dried was dressed with boracic acid, and the dressing being secured in the usual way the patient was placed in bed, where she remained for eight days. Many of the sutures were absorbed on the sixth day, the whole of them were removed two days later, and complete union had taken place in the wound. The dressing was scarcely soiled during the healing process. The result was very gratifying to all concerned.

A LARGE DOSE OF MORPHINE.

By W. S. GROOM, M.D.,

BRITT, IA.

September 22, 1893, I was called out of bed to go into the country to see Mrs. P——. I found her in great distress and unable to describe her symptoms very accurately. So thinking to relieve her distress and make my diagnosis afterward, I gave a hypodermic of ¼ grain of morphia, which I repeated in ten minutes, as there was not the slightest result. In twenty minutes I prepared the third dose, but I naturally hesitated in giving it. I asked her if she ever took any opiate? She said, "Yes." "How often?" I asked. "Every day." "How much?" "Thirty grains." Well that staggered me, but after careful investigation I found it to be correct. She showed me an ounce bottle of P. & W. label, said that she took that much every sixteen days. She showed me a ½-ounce bottle that she had opened in the morning, and prepared her morning dose, but she was unable to retain it. I prepared a solution of fifteen grains morphia in very hot water, and gave it hypodermically. It filled my hypodermic five or six times. The result was magical. One ounce P. & W. morphia every sixteen days beats the record of any case I ever heard of.

FRACTURE OF THE HEAD OF THE FIBULA BY MUSCULAR ACTION.

By D. B. HORTON, M.D.,

BATAVIA, N. Y.

The only excuse in offering a report of this case is its extreme rarity in practice, and the peculiar scientific interest connected with such an accident. I was called to see E. E——, aged sixty-four, on the morning of January 29, 1889, and as I entered his room he stated that he had broken his leg. I asked how he knew it was broken, and he replied, "Because I felt it and heard it snap, and cannot walk upon it." I readily diagnosed a fracture of the head of the fibula of the right leg, three-fourths inch from the upper extremity of the bone. The fragments were separated one-half inch, but could be easily brought together and crepitus obtained. As he said that nothing struck his leg and there was no abrasion of the skin, my curiosity was excited, and I drew out the following history of the case: While coming home the night before, walking over a bad sidewalk, his right foot caught in a hole in the walk, causing him to stumble six or eight feet, and finally fall off the side next to the fence. On attempting to rise he found his leg useless, and he crawled along, and by the aid of a piece of board finally reached home, fifteen or twenty rods distant. It seems that while falling, and just at that particular time when the knee was twisted outward, leg slightly adducted and slightly flexed upon the thigh, and the foot on the walk, and he, still in an upright position and making a desperate effort to save himself from falling, heard a snap like a bone breaking, and his leg gave way. After a careful study of these parts it will be plainly seen that this position is the only one in which this accident could take place without traumatism. The

head of the fibula is so protected by the external tuberosity of the tibia that only by the leg being bent upon the thigh is it in a measure exposed, and then by a violent contraction of the biceps the bone gives way at its weakest part. I found by flexing the leg upon the thigh to about forty degrees that the parts were easily retained. I applied a compress and bandage for a few days, and then a plaster-of-Paris bandage for four weeks, holding it in this flexed position, obtaining bony union and good result.

TREATMENT OF CEREBRO-SPINAL MENINGITIS.

By T. J. HUTTON, M.D.,

SHENANDOAH, PA.

THE uniformly successful results of the following plan of treatment for this malady has been one of the chief joys of my professional life.

The intense cerebral form is usually attended with constipation that is almost obstipation: here open the bowels with calomel or turpentine enemata. The mild constipation met with in some cases of the cerebro-spinal form of malady is easily controlled by mild laxatives—phosphate of soda in tepid milk, or simple warm-water enemata. I write now of the cerebro spinal form, and the essence of the treatment is: Put the patient into a mild dozy condition by small doses of bromide of potassa and opium, graduated to the age of the patient and repeated often enough to maintain the dozy condition. Draw a good blister over lower dorsal spine by cantharidal plaster sized to suit the age. Keep hot flat irons or bottles filled with hot water to the patient's feet. Feed the patient every hour or two with an ounce or few ounces (according to age) of warm milk and eggnog alternated with beef-juice—not beef-water. A suitable doze formula for a patient aged ten or twelve years would be about as follows:

℞. Potass. bromid. ..... 3 jss.
Sol. opii comp. (Squibb's). ..... 3 jss.
Syr. zingib.,
Aq. caryophy.,
Aq. pur. .....āā q.s. ft. ʒ iv.
M. S.: A teaspoonful every two or three hours by day; less often by night.

A suitable eggnog formula is as follows:

℞. Granulated sugar..... 1 tablespoonful.
Pure rye whiskey ..... 1 tablespoonful.
Fresh milk ..... ½ tumblerful.
A fresh egg well beaten up.
Hot water enough to fill a common-sized tumbler.

What will this treatment do? One thing it will not do—it will not enrich undertakers. I have practised since 1871; have in that time treated quite a few cases of this malady; have had no death to date.

A CASE OF ENTEROLITH.

By W. C. PHELPS, M.D.,

BUFFALO, N. Y.

I FIRST saw the patient three years ago, when she was suffering from a severe pain in the abdomen on the right side. There were some induration at the seat of pain, but it soon passed away and no operative procedures were attempted, though an exploratory incision was thought of. After this attack she was in good health excepting a pain, of a neuralgic character, in her left arm, which was almost always present. She was in her usual health until June 21st, when she was taken with a severe colicky pain. I was called to see her, and relieved her with a hypodermic injection of morphine. She was able to ride out that day in the evening and thought that she had entirely recovered. On the morning of the following day, however, she was again attacked, and began to pass bloody mucus from her bowels. Thinking that a dysentery was being developed I ordered one and one-half ounce of castor-oil. In three hours she had a movement of the bowels, and a large stone, weighing over half an ounce, was passed, with immediate relief to all her symptoms, including the pain in the arm, which had been very severe during the continuance of the pain in the abdomen. I think that this stone was impacted in the small intestine, and was the cause of the patient's illness three years ago, and that it passed into the large intestine at the time of her recovery, and had since been lodged in that portion of the alimentary canal until it was finally expelled by the dose of castor-oil. Authors state that it is always a matter of years during which enteroliths are forming, even as long as thirty years—generally not less than six.

A CASE OF PSEUDO-RABIES COMPLICATED BY DELIRIUM TREMENS.

By J. D. GRISSIM, M.D.,

HOUSE PHYSICIAN TO ST. JOSEPH'S HOSPITAL, PATERSON, N. J.

ON August 12th a man, twenty-six years of age, a plethoric German, applied for admission at St. Joseph's Hospital, giving the following history:

Eight weeks previously he had been bitten by a dog, whose teeth penetrated the coat and clothing, sinking into the shoulder and leaving marks over the deltoid and in the axilla. The dog had shown no signs of rabies but was immediately killed. The patient declared he thought no more of the matter until some weeks later when some of his associates suggested the possibility of hydrophobia and depicted to him the horrors of the disease. He became apprehensive concerning his welfare, and his anxiety increased more and more until he began drinking heavily to drown his thoughts, which he said constantly dwelt on this one subject.

On the evening before entering the hospital, August 11th, he had difficulty in swallowing a glass of beer, which increased his mental worry, and he spent a sleepless night. Upon admission to the hospital I found him exceedingly nervous and morose, dysphagia present to a well-marked degree, preceded by tremor of the entire body, and he objected seriously to the customary bath, both before and during the process. He was admitted at 4 P.M. At 7 P.M. he was given chloral, 20 grs.; bromide of potassium, 3 j., which dose was repeated at midnight, with ¼ gr. morphine hypodermically. He passed a very restless night, sleeping for only a few moments, waking with terrified cries. On the following morning the patient was able to drink milk with ease, but when he was urged to drink water dysphagia was more marked and accompanied by peculiar sounds from the throat. Temperature, 99⅘° F.; pulse, 85 per minute. He was exceedingly nervous and restless all day. In the afternoon he had hysterical spells of sobbing and terror without any apparent cause, and said that he realized that he was acting peculiarly but could not control himself.

Afternoon temperature, 100° F.; pulse, 90. At 9 P.M., besides the bromide and chloral, he was given ½ gr. morphine hypodermically, after which he slept a short time.

At 11 P.M. he attempted to jump out of the window, but was caught by an attendant. I was summoned, and found the patient violently delirious, imagining he was pursued by police and that they were concealed in the room. He made frequent efforts to get to the window, muttering incessantly in German and English, and in fifteen minutes became so violent that I was obliged to summon three attendants I had stationed conveniently, and it required the united efforts of us four to hold him in bed until he could be chloroformed and a canvas sheet applied. As a result of his violent and persistent struggles his heart action was about 200 per minute, and his breathing labored and irregular. His face was much congested, and his skin very hot and dry. I thought venesection advisable, and while he was still under chloroform I drew a quart of blood from the median basilic. This blood was at first very dark and thick, but later became normal in color and consistency.

His pulse improved in character, but not in rate, and respiration became less rapid, but was still very irregular. He was given twenty-five minims of tincture of digitalis hypodermically, but it had little apparent effect upon the pulse. As the effects of the chloroform wore off, his struggles continued, and he died four hours after the first appearance of delirium from sheer exhaustion.

The case is one of interest from the fact that a very peculiar neurotic affection should have been rendered fatal by an intercurrent disease brought on by the patient's efforts to cure himself.

RESULTS FROM CIRCUMCISION.

By JOHN W. S. McCULLOUGH, M.D.,
ALLISTON, ONT.

Among others, two cases are called to my mind, illustrative of the value of circumcision, by the article of Dr. Rosenberry, in the Medical Record of August 11th.

Case I.—Boy, aged three and a half, very intractable, incontinence of urine day and night; treated with strychnine and belladonna, then with strychnine and atropia sulphate. These, however, failed. The prepuce was very long and tight, so I performed circumcision, using cocaine anæsthesia. A complete recovery from the incontinence followed.

Case II.—Boy, aged one month. Two years ago a child in the same family, then of the same age as the present patient, had severe indigestion, for which no treatment was of any value. I advised circumcision, as the boy had a tight and elongated prepuce. The operation was refused, and eventually the child died. In the present instance the child had indigestion, screaming fits at night, and failed to thrive. The prepuce was, as in the former case, long and tight, the orifice being extremely small. My advice that circumcision be performed was concurred in by the consultant, Dr. J. Harlan Reed, of Horning's Mills. I did the operation without any anæsthesia, and used a couple of silk sutures on either side of the central tear in the mucous membrane. The wound healed without any trouble and the child's indigestion and screaming were gone almost from the hour of operation. Used when required, there is no doubt of the value of this little procedure.

PILOCARPINE IN THE TREATMENT OF ACUTE AND CHRONIC URTICARIA.

By R. ABRAHAMS, M.D.,
NEW YORK.
ATTENDING PHYSICIAN TO MOUNT SINAI HOSPITAL, OUT-DOOR DEPARTMENT.

My humble desire in this paper is to call the earnest attention of the profession, particularly at this time of the year, to the admirable action of a drug in a disease which very often baffles the therapeutic ingenuity of the general practitioner as well as the specialist. The symptom of symptoms which the physician is called upon to combat in acute or chronic urticaria is the terrible itching. It is hardly an exaggeration to say that this symptom is responsible for the many constitutional disturbances frequently observed in this disease. The hydrochlorate of pilocarpine promises immediate, certainly eventual, relief and cure of all the symptoms and the disease itself in a great majority of cases.

I do not wish to be understood as saying that pilocarpine is a specific for urticaria in the sense that mercury is in syphilis or quinine in malaria, for, in the nature of things, no drug can be a specific in a disease of a varied and obscure etiology. But the claim is emphatically made that the alkaloid will cure where all other means will fail to relieve. Not to weary the reader with a long list of successful cases, observed both in private and dispensary practice, I shall mention but three, which are at present most prominent before my mind, occurring respectively in a man, woman, and child. Let, however, every man try for himself and be convinced. Let him employ this treatment after all other treatments prove of no avail, my request being only that he observe the conditions hereafter mentioned, which are so essential to a good result.

Case I.—A friend of mine, a physician, had an attack of acute urticaria. The burning and itching were distressingly intense. He was restless and sleepless, without appetite and patience. Before I saw him he had exhausted pretty nearly the entire list of remedies. After one hypodermic injection of pilocarpine he was relieved. The second injection cured him.

Case II.—A lady, about fifty-five years of age, suffered a very severe attack of urticaria. Her body and face were one mass of burning wheals. I saw her in the morning; gave a hypodermic injection of pilocarpine. At my second visit in the evening, all I found left of the hives was the thankful victim to tell the tale of her bygone woes.

Case III.—A child, two and one-half years of age, suffered from a lichen urticaria for the last two years, always worse in the summer. I found the child in a most miserable condition, pale and emaciated, no sleep at night from the perpetual itching and scratching. Treatment was kept up at various places and by various men during the entire period. Six weeks ago I saw the little sufferer for the first time and at once put him on pilocarpine internally. A week later the child's rest was undisturbed at night and his appetite markedly improved. To-day the child is free from all urticarial miseries, and his health is in a first-rate condition.

The employment of pilocarpine in the treatment of urticaria is not entirely new, nor yet is it very old. The latest works on skin diseases and materia medica, as far as I could ascertain, hardly mention it. My first lesson in this new application of the drug I learned in Dr. Lustgarten's skin clinic (Mount Sinai Hospital Dispensary), with which I was connected as assistant for nearly three years. The drug there is used freely and satisfactorily, and on more than one occasion Dr. Lustgarten, in private conversation, extolled the virtues of pilocarpine in the disease in question.[1] I am, however, well aware of the fact that this medicinal agent failed to be of service in the hands of some good men, even skin specialists. The failure, it seems to me, is due to one of three causes: Either the urticaria was badly complicated by eczema, the result of scratching or strong applications, or the diagnosis was questionable, or the alkaloid was impure. A case in point: After relating my excellent results with pilocarpine in urticaria to an able physician he promised to furnish me with corroborative evidence from his extensive practice. A few days later he returned with evidence—of disappointment. At my request I was shown the patient, and found the fair dame a victim of a mild scabies instead of hives.

Now as to the mode of administration and dosage. An adult should get it under the skin, and a child by mouth. The dose for an adult is from one-sixth to one-half a grain, repeated every day or every other day, or oftener. For a child one year old, the dose is from one-twentieth to an eighth of a grain in distilled water every evening at bedtime. For a child from two to three years old, the dose is from one-fifteenth to one-sixth of a grain. By administering the alkaloid gradually, feeling one's way as it were, no untoward accident should be anticipated. Adults, however, seem to be more susceptible to its influence than children. A good precaution is to remain with the patient after exhibiting the medicine from fifteen to twenty minutes, and when given to children mothers should be instructed to use a little red wine or claret should the child show signs of weakness. I have seen only one man that complained of marked weakness after a hypodermic injection, and two patients were severely salivated. The first was restored by a little

[1] Brief reference was made by the doctor to the action of jaborandi in urticaria at a recent meeting of the New York Dermatological Society (Journal of Cutaneous and Genito-Urinary Diseases, June, 1894).

claret and the other two were relieved by holding ice in the mouth.

It seems that in order for pilocarpine to be palliative or curative in acute or chronic urticaria, it must make the patient sweat freely. I found that free perspiration is promptly and with a comparatively smaller dose produced in an adult than in a child, and herein is my guide to the increase or diminution of the dose.

To sum up: 1. Pilocarpine in urticaria is the drug *par excellence*. 2. Be sure of the diagnosis. 3. Before instituting your treatment, clear off complicating lesions. 4. Get a pure drug. 5. Have patience. 6. Push the drug to the point of tolerance.

In conclusion, I wish to state that in two cases of jaundice where the itching was quite annoying pilocarpine proved useful, and I have seen it also allay the burning and tingling sensations in other affections of the skin.

156 Clinton Street.

UNSUCCESSFUL EMPLOYMENT OF POTASSIUM PERMANGANATE IN A CASE OF MORPHINE POISONING.

By C. MONROE McGUIRE, M.D.,

WALSENBURGH, COL.

Having read in the Medical Record, and various other medical journals, of the many experiments with potassium permanganate with varying results, I have been urged to report my case, where the so-called antidote was tried in a case of an adult and found wanting.

I submit the following brief report, and will warn my professional brethren to beware of trying any new remedy until its physiological and pathological effects are known to be as represented, as I came near losing my patient by relying on permanganate of potassium.

On the evening of March 15th I was called to see Mr. M——, a travelling salesman, married, and of good habits. He had lost his position through no fault of his own, and was very despondent. I found him nervous, pale, nauseated; had been vomiting at frequent intervals for the past three days. No appetite, bowels torpid, dull headache; he said he did not think he needed medical aid, but his wife felt uneasy about him.

When I had examined him thoroughly and prescribed for him, I did not feel that I had struck the "key-note" as to the cause of his present condition. I assured him he would doubtless be kept in for two or three days only.

On the evening of March 16th, at 5.30 o'clock, I was hastily summoned to see Mr. M——. The messenger said he was dying (during the day it was known he had lost his position, so my first thought was, Mr. M—— has made an attempt to take his own life rather than stand the disgrace of being discharged). On entering the room I found him lying upon a bed in a profound coma, face cyanosed to a purplish dark color, breathing almost entirely suspended, heart slow and strong. He had taken the opiate only about one hour before, as it was afterward ascertained; the pupils were markedly contracted; he could not be made to recognize the loudest of noises. I was sure he had taken morphine. I lowered his head, raised a window, and practised artificial respiration till he breathed, then I gave him atropine sulph., gr. $\frac{1}{75}$, hypodermatically. Thinking the morphine had been all absorbed, as I did not know at what time he had taken it, I did not use the stomach-pump. Finally I got him to swallow, and gave him FE. ipecac. ʒ ss. by the mouth, which in the course of an hour and a half produced marked emesis. During this time several persons had come in, and we had him upon his feet supported by two or three men, and made him walk, or carried him rather, in a perpendicular position until he finally could speak and breathed without being told or made to do so by pressure over the chest. I gave him strong black coffee and more atropine sulph. while he was being walked around, until he seemed out of danger or in a favorable way to recovery. About this time my wife, Dr. Eva M. McGuire, came in and corroborated my diagnosis. The patient's wife, of course, expected him to die and asked me several times what I thought of his chances for recovery; I told her I thought he would live, but to satisfy her sent for my friend, Dr. W. H. Earnest.

At the time the messenger went the doctor was in the country, so it was some time before he came, perhaps three hours after I had first been called. The doctor hearing of the probable ingestion of an opiate brought with him one pound-bottle of potassium permanganate. He also corroborated our diagnosis. He proposed potassium permanganate in three- or four-grain doses by the mouth, saying that he was not at all sure of its antidotal powers, but thought it worth trying. I agreed, though I felt sceptical of it. At the time when Dr. Earnest came, I had not given any atropine for some time, and Mr. M—— was so that he recognized all who came in. At this time he was propped up in bed, when we gave him three or four grains of potassium permanganate. He seemed to be in a fair way to recover, though the pupils were still markedly contracted. In perhaps twenty minutes after the ingestion of the potassium permanganate Mr. M—— sank into a deep coma; he could not be roused by shouting into his ears, the breathing stopped, he became cyanosed to a dark color, and life seemed to be gone. I again practised artificial respiration, but this time without any success at all. He had not breathed for two or three minutes. During all this time Drs. Earnest and Eva McGuire stood by, when finally I raised him up and Dr. Earnest and I carried him in a perpendicular position to the veranda, where we gave him to two strong men who supported him in an upright position till he breathed. When he had been walked in the open air I gave him another hypodermatic injection of atropine, gr. $\frac{1}{60}$, and strychnia, gr. $\frac{1}{15}$. This was repeated in an hour, when his pulse became stronger again. He complained of dryness of the fauces and called for water frequently; we gave him strong coffee too. At 10 P.M. Drs. Earnest and Eva McGuire went home. Relays of men walked with him till 12 P.M., when I allowed him to go in the house and sit up in a chair. I had to tell him to breathe for about one and one-half hour longer, when I allowed him to go to sleep, and he only breathed seven to eight times per minute. I finally let him go to bed, but sat by him till 6 A.M., when he breathed twelve times per minute. He made a good recovery, and confessed that he had taken morphine.

PSORIASIS TREATED BY THYROID EXTRACT WITH NEGATIVE RESULT.

By CHARLES E. NAMMACK, M.D.,

VISITING PHYSICIAN, GOUVERNEUR HOSPITAL, NEW YORK.

Julius R——, aged seventeen, tailor, native of Russia, was admitted January 4, 1894. Eleven weeks before admission an eruption appeared on his face and extended over the entire body, including the scalp, with the exception of the palms and soles. Considerable itching attended the eruption. The case presented the classical appearance of psoriasis universalis, with a more extensive distribution than the writer had ever before seen, the patches assuming all sorts of features as to size and shape, and every region of the body being covered. The mucous membranes were not affected. The patient had never had a previous attack, nor could it be traced to either parent. He is an underfed and overworked boy, employed in a "sweater" shop. He gives no history of alcoholism, rheumatism, syphilis, or venereal disease. He was treated by arsenic, alkaline baths, and external inunctions in the usual way, until January 23d, when my colleague at the New York Hospital Out Patient Department, Dr. Prince A. Morrow, called my attention to Byrom Bramwell's report of the efficacy of thyroid extract in similar cases (*British Medical Journal*, October 28, 1893). A specimen was obtained from the New York Biological Institute, and administered in gradually in-

creasing doses, hypodermatically, up to twenty-five minims twice a day, without the development of any physiological action from the extract, and without any perceptible influence on the eruption. All other medication had been stopped at the time the thyroid administration was begun. Through the kindness of Dr. Morrow another preparation of thyroid extract, prepared by Dr. Crary, was then obtained, and the patient was given five drops of this twice a day, and the dose increased gradually until he had taken fifteen drops twice each day. No other medicine was used. He received the usual ward diet and was allowed to be out of bed. The thyroid extract did not increase the bodily temperature, nor accelerate the pulse, but a noticeable effect of its administration was a marked increase in the daily excretion of urea, confirming the results reported by Dr. Ord and Mr. White (*Therapeutic Gazette*, January 15, 1894). If it be true that thyroidectomy increases the toxicity of the urine, and that the function of the thyroid body is an excretory one (MEDICAL RECORD, February 24, 1894, p. 246), these observations have a peculiar interest, and the use of thyroid extract a wide therapeutic field. In this particular case it carried the amount of urea excreted, on a diet not very rich in nitrogen, up to from 875 to 1,025 grains daily. Its effect upon the eruption, however, was negative, such improvement as occurred being fairly attributable to the rest and hospital life. It was therefore discontinued on the fifty-fourth day.

29 EAST TWENTY-FOURTH STREET, March 22, 1894.

PREMATURE LABOR BEFORE THE SIXTH MONTH—SURVIVAL OF THE CHILD FOR ONE WEEK.

BY W. J. HILL, M.D.,

STATESVILLE, N. C.

UPON July 13th last I was called to see Mrs. C—— at two o'clock in the afternoon, and at five o'clock the labor was completed in a natural way. Very little blood was lost; the womb contracted tightly, and the woman did well generally. On January 18th she menstruated last. Everything went along all right until she was three and a half or four months gone, when she took a trip of twelve miles into the country in a rough wagon. Not being in the habit of riding she became very tired. That night "her sickness" came on her. Being somewhat alarmed, she came home at once, believing she would miscarry. From this time on until her confinement the loss of blood was continuous, amounting at times to flooding. Despite my efforts to control it by keeping her in bed and the free use of ergot and other remedies, I was importuned from time to time by herself and husband to bring on labor, but insisted on waiting as long as her life was not endangered, until the child was viable. Very little quickening was felt. In fact, she was so sure it would be born dead that she did not prepare any clothes for it.

The presentation was the one most usual. Though the second stage was not protracted, yet the child was livid and presented every appearance of being lifeless. As is my habit, I suspended it head downward, and in a moment I saw evidences of life. By my aid in artificial respiration it soon began to cry; I then in a few moments had it snugly wrapped in soft warm wraps, and had it laid away. After I had seen that the mother was made comfortable, I turned my attention again to the child; I refused to allow it to be washed for two days, neither did I allow it to be handled to dress it. It was at first allowed the sugar cloth, then it was put upon its mother's milk, which was milked from the breast and fed to it from a bottle and nipple. Afterward it took the breast. It slept well, bowels were regular in their action, as were also the kidneys. It lived for seven days. The nails were only shaped, but the infant had plenty of hair. No vernix caseosa present. It was born with the membrana pupillaris present. It measured eleven and a half inches and weighed one pound and two ounces. The morning after it was born I could cover the face from view with a silver dollar. The mother has borne four other children, and always went to full term. The child was allowed to get cold, and this I think caused its death. Upon examination I found that a considerable portion of the placenta bore evidences of having been detached for some time. There was very little fluid in the sac; it was of a brownish color with considerable sediment in it. This fluid also came from the mouth and nose of the child at birth. The mother made an excellent recovery.

TREPHINING FOR TRAUMATIC CLOT.

BY GEORGE G. HOPKINS, M.D.,

SURGEON TO ST. JOHN'S HOSPITAL, ETC., BROOKLYN, N. Y.

CHARLES BOLTS, aged twenty-seven; sea captain, single. Admitted to hospital September 16, 1893.

Eighteen days previous, during a severe storm, he was struck on the eminence of the left parietal bone by the main boom and knocked overboard; he had strength enough to catch a rope and was pulled aboard. His yacht was shortly driven ashore and wrecked, and he was pulled ashore by some of his crew in a semi-conscious condition. Later he lost consciousness, but for how long a period I have been unable to ascertain.

On admission to the hospital the patient was unable to give a clear statement of anything that had occurred during the eighteen days that had elapsed since the injury had been received. From friends who had watched him constantly, it was ascertained that his actions were very erratic. He would insist on going long distances to see friends, and when he reached his destination he wondered why he had come. He would stand for hours in the rain and refuse shelter, but would not or could not give any reason for so doing, etc.

He complains of headache, constant and severe, the greatest pain being over the site of the traumatism; has persistent nausea with vomiting and constipation.

Examination: Head found to be symmetrical on both sides. Tenderness exists over left parietal bone about two thirds distance from external auditory meatus to median suture. Pupils are equal, responding slowly to light. Pulse, 75; temperature, 97.5° F. Urine, sp. gr. 1.016, acid, amber color, no albumin, no casts, no sugar.

There is no tubercular, rheumatic, nor syphilitic history. Had drank heavily a few weeks before the injury.

September 21st.—To this date the patient had been on the medical side under care of Dr. J. E. Langstaff, who transferred him to the surgical side, and he came under my care. Vomiting very frequent. Bowels obstinately constipated. Headache persistent, and at times delirium.

Ordered,

℞. Potassii iod..... gr. iij.
" brom..... gr. vj.
M. S: T.i d.

℞. Chloral hydrat ..... gr. iij.
Spir. chloroformi ..... v.
M. S: T.i.d.

Pul. glycyrrh. comp., ʒj., repeated every four hours until a free action of bowels is secured. Hydrobromate hyoscin., gr. $\frac{1}{100}$ p.r.n.

22d.—Bowels moved freely. Condition improved.

23d, A.M.—Has retained both medicine and nourishment for twenty-four hours; P.M., had a severe attack of vomiting.

24th.—Three movements during the night. Retains nourishment and medicines. Slept seven hours. The first sleep of more than a few minutes since admission to the hospital.

October 7th.—Patient steadily improved till to-day. He was allowed to leave his bed and go about for an

hour. Nausea, frequent vomiting, and headache; returned.

8th.—Consultation by Drs. Burge, Rand, Rochester, Langstaff, Fairbairn, and Hopkins. The consultation decided "symptoms due to shock," Dr. Hopkins dissenting, considering "symptoms due to clot." I considered operative interference imperative. Not being sustained, concluded to wait as symptoms were abating.

11th.—Symptoms all aggravated again.

12th.—Headache constant and severe. Determined to trephine over the seat of pain.

Operation at 3.30 P.M. I operated in the presence of the staff, assisted by Drs. Wallace, Simmons, and Hotchkiss. Anæsthetic, ether. A curved incision was made through the scalp over the left parietal region, the skin and subcutaneous tissues were dissected backward, the periosteum was elevated, a seven-eighth inch trephine was applied over arm centre, and a button of bone removed. The dura mater was slightly lacerated by the trephine. Dura incised and turned back, and a clot one fourth of an inch in diameter found partly organized and removed. There was a pretty free hemorrhage, but it was easily controlled by pressure. Pad of iodoform gauze inserted in the wound after douching with Thiersch's solution. Dressing, iodoform gauze; returned to bed. Button of bone not returned, having become soiled.

13th.—Comfortable night, temperature, 100° F. Has lost power of right arm.

14th.—No motion in arm or leg on right side, some difficulty in speech. Headache entirely gone, nourishment retained.

15th.—Wound dressed, found perfectly aseptic. When dressing was removed power returned to both leg and arm.

19th.—Leg motion good, but that of arm impaired. Speech thick. Headache only occasionally, and very slight. No vomiting since the operation. Sleeps all night, and hallucinations and delirium have disappeared. His general condition is greatly improved.

December 17th.—Patient discharged from hospital. Right leg has recovered perfect power, speech is good. Full power in right arm has not returned, though he can use it for all ordinary purposes, and it is steadily improving. Headache gone, eats and sleeps naturally.

June 22, 1894.—He has now been at sea for some months and is perfectly well, but lacks strength in the three smaller fingers of the right hand.

This case bears strongly upon a theory I have long held, that there are many simple or weak-minded and epileptic people in the world who have received a traumatism, and who, had they been promptly relieved by surgical procedures, would have been saved from a living death.

TREPHINING FOR DEPRESSED FRACTURE TWO INCHES IN DIAMETER.

By GEORGE G. HOPKINS, A.M., M.D.,

BROOKLYN, N. Y.

Leonora B——, aged five. Admitted to St. John's Hospital May 4, 1894, apparently in a dying condition. She had been kicked by a horse over the right temporal and parietal region, causing a fracture which was two inches in diameter and depressed at its centre full half an inch.

I proceeded to operate under chloroform, assisted by Drs. Rand, Fairbairn, Simmons, Search, and Panton. All aseptic precautions were observed, an oval incision was made extending beyond the line of fracture on all sides, which was two full inches in diameter. The trephine was applied at the junction of the two smallest fragments and a ⅞ inch button of bone was removed, the greater portion being taken from the sound bone. The smallest piece was removed with forceps, as it had penetrated the cerebral substance, which was oozing, and to have raised it would have lacerated the cerebrum still more. Before the bones could be elevated to their normal position it was necessary to remove from the larger fragment its outer edge for an inch in length by a quarter of an inch in width.

The difficulty of replacement did not end here, as a third fragment was removed before satisfactory reposition could be accomplished. As a result of the operation, we had removed one piece of bone half an inch square, and portions of bone around two-thirds of the circumference of the fracture. A silkworm gut drain was introduced between the overlying tissues and the calvarium. The edges of the muscles and skin were partly sutured. A piece of sterilized gauze was introduced at right angles to the silkworm gut, and the flap closed over it. Douches were of Thiersch's solution.

The wound was left undisturbed until the ninth, when it was found perfectly aseptic, no pus having formed. Gut and gauze were then removed. On the eleventh the wound was again dressed, and is still perfectly aseptic. On the thirtieth the wound was entirely healed.

The temperature never rose above normal. The child was allowed to go home. Its mind is perfectly clear and has been throughout.

"No injury to the head is so slight that it may not cause death, and none so severe that a patient may not recover from it."

PERMANGANATE OF POTASSIUM IN OPIUM-POISONING.

By C. H. CALLENDER, M.D.,

NEW BOSTON, MASS.

H. C. W——, seven years of age, child of well to do parents. Has never been a very healthy boy, and on the night of June 16th suffered from a slight bronchial trouble which kept him awake the greater part of the time. At 7.30 A.M. of June 17th the nurse gave him, as she supposed, two drachms of arom. syr. rhei. He had then eaten a good breakfast, played around a few minutes, complained of being sleepy, and gone to bed.

His mother, who was at this time confined to her bed in the same room, knowing that he had not rested the previous night, thought it nothing strange that he should be sleeping and paid little or no attention to him. At 10.50 A.M., some three hours after taking the dose, I was hurriedly called (my office being less than seventy five yards from the patient's home). I found the child in his night-dress lying in his nurse's lap; face pallid, shrunken, agonized; pulse almost imperceptible; respiration very slow but not stertorous; skin covered with cold sweat. Asked what he had taken, and was assured that there had been nothing but some cough-syrup during the night, and the rhubarb.

Knowing the child as well as I did, and having seen him while visiting his mother the evening before, being sure that independent of the cough he was in better health than he had enjoyed for a long while, I felt so certain that he had obtained poison in some manner and of some sort that, without asking any more questions or making any more careful examination, I hurried to the office for stomach-pump, medicine case, etc. I was probably not gone two minutes, but before I was again in the house the mystery had been explained, and the bottle labelled rhubarb had been found to contain laudanum.

The pupils were very much contracted. Considering the length of time since the dose had been taken I thought the pump would be of little avail, and gave a hypodermic of whiskey, ordered some hot water in bottles, and then the thought of permanganate of potassium came to me I was not certain that I had any of the drug, but fortunately found about fifteen grains, and dissolved this amount in three ounces of water. It was probably not more than five minutes after the nurse, on going to the boy's cot, found something was wrong, before I had given him the first injection of permanganate. I used the ordinary hypodermic syringe holding xxx. minims, and injected deep every time.

At 10.56 A.M. I gave the first injection in the left arm.

The pulse, which was very unsteady, was 46; respirations, 8 to the minute. Twenty-five minutes later a second injection was given in the same arm, and ten minutes after this the pulse was 54 and more steady; respiration 12.

At 11.30 A.M. a third injection was made in outer part of the thigh. While introducing the needle I thought he attempted to move the leg a little. Five minutes later I put my finger on the eyeball and the lid closed quickly. I noticed the pupils had dilated considerably. Ten minutes later I called the child by name loudly, as I had done a number of times before. He opened his eyes and made a slight attempt to start up, as a person would when suddenly aroused from sleep.

The fourth and last injection was given at a quarter to twelve o'clock, and he fought against it pretty strongly. Pulse now 68; respiration 16 to 18.

Although he still seemed drowsy, he easily recognized the people in the room, and would call them by name when requested to do so. With a person on each side we now walked him about the room for a while. At noon I felt safe in leaving him, and returning in one hour's time found pulse, respiration, and eyes practically normal. I saw him again in the evening, and with the exception of some little pain at the points of injection I could not see but that he acted and felt as well as ever, and he has continued in good health to date.

The case is very much like one I witnessed while a student, some eight years ago, that proved fatal. The child, who was but eight years of age, took but little over a drachm of laudanum, was in the hands of a good physician in two hours' time. The coma was not so pronounced as in my case; but in spite of external warmth, friction, heart stimulants, whiskey, and atropia, he never awoke. Therefore, taking both cases in view, I feel just as sure as a person can be of anything in this world that the child owes his life to the permanganate of potash. It was not over one-half hour before the patient began to show signs of improvement, and it was simply wonderful how quickly he recovered after he once began to do so.

A PAINLESS LABOR.

Dr. Robert N. Flagg, of Yonkers, N. Y., writes: "Having attended a painless case of labor in a primipara, I am inclined to ask the question, How often do we see a normal delivery? The rarity of the experience in my practice, as well as in that of other practitioners with whom I have conversed, leads me to give a brief account of its progress.

"An American woman, born of Scotch parents, aged twenty-one, married eighteen months, ushered in her first confinement by the rupture of the membranes some three weeks before the expected time. This happened in the early afternoon, and at nine o'clock I was sent for, as it was still a question whether the labor was in progress. I found the patient seated up in bed, not as yet having had a pain, but a pressure at intervals of about fifteen minutes. On examination I was surprised to find the os well dilated, thinned out, and every evidence of the completion of the first stage. I returned in an hour, finding the head descending in the O. L. A. position, and very steady pressure about every five minutes. The patient still disclaimed having any pain, and as the pelvis was small and the descent rather slow, I put on the forceps and brought the head down upon the perineum. Before I had time to remove the instruments, the head was delivered, followed by the shoulders and body of a nine-pound boy. The advent of this good-sized baby was greeted by the cheery voice of the mother exclaiming, 'I have not had a single pain.'

"I had watched her through the second stage with great interest, and can say that with the exception of some decided straining and a redness of the face, there was no sign of the labor whatever. The placenta came away easily, and the lying-in period was uneventful. There was no lack of normal sensation about the pubic region, and her husband assured me afterward that she was not devoid of sexual feelings.

"Using the term in a polite as well as pharmacal sense, I consider this defecation of a baby as a missing link, lost in the progress of the race and the over-development of nerve tissue.

"Here was something perfectly natural, but so like the animals that one of my good patients considered it decidedly unscriptural."

A CONGENITAL DEFORMITY.

Dr. James B. Thornton, of Boston, Mass., writes: "From time to time the question of 'maternal impressions' is brought up by reports of interesting and peculiar cases. To vary the monotony of the expression suppose we use that of paternal impression and briefly detail a case to support the term.

"At 4.30 A.M., August 18th, the writer was summoned to attend Mrs. H. L. E——, in her first confinement. Birth was uneventful. On the following day attention was called to a growth on the outer side of the left little finger, near the junction of the middle and terminal phalanges. This growth was a veritable polypus (with a fine pedicle about half an inch in length) and about the size of a large pea, but flattened rather than round. Examination showed it to be of a heloid consistency, and section of pedicle caused but a small drop of blood to appear.

"The paternal interest in the matter was made apparent by the father showing me a sessile growth in identically the same location on his own hand, and which he stated was congenital, and had been a source of much anxiety to his parents, who feared it was of a malignant nature. In his case the tumor had never been operated upon, and had slowly grown smaller from his birth. If I can believe what was told me, the father and mother both made an early examination of the baby in question soon after its arrival, to find their fears confirmed."

MEMBRANOUS ENTERITIS.

Dr. J. M. Ward, of Cornelia, Mo., writes: "At a recent meeting of the New York County Medical Association Dr. Coyle mentioned a case of membranous enteritis where the treatment was correction of diet, rectal injections as a means of cleanliness, and keeping the bowels regular. He does not say that he cured the case by that treatment, and I venture to say that he did not. Early this summer I had a similar case, that I cured by the internal administration of tar, and the daily injection of tar-water. I received the treatment from Mr. David Wark, of New York. Here is what he says:

"'Treatment: Make of North Carolina tar a mass with wheat flour and a few drops of water. Cut into three-grain pills or put in capsules. Give four pills two hours after meals. On retiring use an enema of three ounces of tar-water and retain. In a week or less the bowels begin to move freely and normally, and all the local and systemic symptoms begin to disappear. It takes from two to three weeks to effect a cure. A grain or two of the extract of wahoo as an intestinal tonic, three times a day, completes the cure.'"

A Dog Receives Hospital Care.—The citizens of Bayreuth are mildly indignant because the favorite St. Bernard dog belonging to the Wagner family was treated in the city hospital. Dr. Landgraf, the family physician, and also surgeon to the hospital, received the animal and operated upon him in the regular operating-room of the hospital. The worthy burghers have petitioned the City Council to pass a resolution condemning Dr. Landgraf for his action.

The Universities of Holland, four in number, have 2,972 students, of whom 19 are women.

Society Reports.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 23, 1894.

GEORGE C. FREEBORN, M.D., PRESIDENT, IN THE CHAIR.

Rupture of the Urinary Bladder.—DR. EUGENE HODENPYL presented specimens from a case of extensive rupture of the urinary bladder. They had been removed from a woman sixty years of age, who had stated that six days before her admission to the hospital she had noticed an inability to move the legs or to urinate. She had received little or no treatment up to the time of her admission. She was then found to be somewhat apathetic; the abdomen was distended; there was complete paralysis of the lower extremities, and a small quantity of urine was escaping by drops from the bladder. The next morning she was noticed to be gradually failing in strength, and a few hours later she died. At the autopsy the abdominal cavity was found distended with fluid which was slightly tinged with blood; there was no evidence of peritonitis. At the fundus of the bladder was a linear rupture, almost two inches in length. The bladder was very large, and the mucous membrane was intensely congested. The other abdominal organs and the thoracic organs were normal. The dorsal portion of the spinal cord showed minute areas of softening, and the diagnosis of disseminated myelitis was afterward confirmed by a microscopical examination.

It was quite remarkable that there had been so little discomfort and such slight inflammatory action notwithstanding the amount of urine in the abdominal cavity. It was unfortunate that a bacteriological examination had not been made to determine the presence or absence of bacilli in this fluid. The microscopical examination showed intense congestion of the bladder mucous membrane, but no inflammation. The rupture must have been due to over-distention.

Prostatic Abscess.—DR. GEORGE P. BIGGS presented a number of specimens of prostatic abscess, and made some remarks on this subject based upon a study of the autopsy records of the New York Hospital for the past twenty-five years. In these records he had found ten cases of prostatic abscess, after excluding a few cases which were apparently peri-urethral abscesses, and did not definitely involve the prostate itself. Case of tubercular prostatitis had also been excluded.

The first specimen presented was from a man twenty-two years of age. He had given a history of gonorrhœa lasting for three months before his present illness. He had recovered from his attack entirely at the time of his admission to the hospital. Five days previous to his coming to the hospital, he was seized with retention of urine, and was catheterized daily. On admission, the temperature was 102° F., and the pulse 112. Examination showed a stricture in the deep urethra. On the same day he had a chill and a temperature of 105°. There were repeated chills after this, with a morning temperature of 99° and a evening temperature of 105°. Four days after admission, a swelling appeared in the perineal region associated with some local pain and tenderness. A median incision was made, and considerable pus evacuated from the neighborhood of the deep urethra. The patient died two hours later. At the autopsy, the spleen was found to be considerably enlarged and quite soft; there was an abscess five ctm. in diameter, and numerous smaller abscesses in the left kidney. The right kidney contained two small abscesses. The pelves and ureters were much dilated and inflamed. The bladder wall was thickened, and contained a small quantity of purulent urine. The left lobe of the prostate was the seat of a deep abscess, 1 ctm. in diameter, from which a probe could be passed to a peri urethral abscess 3 ctm. in diameter, located just in front of the prostate. The median perineal incision had passed from the perineal abscess into the urethra. The entire urethral mucous membrane was thickened and covered with a false membrane. There were evidences of a large calibre stricture in the bulbous portion of the urethra. There was a perforation in the left side of the urethra just in front of the urethral orifice, and this communicated with an abscess in the left lobe of the prostate.

The patient died nine days after the infection of the genito-urinary tract, and the cause of infection was probably the catheterization which was necessary before his admission to the hospital.

The second case was that of a man fifty-four years of age, who gave the usual history of stricture. Before his admission, sounds had been passed for the relief of this condition. Ten days before his admission to the hospital, he noticed a swelling in the right perineal region, and this increased rapidly in size. On admission, the temperature was 102.6° F., and his pulse 40, and the urine contained a large amount of albumin with granular casts. An abscess was found on the right side of the anus, and it was incised the next day and considerable fetid pus escaped. After this the temperature was not so high. About nine days after the first symptoms, he developed considerable irritability of the bladder, and examination of the urethra showed a stricture at four inches, which would only admit a filiform bougie. Two weeks after the onset of the first symptoms, external urethrotomy was performed, and the urethra was cut to No. 2, French. After this the temperature ranged from 99° and 102°. The patient became at first stupid, and then unconscious, and finally died of heart failure eighteen days after the performance of the external urethrotomy. No chills were recorded. At the autopsy, the kidneys were found to be the seat of quite extensive chronic diffuse nephritis, and contained also multiple miliary abscesses. The pelves and ureters were distended with purulent urine, and the mucous membrane was inflamed. The bladder was greatly hypertrophied, and the mucous membrane was inflamed and coated with pus. The prostate had been converted into a series of communicating abscesses, which had a capacity of two abscesses. A pin-hole opening connected the abscess with the urethral canal. The pus had infiltrated the connective tissue behind the prostate as far as the pelvic peritoneum, but there was no pelvic peritonitis. There was an incised wound in the perineum which communicated with the bulbous portion of the urethra, but had not opened into the prostatic abscess.

The interesting features were (1) a prostatic abscess developing a few days after the dilatation of the stricture with sounds, and (2) the relatively low temperature, the highest being 102.6°. The cause of death was general urinary infection.

The third case was that of a man fifty years of age. He denied ever having venereal diseases. Four weeks prior to his admission he developed rather suddenly a headache and a temperature of about 103° F. Two weeks later, quite violent symptoms of cystitis appeared, associated with retention of urine. Catheters were used daily for two weeks previous to his coming to the hospital. On admission, his temperature was 100° F.; respiration, 34; pulse, 32. There was a large fluctuating mass felt in the anterior rectal wall. He was catheterized, and fifty-two ounces of urine drawn off. The urine was acid, and contained five per cent. of albumin with considerable pus and blood. He had a chill on the following day, and a temperature of 103.4° F. He developed delirium, and a high temperature persisted. The abscess was opened by a high perineal incision and considerable pus evacuated, but the symptoms were not relieved. He died in a condition of coma a few days later. The autopsy was made thirty hours after death. The spleen was three times the normal size, and quite soft. The kidneys showed moderate chronic diffuse nephritis, and contained a few groups of miliary abscesses in their cortices. The pelves and ureters were inflamed and distended with purulent urine. The blad-

der contained about four ounces of purulent urine; the muscular wall was hypertrophied; the mucous membrane was softened, thickened, and of a greenish color and there was a small mass of fibrous exudation at the base. The prostate had been destroyed by suppurative inflammation, the pus being situated in indistinctly outlined spaces, having ragged walls, and not communicating freely with each other. The incision in the left side of the perineum had drained most of the abscesses on the left side of the prostate, but those on the right side were still full of pus. A sharply defined circular opening, 2 mm. in diameter, was located in the anterior rectal wall, and this communicated with one of the abscesses in the right lobe of the prostate. There was another opening, 2 mm. in diameter, and in the left side of the floor of the urethra just at its beginning. This communicated with an abscess 2 ctm. in diameter, located just behind the trigone. This abscess did not seem to communicate with any of the others. The urethra was congested throughout, but was normal in calibre. The mucous membrane in the bulbo membraneous portion was superficially lacerated in a longitudinal direction, probably from the rough use of the catheter. An immediate bacteriological examination of the pus evacuated at the time of the operation was made, and absolutely nothing found in the cultures except the staphylococcus pyogenes aureus. However, in the fresh pus stained on a slide, there were also some diplococci of uncertain character. Cultures taken at the autopsy developed, in addition to the staphylococcus pyogenes aureus, a bacillus which grew very rapidly and which was regarded purely as a contamination.

The points of interest in this case were, the development of the cystitis and the accompanying prostatic abscess, apparently as a complication of some acute febrile process. He had been catheterized for two weeks previous to his coming to the hospital. The abscess cavities in the prostate were of large size. The one on the right side communicated with the rectum, while that on the left side communicated with the urethra, although neither of the perforations were sufficient to drain the abscesses. The chills were frequent and the fever relatively high. The patient died of general urinary infection including the kidneys. The cause of the suppuration seemed to be the staphylococcus pyogenes aureus, although the other germs found in the fresh pus which failed to grow in the culture, might have had some bearing on it.

The fourth case was that of a Russian, twenty-two years of age, who was brought to the hospital in an ambulance after internal urethrotomy had been done at a physician's office. The hemorrhage had been so profuse that a large catheter had been tied in the urethra, and the patient hurriedly sent to the hospital. The urine was found to be loaded with pus and blood. On the day following his admission his temperature was 104.5°. The next day he had a slight chill, and the temperature remained high. An abscess had then developed in the supra-clavicular region on the left side. He became delirious and died nineteen days after admission. The autopsy revealed an extensive bronchopneumonia and an acute pleuritis. The spleen was three times the normal size and very soft. The kidneys were much congested and swollen, but contained no abscesses. The bladder contained a small amount of pus, and was acutely inflamed. The left lobe of the prostate was enlarged, and on incision was found to contain a large collection of pus. The axillæ and supra-spinous fossæ contained abscesses holding about six ounces of pus. The cause of death was a pyæmia, the kidneys and ureters not being affected.

The fifth case was that of a man twenty-eight years of age, from whom no previous history could be obtained, owing to his being in a comatose condition at the time of entering the hospital. At this time his temperature was normal, but on the following day it was 102° F., and it remained between 99° and 102° F. for a period of three weeks. He remained constantly comatose, and catheters were used to evacuate the bladder. At the autopsy the cause of death was found to be the rupture of an aneurism of the vertebral artery. Both kidneys were congested; the left contained a number of miliary abscesses; the right contained no abscesses. The bladder was intensely congested, and contained purulent urine. The prostate contained an abscess involving not only the prostate but the peri-urethral tissues in front, and communicating with the prostatic portion of the urethra and extensively invading the tissues into the pelvis. In this case, infection was evidently the result of catheterization during the comatose stage. The point of interest was the infection of one kidney only. The abscess communicated with the beginning of the prostatic portion of the urethra. There was no chill, and only a moderate elevation of temperature.

The sixth case was that of a man twenty years of age, who had sustained a fracture of the spine as a result of diving in shallow water. It was necessary to catheterize him. After this had been done several weeks, he developed a chill, followed by a temperature of 104.6° F. He then became delirious. The urine was found to contain blood and pus in large quantities. The temperature remained between 102° and 105° F. for six weeks. He passed into a state of low delirium, and finally died as a result of fracture of the spine and infection of the genito-urinary tract. The autopsy showed the spleen to be large and soft. The kidneys were the seat of chronic diffuse nephritis, and contained many miliary abscesses. The bladder was hypertrophied and filled with purulent urine. There was a large abscess about the neck of the bladder, surrounding the urethra and communicating with the rectum by two small openings, two and a half inches above the sphincter. There was no communication between the urethra and the abscess, or between the bladder and the abscess. The fever was relatively high —102.6° to 104.6° F. for six weeks. The cause of infection was catheterization. The communication was with the rectum, and not with the urethra.

The seventh case was a man thirty-seven years of age, who gave a history of having first had gonorrhœa eighteen years before, and six or seven attacks since that time. He had noticed symptoms of stricture for twelve years. A stricture in the anterior portion of the urethra was cut to No. 31 French. On the following day there was a chill, with a temperature of 104 6° F. The temperature ranged high—101.8° to 105.2° F. for a period of seven days. The autopsy showed the spleen to be large and soft. The kidneys were the seat of multiple miliary abscesses, and both pelves and ureters were dilated and distended. There was a laceration of the urethra just at its communication with the bladder on the left side. The left lobe of the prostate contained a large abscess, which communicated with the urinary tract at the site of the laceration above mentioned—*i.e.*, practically at the urethral orifice. The abrasion was apparently made during life, probably from the passage of a hard instrument. The left knee-joint contained this pus.

The eighth case was that of a man sixty-four years of age, who gave a history of chronic nephritis for four years. He had been frequently catheterized, owing to retention of urine. He died of uræmia, without suspicion that the genito urinary tract had been infected. The autopsy showed advanced chronic diffuse nephritis, but no abscesses in the kidney. The bladder was hypertrophied, and its mucous membrane thickened and ulcerated. There were abscesses in both the lateral lobes of the prostate, and also in front of the prostate. There was in this case simply an involvement of the bladder and of the prostate, the pelves, ureters, and kidneys not being affected.

The ninth case was that of a man forty-two years of age, who had had gonorrhœa twelve years before coming under observation, and constant gleet since that time. He had applied at dispensaries for retention, and

had been catheterized and treated with sounds without avail. Examination showed a stricture located at the bulbo-membranous junction, and a smaller one near the meatus. The latter was cut. Following this there was a chill and a temperature of 101.8° F. The temperature fell to 99.4° on the following day, but rose again to 102.2° F. The urine was diminished in quantity. He died eighteen days after admission. At the autopsy, the spleen was found to be quite large; the kidneys were the seat of advanced pyelo-nephrosis, but there were no abscesses in the kidneys. The ureters and pelves were dilated and inflamed; the bladder wall was considerably hypertrophied and its mucous membrane acutely inflamed. The bladder contained a small amount of purulent urine. There was an incision in the floor of the anterior portion of the urethra. The stricture at the bulbo membranous junction had not been operated upon in any way. There were two openings, one on each side of the urethra, just at the beginning of the prostatic urethra, and they led into abscess cavities in the prostate, having a capacity of one ounce. In this case, the pelves, ureters, and bladder were infected, but the connective tissue proper escaped.

The speaker said that out of the ten cases of prostatic abscess in which the records had been examined, six gave venereal histories, three denied such a history, and in one no record was made in regard to it. Catheters were used and appeared to be connected with the infection in five cases. In one case there was a question as to the use of the catheter, no record having been made in regard to this point, yet no good explanation had been offered of the source of infection. In three cases the infection was directly due to the operation of internal urethrotomy. In one the symptoms followed dilatation of an old stricture by sounds. Seven of the abscesses were large, and three comparatively small. Five of them communicated with the urethra only, and all of these communicated with the urethra in the posterior portion of the prostatic urethra. One communicated with the rectum alone; one with both rectum and urethra; and three small ones did not communicate with either urethra or rectum. In five cases there was cystitis and double pyelo-nephritis; in one, cystitis and pyelo-nephritis of one kidney; in one, cystitis and pyelo-nephrosis; in one, pyæmia with pyelo-nephritis; in one, pyæmia without pyelo-nephritis; and in one case there was no infection beyond the prostate. In three of the cases the temperature ranged between 104° and 105° F.; in five between 99° and 102° F.; in two there was no record of temperature, but it was probably quite low.

In all but one of the cases there was a history of the use of instruments in the urethra some time previous, or the infection followed immediately upon the operation of internal urethrotomy. There was evidently secondary infection, and it was quite possible that the severity of the symptoms might depend somewhat on the organisms producing the infection. The possible causes of death were pyæmia, septicæmia, peritonitis, or a simple genito-urinary infection exclusive of other diseases. Septicæmia was likely to occur in cases where there were large abscesses without secondary deposits of pus. Peritonitis might occur from extension of the inflammation to the connective tissue of the pelvis to the pelvic peritoneum.

The prognosis should be guarded, owing to the frequency with which prostatic abscess was associated with general infection of the urinary tract. In eight of these cases the kidney was involved. It would seem that the most frequent cause of death was infection of the upper portion of the urinary tract.

Dr. Samuel Alexander said that much credit was due to the reader of the paper for the way in which he had grouped his facts. There were acute abscesses occurring as a result of gonorrhœal infection of the urethra, and they were, perhaps, more common than the chronic. They were due to secondary infection, either through sounds or injections, and were marked clinically by the sudden onset of the symptoms—a chill and a much higher temperature than was usually present in the chronic cases. The diagnosis was not difficult if a rectal examination were made; the symptoms could be quickly relieved by operation. He thought that all the cases just presented should be grouped as chronic abscesses, because the condition which predisposed to the infection was chronic. Most of the cases there seemed to be a previous pathological condition of the urinary tract. In half of the cases there was a stricture of the urethra, and the autopsy showed secondary changes in the bladder and kidneys, thus predisposing to general infection of the genito urinary tract. One striking peculiarity of this series of cases was the large size of the abscesses. In most of the cases he had seen clinically the abscesses had not been nearly so extensive. We should distinguish between abscess of the prostate and peri-prostatic abscess. Regarding the prognosis, he would say that it depended more upon the pre-existing condition of the urinary tract and the severity of the infecting cause than upon anything else. Death was most rapid and the abscess formation most extensive in those cases in which there was a serious lesion of the urethra, causing obstruction, congestion, and infection. Regarding the mode of infection in the cases in which no catheter had been used, the speaker said obstruction in the urethra, by causing urinary overflow and congestion, led to infection. This condition occurred most frequently in patients over forty five. The perineal operation was, of course, the one above all others for the relief of prostatic abscess, and the moment such an abscess was suspected an opening should be made in the perineum. Where suppuration extended upward into the prevesical space this operation was necessary; but in addition to this it was essential, as shown in the cases under discussion, that dissection should be made between the prostate and rectum and all the pockets evacuated, and the abscess cavity curetted and treated aseptically.

Dr. Thomas H. Manley said that in those cases in which the spinal cord had been destroyed in the lumbar region as the result of injury, there were various modes of death, the most common being by infection of the genito urinary tract. Owing to the long, tortuous urethra of the male, this mode of death was much more common in males than in females. While he thought all must agree as to the good results of careful asepsis, the fact still remained that some subjects were morbidly sensitive to the passage of any instrument into the urethra. In cases of over-distention from paralysis of the bladder he had found that, in spite of every precaution, infection and death were liable to result.

Dr. George P. Biggs said that the cases reported in the paper were old ones, and in most of them infection had occurred from catheterization by the patient himself, or by some incompetent person, previous to the admission of the patient to the hospital. The importance of making a free opening should not be overlooked, for one of the cases showed that, notwithstanding the communication of the abscess and the perineal opening, drainage was not at all adequate to the needs of the case.

Congenital Absence of One Kidney and Ureter.—Dr. R. G. Freeman presented specimens from a case of the above. They were taken from a child aged ten months, who up to a few days before death had been perfectly well. It then developed croup, was intubated, and died from broncho-pneumonia and extension of the membrane. The right kidney and right ureter were absent. The left kidney was quite large, weighing three ounces. Three such cases had been presented to the Society—one by Dr. Northrup, in 1887; two by Dr. Thacher, in 1892; and one by Dr. Hodenpyl, last year. The condition was said to be quite rare, and the left one was the one most commonly absent.

The Society then adjourned.

Many Suicides of boys, from twelve to sixteen years of age, have recently been reported in London.

New Instruments.

AN IMPROVED CILIA FORCEPS.

By CHARLES H. MAY, M.D.,

CHIEF OF CLINIC, DEPARTMENT OF OPHTHALMOLOGY, VANDERBILT CLINIC, COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT OF COLUMBIA COLLEGE, NEW YORK.

Epilation of the lashes is a very simple process; but frequently it is rendered difficult and tedious on account of the improper and clumsy shape of the cilia or epilating forceps in the market. In blepharitis and in trichiasis in which epilation is performed there is no difficulty in pulling out the coarser lashes; but the fine and short hairs often give us much trouble, especially when they become moistened and slippery from tears and discharges of the lids; then we are apt to find that the forceps no longer catch.

To obviate this difficulty, I have had a forceps constructed which is a modification of one I purchased

of Windler, in Berlin, and which is referred to as "Brecht's" in his catalogue. In general shape it resembles the cilia forceps now in use; it differs merely in the construction of the extremities or points. These are claw-shaped, delicate, having a width of 2½ mm. The edges are curved, one being convex, the other concave; they are so arranged, through a slight difference in curvature, that pressure exerted in clasping the instrument tightens the grasp upon the hair and holds it firmly, without any danger of cutting it off. The instrument has given great satisfaction and has done away with the annoyances already mentioned. It is manufactured by Meyrowitz.

692 Madison Avenue, New York.

AN IMPROVED CONICAL RECTUM SPECULUM.

By ROBERT W. MARTIN, M.D.,

PHILADELPHIA, PA.

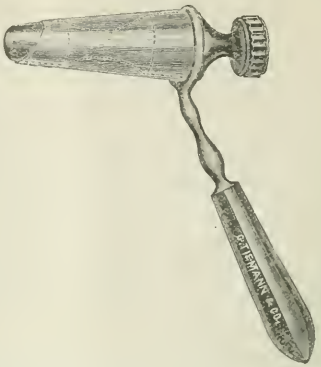
An instrument of precision applicable in the treatment of two out of every three patients who seek the office of the physician for treatment of the more ordinary diseases of the rectum is certainly a *desideratum*.

When I presented my new ano rectal speculum to the profession through the *Times and Register* (October 5, 1889), five years ago, I thought I had an appliance as nearly perfect as it was possible to make. And, indeed, for very many of the applications and minor operations within the rectum it was, and remains to me, indispensable. But longer use made it manifest that something was needed to supplement its usefulness. Consequently, a year ago, taking the ordinary conical speculum and enlarging its field of view, I had it made on the model of a symmetrical cone, truncated at a small angle, so that the obturator would fall into position without the trouble and delay of adjusting it to some particular line or mark on the base of the cone. The outer end of the obturator was supplied with a milled head of large diameter to facilitate its removal.

The base of the speculum was fitted with a firm handle of extra length and large grip adjusted to what was conceived to be the proper angle. Thus was made an appliance with which any portion of the lower half, or more, of the rectum and intra-anal tissues might be brought into view by successive small portions for the purpose either of inspection or treatment.

I have never used an appliance that has given me such supreme satisfaction in treating follicular ulceration, polypoid, and other small growths, which constitute a very large proportion of the cases of anal and rectal diseases the physician is called upon to treat in the ordinary routine of office practice. The cut gives a sufficiently clear picture to render further description unnecessary.

In the cut the handle appears attached at a greater angle than experience has shown to be desirable, the drawing having been made from the first specimen of the



speculum manufactured. It is now made with the handle attached at a much smaller angle with the axis of the speculum, making it as efficient in treating a patient with protuberant buttocks and deep seated anus as one with wide-apart tuber ischii and a more accessible anus.

I am indebted to Messrs. George Tiemann & Co. for their precision in executing my designs for the correction of what was faulty in the old and the addition of what is new to form a perfect new out of a faulty old form of speculum.

117 South Sixteenth Street, August 15, 1894.

A SNARE WIRE RECEIVER.

By GEORGE E. ABBOTT, M.D.,

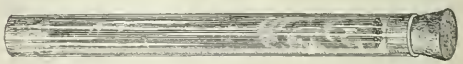
NEW YORK.

This can hardly be called a new instrument. Yet to some it may be a new and useful adjunct to their snare.

The usual routine, now, is to find the spool of wire, then the cutting forceps, guess at the length, cut, drop the spool, say something, wind up, and with difficulty fasten the springy wire, adjust the wire, and find it makes too small a loop, or, worse yet, too large a one, for the screw has been "run up" as far as possible; but the polyp has not yet been cut off and the snare is thus anchored in the patient's nose, to be delivered only by main force—of course not by pulling upon the whole snare, but by a straight pull upon the rod, through the cannula thus severing the growth.

The better way is to make a trial wire first, allow its ends to bend up at least a quarter of an inch, so as to hold well, "run up" the screw and be sure the entire loop will be drawn within the cannula, so as to completely divide the tissue within its grasp, with a few turns to spare for possible slipping or stretching of the wire.

With this as a sample, straighten the wire of the spool, and cut fifteen or twenty lengths.



Now cut a glass rod (scratch with edge of file and snap it in two) one inch longer than the wires, so as to allow of corks at either end; heat the ends red hot so as to round off the sharp edges; put in the bottom cork and cut it flush with the end of the glass, now the wires and the cork at the top. You will thus have saved time and labor, and very much annoyance when the patient is anxiously waiting for you to operate. A simple tube can be made by rolling some writing paper several times around a pencil or other cylinder.

125 West Eighty-second Street.

Correspondence.

EXAMINATION FOR CANCER-CELLS IN THE LIVING TISSUE.

To the Editor of the Medical Record.

Sir: While reading the article in the Medical Record of August 25, 1894, on "The Cure of Carcinoma of the Breast by Radical Operation," by Dr. William T. Bull, the idea occurred to me, Why not, in operating for the cure of malignant disease, make a microscopic examination of the living tissues of the wound, to ascertain whether all the cancer-cells have been removed. If the examination should reveal diseased structure still there, it could be removed before the wound is closed. If practical and practicable it seems to me that this would be a great advantage to the patient, giving her a better chance for her recovery, and reducing the mortality from carcinoma. It would also lessen the number of secondary operations. Could not a microscope be so constructed that with it the living tissues of the wound might be examined *in situ*, after the growth had been removed and before closing the wound? If this could be done I think it would be very useful, as cancer-cells are frequently left just in the edge of the wound. Of course this is but a crude idea, but I would like to know what the readers of the Medical Record think of it and its practicability.

Albert Seitz, M.D.

McMinnville, Tenn.

SOME SURGICAL OBSERVATIONS OF DR. FR. RAVOTH.

To the Editor of the Medical Record.

Sir: Some years ago Dr. Fr. Ravoth published a small volume containing short papers on a variety of surgical conditions. The book is dated 1873, and issued by Ferdinand Enke, Erlangen.

It is thought that the author's views on varicose veins, varicocele, etc., might be of interest, inasmuch as such procedures are not found in some of the more recent text-books on surgery, and seem worthy of consideration.

In the paper on the "Treatment of Varicocele by Means of a Truss," the author refers to other writers, to the results of treatment of hernia with truss, etc., and states that under pressure of a truss-pad the varicocele lessens in size, the testis soon becomes larger, and more consistent, while the pain in the testis and cord ceases. The enlarged veins being due to the weight of the blood, if by appropriate constriction the vein is relieved from this strain the part below the point occluded will recover itself. He believes that this mild method is more efficacious than the many ways of operative interference, which are not free from danger.

These ideas may be applied to other venous varices, *e.g.*, in the legs. (The treatment of aneurism, by pressure on the distal side of the tumor, may be referred to in this connection.)

The other papers are also of interest to the scientific anatomist, surgeon, and practitioner. In this relation worthy of special notice is his description of the surgical anatomy, with treatment of shoulder and elbow, and dislocations of them. He does not believe that there is, in any sort of sickness or injury, an absolutely pathognomonic sign. Strong disapprobation is expressed for the practice of making a "snap diagnosis," on which follows the hunting up of symptoms to support the *a priori* judgment. On the contrary, the correct method consists in—1, Investigation of the history and cause; 2, inspection; 3, palpation, or manual examination.[1] Such truths will bear oft repeating.

The faulty union of fractured patella is attributed less to imperfect nutrition than to failure in keeping up coaptation, for which bandaging should be applied to the whole limb, and not merely in the vicinity of the lesion.

[1] Loc. cit., pp. 210, 211.

The same ideas apply to fracture of the shaft, etc., of other bones. Bandaging restrains slight displacement of fragments by muscular or other mechanical action, thus allowing the healings to approximate that *prima intentione*.

F. B. Stephenson, M.D., U.S.N.

TWO MORE CASES OF PREVENTIVE INOCULATION OF IMMUNIZED SCARLET-FEVER BLOOD SERUM.

To the Editor of the Medical Record.

Sir: One of my sons, aged seven, being stricken with scarlet fever, I have inoculated, on the second day, two of my other children, who had not had this disease, aged five and two years. The blood serum was taken from their older brother, aged nine years, who had had scarlet fever six years before. Two drops, taken from a blister on his breast, were used for each child, and there was one inoculation only for each. There was no real isolation—separate bedrooms during the night, but free intercourse during the day. Now, the ninetieth day, no infection has been observed.

Albert S. Ashmead, M.D.

New York, August 31, 1894.

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 8, 1894.

	Cases.	Deaths.
Tuberculosis	69	107
Typhoid fever	29	20
Scarlet fever	15	4
Cerebro-spinal meningitis	0	3
Measles	17	0
Diphtheria	110	27
Small-pox	16	1

The Dangerous Anti-Vaccinationists.—One of the most striking testimonies to the mischief that a knot of active anti-vaccinationists can do is shown in the experience of Stuttgart, the capital of Würtemberg, between the years 1864–1869. Stuttgart was the focal point from which radiated anti-vaccination influence, and, in consequence, not only many private citizens but the militia of that city were "unprotected." It had a population of 1,760,000 souls less than New York, yet in the five years indicated there were no less than 11,092 cases and 800 deaths. During that time there were 34 cases in the army of the whole country, but not a death; and now that vaccination and revaccination are not only compulsory, but done under a faithful inspection, the German army is the bright, conspicuous example, shining like a beacon, for all the world to follow. If Germany could build an impassable fence between herself and Russia, the whole country would soon show itself completely freed from the pest; but there is always an immigration from Russia into Germany of persons from that land, where the persistence of cholera shows the inability to cope with epidemics.—Mrs. H. M. Plunkett, in *The Sanitarian*, August, 1894.

Medicaments Derived from Coal-Tar.—As a consequence of the progress made in the manufacture of coloring materials from coal-tar, physiologists and physicians have been able to experiment with a host of new products, some of which have found a place as therapeutic or antiseptic agents. The substances submitted to such experiments are of very diverse nature, but there is observed in them, nevertheless, a limited number of characteristic groupings. They are phenols, acetylated amines, and sulphonated, sulphuretted, iodated, and chlor-

ated derivatives of the aldehydes. Methodical experiments have not been numerous enough, and the data furnished by biological chemistry are not precise enough to allow us to establish any relation between the constitution of these bodies and their physiological properties, provided any exists. Their applications, in fact, exhibit many anomalies. We see products that are very different as to constitution act upon the organism in a similar manner, and substances that are analogous, from a chemical point of view, produce very different therapeutical effects. With the information that we possess upon this subject it is hazardous to draw absolute conclusions. The number of organic bodies proposed as antiseptics or as medicinal products is very large, and one or more new medicaments are observed to make their appearance every day. We can mention but a limited number here, in selecting the most important of them. We have arranged these substances as antithermics and analgesics, and hypnotics and antiseptics. There is nothing absolute about this classification. A large number of these products has at the same time several of these properties. For example, chloral, which we place among the hypnotics, is an analgesic, and is even employed as an antiseptic, and asaprol is at the same time an antiseptic and an analgesic.

1. Antithermics and Analgesics.—Of all the artificial antithermics, antipyrine or analgesine is the most widely used up to the present. It is derived from phenylhydrazine, which is itself obtained by dinitrating aniline and in reducing the dinitro-benzol thus obtained. This phenyl-hydrazine is afterward condensed with aceto acetic acid, and then, finally, the product is submitted to a methylation. We have at last the dimethyl-phenyl-pyrazolon that constitutes antipyrine. It is very soluble in water, and this property permits of administering it under the most varied forms—a quality that is highly appreciated in pharmacy. It must be observed, however, that, as a general thing, solubility has no relation whatever with the quickness of action and assimilation of a medicament. Phenacetine, while being but slightly soluble in water, acts, nevertheless, as quickly as antipyrine. The success of antipyrine has evoked a series of experiments with the object either of preparing substitute antipyrines and of analogous pyrazolons, or of associating it chemically with other substances. In the first order of ideas has been produced tolypyrine, which is a paramethylated antipyrine in the phenylic nucleus, and then chlorated, bromated, etc., antipyrines. In the second series antipyrine has been associated with salicylic acid, and this has given salipyrine. Tolysal is the salicylic combination corresponding to tolypyrine. Apropos of hypnotics, we may mention hypnal, which is a derivative of antipyrine and chloral. Thalline and kairine are quinoleic products that have been proposed likewise as antiseptics. Among the oldest analgesics and antithermics we find acetanilide and antifebrine, which are prepared by treating aniline with anhydrous acetic acid. If, instead of operating with aniline, we start from hydroxylated aniline, that is to say, from a product which is both phenol and amine, and etherify it before acetylation, we shall have phenacetine or phenedine. Thymatecine is the phenedine of thymol, and exalgine is derived from the acetylation of methyl-aniline. Salicylate of soda has been for some time employed as an antirheumatic. Salicylic acid is a carboxylated phenol, that is to say, a body that is at once phenol and benzoic acid. It is prepared by passing a current of carbonic acid over phenate of soda at a high temperature. Several applications have been found for its derivatives, among which may be mentioned salipyrine, that we have spoken of above, and salol, which we shall find among the antiseptics. Asaprol has the same action as salicylate of soda. It is obtained by treating beta-naphthol with sulphuric acid at a low temperature. It is the sulphuric ether of beta-naphthol. It is offered in the state of calcium salt very soluble in water. Under the name of abrastol it has been used as a microbicide.

2. Hypnotics and Various Medicaments.—One of the most frequently employed hypnotics is chloral, which is the hydrate of trichlorated acetaldehyde. An endeavor has been made to associate it with various organic substances. In this way have been prepared: Chloralose, which is a combination of chloral and glucose; hypnal, which is due to the union of one molecule of antipyrine and one of chloral; and somnal, which is obtained from chloral and urethane. Sulphonal is likewise a very efficacious hypnotic, but its constitution has no relation with that of chloral. Chemically, it is called the diethyl-sulphone of dimethyl methane. It is formed by the combination of acetone with ethyl-mercaptan. Trional and tetronal form part of the same series. For skin diseases there have been proposed dermatol, which is the subgallate of bismuth; sulphaminol, obtained by the action of sulphur upon meta-oxidi phenyl-amine; resorcinol, which is a combination of iodoform and resorcine; and lysophane, which is chemically called triiodo-metacresol. Tumenol, thioline, and sulphonated thiophene are designed for the same use. Piperazine, a nitrated product of the closed-chain series, is diethylene-diamine. One of the processes of preparing it consists in causing ammonia to act upon bromide of ethylene. Orexine serves to stimulate the appetite. It is a hydrochlorate of phenyl-dihydro-quinazoline.

3. Antiseptics.—Among the organic antiseptics, we find, especially, bodies with phenolic and aldehydic functions, and halogenated derivatives. Phenol, beta-naphthol and guaiacol are characterized by the phenolic grouping OH directly connected with the benzolic or naphthalic nucleus. The use of a large number of phenolic derivatives has been recommended. Thus, salol is salicylate of phenol, and betol is the salicylate of beta-naphthol. The union of benzoic acid with naphthol gives benzo-naphthol. Abrastol, of which we have above spoken under the name of asaprol, is the salt of calcium of the sulphuric ether of beta-naphthol. It is a microbicide at present proposed for the preservation of wine. Among the phenolic products of less importance we may mention alumnol, sozol, daphtherine, phenoline, cresine, and microcidine. Iodoform is triiodated methane, analogous to chloroform as regards constitution. This antiseptic has, as well known, an insupportable odor. An endeavor has, therefore, been made to substitute odorless and likewise iodated substances for it. Among the bodies proposed to this effect we may mention diiodoacetylene or diiodoform. In order to prepare this alkaline hypoiodites are made to act upon an aqueous solution of acetylene, or water upon a mixture of iodine and carbide of barium, or else by treating acetylene with iodine in the presence of an excess of potassa at a low temperature. There likewise exists a tetraiodo-acetylene. The other iodated derivatives are: Traumatol (iodo cresylol), aristol (iodo-thymal), iodol (tetraiodo-pyrol), and sozoiodol (diiodo-paraphenate of sodium). Formol, which has recently been proposed as an antiseptic, is form-aldehyde. It has the great advantage of being volatile, and, consequently, of penetrating to the very interior of the objects to be disinfected. Ichthyol, anytine, thiol, and thiolinic acid are sulphonated and sulphuretted derivatives of organic and mineral oils employed in this state and that serve as solvents for products insoluble or but slightly soluble.

Among the substances mentioned, a small number only will doubtless receive the sanction of practice, but the road is laid out. On the one hand, syntheses are multiplying with the object of finding new series, and, on the other, the natural alkaloids are the object of numerous studies. With the means now at the disposal of chemistry, it is possible to study the active principles of digitalis, belladonna, and a host of other natural products. We shall certainly succeed in giving such alkaloids a greater energy, perhaps new properties, and even replace them by substances of which the syntheses will be only the results of a study of the products, of their reduction and of their decomposition.—*Scientific American.*

THE TREATMENT OF ABORTION.[1]

By BROOKS H. WELLS, M.D.,

ADJUNCT PROFESSOR OF GYNECOLOGY, NEW YORK POLYCLINIC; FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, THE NEW YORK OBSTETRICAL SOCIETY, ETC.

I AM prompted to write upon a somewhat worn subject by the fact that during the past year I have met with an unusually large number of cases of incomplete abortion which have been allowed to run on until they have developed more or less grave septic conditions, or have become seriously anæmic from the continued bleeding.

These cases, which I might use as illustrative, were none of them from my clinic at the Polyclinic, where we see them only too frequently, and where poverty, ignorance, and often previous treatment by equally ignorant midwives lead us to expect conditions otherwise inexcusable, but were all of them from the upper and middle classes, and were referred to me by intelligent physicians. So it seems, in spite of all that has been said and written in favor of active, efficient, and early interference, many practitioners prefer to take the chances of time and ergot in the hope, sometimes, it must be admitted, realized, that all will finally come right. Others, recognizing the necessity of action, but with an imperfect technique, partially succeed in clearing out the uterus by the aid of the finger or curette, and in the attempt carry infection into the uterine cavity.

It is true that cases of incomplete or neglected abortion do not usually die, either from the continued hemorrhage or from sepsis; they struggle through a period of acute anæmia, or fever and prostration, and finally may recover perfectly, but more often are left with a chronic infection affecting the endometrium or extending also to the tubes and peri uterine structures, a condition which, in the light of modern pathology, we cannot consider inconsequential, knowing that it so frequently leads to the most serious pelvic trouble. The truth of this statement may be easily proved by reference to one's private case-book, or by the records of any large gynecological clinic. Thus, out of five thousand consecutive gynecological cases which have come under my observation at the New York Polyclinic fourteen hundred and ninety-two, nearly thirty per cent. (29.8), had aborted one or more times, and of these five hundred and thirty-five, nearly thirty-six per cent. (35 8), suffered from disease of the uterus or appendages directly traceable to infection following abortion. It is safe to say that the immediate, thorough, and aseptic removal of the ovum, or its fragments, in these cases would have prevented the greater part of this disease and its attendant disability.

Before discussing our subject further it is necessary to understand what we mean by abortion, and to sketch briefly its causes, diagnosis, and course.

Abortion is defined by nearly all lexicographers as "expulsion of the fœtus before the seventh month, or before viability;" but to insure clearness it is advisable to limit the word to its stricter sense, of "expulsion of the ovum before the end of the third month," and to employ the term "miscarriage" for expulsion between that period and the time when the fœtus becomes viable.

Abortion or miscarriage may be from pathological causes affecting the fetal or maternal organism, or may be induced.

Maternal causes may be systemic—from poisons circulating in or conditions impairing the mother's blood, or disturbing the circulation mechanically, as syphilis, malaria, the exanthemata or other fevers of severe type; cholera, poisoning by CO, CO_2, and other gases; salts of certain metals (lead, copper, etc.), and vegetable alkaloids; albuminuria, cholæmia, lithiasis, anæmia; and visceral (liver, lung, and heart) disease affecting vascular tension.

Maternal causes may be local—from retro-displacement of the uterus, pelvic adhesions, endometritis, pelvic or uterine tumors. They may be reflex—from gastric, rectal, or mammary irritation, mental shock, or excessive emotion, exhaustion of nerve-force, as in chorea or in epilepsy.

Fetal causes may be primary or the result of maternal dyscrasia, and include disease of the fetal envelopes, as fatty, hydatidiform, or fibrinous degeneration, or inflammation or hemorrhage of the chorion or placenta, death of the embryo, or any malformation affecting the circulation of the fœtus and causing hydramnion or oligohydramnion.

Finally, abortion may result from combinations of any of these causes. Induced abortion may be accidental, legitimate, or criminal. Accidental causes may be uterine traumatism from blows, falls, wounds, excessive or violent coitus, etc., and we might again include here excessive emotion and mental shock. Criminal abortion may be from general violence, mechanical injury to the uterus or ovum, or from the administration of certain drugs.

The symptoms vary with the time at which the abortion occurs. If within the first six weeks the woman may complain only of a moderate amount of lumbar pain, dull and heavy or cramp like, or there may be no pain and an amount of hemorrhage, which she may consider as simply an excessive menstruation. Very often she does not recognize the passage of any shreds of tissue, or clots, and the abortion passes unnoticed. At other times portions of chorion remain behind, and she comes to the physician complaining of the prolonged spotting or flow. Later, and up to the time when the placenta is fully developed, the lumbar pains are more marked, the cramps more severe and rhythmical, and the hemorrhage much greater in amount. If the abortion be the result of natural causes and the death of the ovum has occurred several days before its expulsion, it usually comes away entire. If the ovum is alive, or if the abortion be induced by mechanical means, the fœtus usually escapes, leaving the whole or a part of the chorion behind.

Bimanual examination shows the uterus enlarged, soft, except during a contraction, the cervix softened and more or less dilated, and often with a portion of the ovum plugging the os. After the expulsion of the entire ovum the pains and bleeding cease and the uterus contracts. If a portion of chorion or placental tissue be retained, the bleeding, pain, and dilatation may continue until it is expelled, or the cervix may contract, the pains become slight or cease, the bleeding stop, and the mass be retained either to disintegrate and come away in the discharge, to become septic, or, exceptionally, to develop into a fleshy mole. Rarely there may be death and infection of the ovum without producing either pain, hemorrhage, dilatation, or foul discharge, the only symptoms

[1] Read before the New York Academy of Medicine, April 26, 1894.

being cessation of uterine growth, followed by irregular slight chills and septic fever.

After the third month the symptoms approach more nearly to those of a premature labor. We have the rhythmic pains, the hemorrhage, which is apt to be more profuse, the dilatation of the os, and, more often, the spontaneous evacuation of the entire contents of the uterus.

Abortion may be considered inevitable when the result of a cause that cannot be removed, when the pains are severe or rhythmical, the hemorrhage profuse, the os widely dilated, or when any portion of the ovum has been expelled.

Threatened abortion may sometimes be averted when the cause is a remediable one, and the pains, bleeding, and dilatation are only moderate. When abortion becomes inevitable one of two things happens, either the uterus empties itself entirely, or a portion of the ovum is retained. In the first case the uterus contracts, the pain and hemorrhage cease, there is a pinkish flow for a few days, involution proceeds normally, and the condition remains practically the same as before conception. If, however, portions of placenta or chorion remain in the uterus the clinical picture is changed. The symptoms noted diminish at first, but do not entirely disappear; the pain may cease for a time and then reappear, and the fragments be expelled, or the os may contract and the fragment be retained until it gradually breaks down and passes away with the discharges. In this latter case the bleeding continues, as a persistent leakage, often for from three to six weeks, and may reduce the patient to an extreme degree of anæmia, though it in itself rarely kills. Very often, and almost certainly, if this incomplete abortion be the result of criminal interference with the ovum, the retained tissues become infected and we have a septic process begun which may induce serious and persistent pelvic disease or directly destroy life. Sepsis is the condition most to be dreaded, the condition to be most carefully watched for, the condition to be most vigorously fought against. We must always be on the watch for its first symptom, and when we recognize it, whether it be as an elevation of temperature, a chill, or a fetid discharge, we must remember its probable source and explore the cavity of the uterus. Septic material may be there even though the cervix be perfectly contracted and hard, though there be no hemorrhage, no discharge, and possibly no other local symptom. I have seen several instances to which this description would apply, one of which ended in death. But the sepsis is not usually of a virulent type, the case runs on, the woman recovers from the immediate danger, but the fever, the hemorrhage, the infection, have interfered with involution; the uterus remains large, heavy, and soft, and is apt to become retro displaced; the infected mucosa, thickened, soft, and friable, becomes the seat of a chronic endometritis which may at any time lead to tubal and ovarian trouble, and the woman suffers indefinitely from the metrorrhagias, the pelvic pains, and the systemic depreciation which accompany these conditions.

Treatment.—A local examination is always imperatively necessary when any of the signs of impending abortion appear. Then, if the symptoms are not marked, if the pains are slight and irregular, the bleeding moderate, the os not much dilated, and the cause one that can be remedied, as, for instance, retroversion, we may hope by absolute rest in the recumbent position, by the administration of full doses of opium, and viburnum by suppository, or morphia hypodermically, and by the replacement of the displaced uterus, to carry the patient through her period of danger and allow the gestation to continue. If the cramps are regular and well marked, the hemorrhage considerable, and, particularly, if the os be dilated, these hopes will not be realized, the loss of the ovum becomes inevitable, and it is our duty to hasten its expulsion. As the method of procedure now varies according to the period of gestation, we may draw a line of division at the end of the third month and consider the case as either "abortion" or "miscarriage."

Abortion.—As the uterus before the end of the third month is still comparatively small and will not allow the accumulation of any considerable amount of blood in its cavity, the use of the tampon is sometimes permissible before the expulsion of the fœtus, not so much to check bleeding as to excite more vigorous expulsive contractions. When expelled, the patient is to be put in the dorsal position on a Kelly pad, the vagina and cervix thoroughly cleansed by a douche of hot soap-suds rubbed into all folds and crevices by the fingers, and followed by irrigation with 1 to 4,000 warm bichloride solution. Then a strip of sterile iodoform gauze is carefully packed into the cervix and the vagina tamponed. This packing is removed in from eight to twelve hours, and afterward the ovum will be found loose in the vagina or in the dilated os. If at this time no portion of the ovum be expelled, that is, if its envelopes be still intact, the packing may be carefully repeated. If any portion of the ovum has been expelled, the remainder should be removed at once, either with the finger, which can seldom be used at this early period, with the ovum forceps, or with the dull curette.

If there be reason to believe that the abortion has resulted from criminal interference, if the case has been allowed to run on for many days, if there be endometritis or any form of sepsis, the os should be dilated, preferably after the administration of an anæsthetic, the fragments of the ovum removed, and the whole interior of the uterus scraped carefully and thoroughly with the sharp curette, washed clean with a strong watery solution of iodine and packed with a strip of sterile iodoform gauze. This gauze should be removed in twenty-four hours and the vagina irrigated. If septic symptoms continue, the uterine cavity may be again irrigated with the iodine solution, and a fresh strip of gauze carried to the fundus.

The effective and safe manipulation of the curette and gauze in this manner presupposes on the part of the operator a certain amount of skill and familiarity with its use.

Miscarriage.—After the third month the use of the tampon for hæmostatic or other purposes is reprehensible, as the uterus is then larger and dilatable, so that a dangerously large amount of blood may accumulate in its cavity. If the hemorrhage from a miscarriage is moderate, the treatment may be expectant for a limited time until the entire ovum or the fœtus be expelled. If the fœtus alone be discharged, the remaining portions of the ovum should be immediately removed with the finger, aided, if necessary, by the ovum forceps or large curette. If the hemorrhage be profuse there should be no delay, the os should be dilated and the uterus cleared out at once. Where there is sepsis the indication is for the use of the sharp curette, irrigation, and packing, as already described.

When we have legitimate reason for inducing abortion it is best done by immediate clearing out of the uterus after anæsthesia and rapid dilatation, the uterus being washed clean and a strip of gauze introduced for drainage. When miscarriage becomes necessary the preliminary dilatation is usually best secured by the employment of an aseptic tupelo tent of the largest size that can be inserted into the os, then, if the ovum be not spontaneously and completely expelled it is removed digitally or with instrumental aid.

To avoid danger and secure success in these manœuvres it is necessary that they be done aseptically and by one accustomed to surgical cleanliness. The hands and arms of the operator should be scrubbed for five minutes with a stiff brush with soap and hot water, and then soaked for the same time in a 1 to 1,000 bichloride solution. The instruments can either be wrapped in a towel and boiled at the time in a weak solution of soda for fifteen minutes, or may be carried already sterilized, and laid on a sterilized towel ready for use. A strip or strips of sterile iodoform gauze should also be prepared and wrapped in a sterile cloth.

Tupelo tents may be sealed separately in small enve-

lopes and baked for half an hour, and are then ready for use when wanted. The Kelly-pad requires most careful attention, and must be thoroughly washed in running water, rinsed in the bichloride solution, and carefully wiped dry each time after use. The fountain syringe used for irrigation may be scrubbed in hot water and soaked in bichloride, or boiled if used where there is a suspicion of sepsis. The patient, after having had her bladder and bowels emptied, is to be placed in the dorsal position on a table; or the hips may be brought to the edge of the bed, a firm bearing surface for the Kelly-pad being secured by a table-leaf, ironing-, or lap-board; and the external genitals and vagina thoroughly cleansed with hot soap-suds, two fingers being used to rub over the mucosa of vagina and cervix. This should be followed by irrigation and rubbing with a 1 to 4,000 bichloride solution. The parts adjacent to the vulva and the exposed portion of the pad are then covered with wet sterilized towels and the operation performed.

In conclusion, I may state my position briefly as follows:

Recognizing that any interference with the uterine cavity must be looked upon as a possible source of infection, and must be made aseptically and with antiseptic precautions to be free from danger, I strongly urge that in every case where abortion or miscarriage begins acutely and from natural causes, the ovum be removed by the finger, ovum forceps, or curette, within twenty-four hours after the abortion be considered inevitable, if the entire ovum be not then already expelled, complete expulsion being indicated usually by cessation of pain and hemorrhage. In cases where a portion has been expelled, where we find serious hemorrhage, where the ovum is dead, where we have reason to suspect criminal interference, where there has been continual spotting, foul discharge, or fever, the uterus should be explored and emptied at once, as any delay greatly increases the risk of sepsis. The sharp irrigating curette, followed by gauze drainage, should always be used where there is septic material present, or where the endometrium is diseased, in other conditions the finger or a dull instrument is sufficient.

71 West Forty-fifth Street.

A Reminiscence of the Late Professor Hyrtl.—A correspondent of *The Lancet* says that the famous anatomist who has just died at Vienna was always considered an eccentric man because his dress, his manners, and his mode of life differed in some respects from those of other people. It was particularly his time worn garments that made him conspicuous, and he used in his walks the same soiled blouse which he wore while engaged in his laboratory or in gardening—his favorite hobby. This characteristic of Hyrtl gave frequent occasion for ludicrous incidents, at which he himself used to laugh most. A few years back, when he was still in possession of his eyesight, he was accustomed to walk to Liesing, a charming Viennese suburb, where, in the beer-garden of the brewery, he refreshed himself with a glass of its well-known beverage. One afternoon he entered the garden and seated himself near a table at which a few merry Viennese burghers were engaged in diminishing the contents of a dish of stewed fowl. These gentlemen had no idea of the identity of the newly arrived guest, and after eying his simple twill suit came to the conclusion that he must be an inmate of the Liesing asylum for the poor. A good portion of the meal having been left uneaten, one of the guests called the waiter and told him to take what was left to the poor man sitting near them. The famous *savant*, appreciating the joke, ate a few morsels and, after expressing his thanks, left the garden. A few moments later two waiters carried in a big bowl from which the heads of champagne bottles were protruding. "We have ordered no champagne!" cried the burghers, and their astonishment may easily be guessed on their being informed that "the inmate of the local asylum for the poor" had sent them the champagne as a mark of his gratitude for the stewed fowl. and that the donor was no less a personage than Professor Hyrtl.

SOME RECENT MEASURES IN THE TREATMENT OF EPILEPSY, WITH SPECIAL REFERENCE TO THE USE OF OPIUM.

A Year's Experience with Flechsig's Plan.[1]

By JOSEPH COLLINS, M.D.,

NEW YORK.

VISITING PHYSICIAN TO THE HOSPITAL FOR NERVOUS DISEASES; ATTENDING PHYSICIAN TO ST. MARK'S HOSPITAL; INSTRUCTOR IN NERVOUS AND MENTAL DISEASES IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

The treatment of epilepsy to day is about as unsatisfactory as it was ten years ago. That is, a decade that has witnessed a considerable addition to our knowledge of the causation and pathogenesis of this disease has seen no striking addition made to its therapy.

It is not presumptuous to say that notwithstanding the persistency with which other measures have been advocated and the extravagant results claimed for them, that to day bromide of potash would not be exchanged for all the other means combined. I do not mean to decry the value of other measures, nor in any way to deprecate their claims in the treatment of this disease, but merely to state what I believe to be a fact.

That there is no dearth of activity in searching for a more curative agent than the bromides in this disease one can satisfy himself by glancing at the literature of the subject from year to year. Although many agents are recommended but few are chosen, after a more or less thorough trial. Among the measures recommended within the past few years those deserving of consideration have been more particularly, 1, borax; 2, simulo; 3, antipyrin and antifebrin; 4, nitro-glycerine; 5, anti rabic virus, under which may be included for purpose of convenience the "organic extracts;" 6, the various combinations of the bromides.

Among those recommended, but having very little claim for their consideration, are 1, hypnotism; 2, hydrastinine; 3, salicylates; 4, duboisine, picrotoxin, cannabis Indica, belladonna, etc.; 5, amylene hydrate; 6, osmic acid and sclerotinic acid.

Since Gowers recommended the use of borax in epilepsy twenty-five years ago, it has been used more or less in obstinate cases that resisted the bromide treatment, and in cases where for some reason the bromides could not be administered. It has taken a definite place in the therapeutics of this disease, as is attested by many of the most trustworthy clinicians.[2]

Its efficiency compares in no way with the bromides; but as an alternate and adjuvant of the bromides it is, when given in proper doses (about 3 ij. *per diem*), a useful and valuable addition to our therapeutic resources in this disease. Its efficaciousness is frequently seen in controlling night attacks while the continuous administration of the bromides prevent the day attacks. The drawbacks to its use are the frequency with which it causes distressing attacks of eczema, psoriasis, impairment of the digestion and nutrition, and even toxic effects. Enthusiastic reports of its efficacy and curativeness now and then crop up,[3] but they are generally accompanied by such meagreness of detail or absence of a judicial weighing of evidence, that they are to be taken with circumspection.

The place held by simulo in the treatment of epilepsy does not compare favorably with borax. Since its introduction by Dr. W. Hale White in 1888 it has apparently never been extensively used. Although White's report of its use in seven cases was encouraging, Eulenberg, who tried it in both hysteria and epilepsy, was not favorably inclined to it. Given in doses of from a half to two drachms of the tincture three times daily, it will, in

some cases, especially of haut mal, give gratifying results, as it has done in one patient at present under the writer's observation. It in no way compares with the bromides.

Antipyrin and antifebrin have been used more extensively in epilepsy than have most new remedies, and in many cases with gratifying results. Lemoine[1] was struck by the value of the first of these in a case which always occurred at the menstrual period, in one associated with migrain and in another of the type of epilepsia larvata or psychical epilepsy. McCall Anderson and Jack report a case of traumatic epilepsy cured[2] in three months by the administration of antipyrin in doses beginning with five grains three times a day and increased one grain a day. The cure was effected when the patient reached a dose of twenty-five grains. It is unnecessary to comment on this case, except to repeat that a case diagnosed, treated, and recorded as cured all within six months should not be taken too seriously.

Salm's[3] experience with antipyrin was not so satisfactory. In fact he thought the results of its use were quite negative. When given in conjunction with the bromide of ammonium, as has been recommended by Wood, it has given very gratifying results and is attested by Potts,[4] May,[5] and Dana.[6]

A combination of antipyrin with the other bromide salts is probably as serviceable as the combination with bromide of ammonium. Amade[7] reported cessation of attacks for four months in moderate epileptics under this treatment. The general consensus of opinion in reference to antipyrin and antifebrin is that the former is preferable, and when given in from five to ten-grain doses three to four times daily it materially enhances the value of the bromides in the treatment of idiopathic epilepsy, particularly in the less aggravated clinical forms.

Nitro-glycerine has been used to a considerable degree in idiopathic epilepsy. It has been specially recommended in cases that are attended with vasomotor aura. One of the most recent writers who calls attention to its use is Osler.[8] It is most serviceable in cases of petit mal and must be given in large doses, two to five drops of a one per cent. solution, and in such doses it is apt to produce intensely disagreeable symptoms. Its value as a therapeutic agent in epilepsy is slight.

Attention was first called to the beneficial effects following anti-rabic inoculation of epileptics by the cessation of attacks in two children who had been inoculated for rabies by Pasteur.[9] Other cases showing the beneficial results of this form of treatment have been reported by Charcot,[10] Giovanni,[11] and Ariostigni.[12]

It is distressing, however, to have to repeat that these cases were reported too early to be of very much service in determining the value of anti-rabic virus as a form of treatment.

It should be remarked here that some of the cases (Charcot's) were shown to gatherings of medical men merely to demonstrate the effect the inoculations had in checking the attacks temporarily. It is sufficient comment on this way of breaking epilepsy to say that the results of its use, limited though it has been, nor any theory on which its efficacy might possibly be based, have not appealed to the medical profession. A more recent treatment of epilepsy, and one which has, to my mind, absolutely no *raison d'être*, has been introduced by Babes, of Bucharest, and Gibier, of New York. It consists of the hypodermatic injection of the extract of the cerebrum of the sheep, freshly prepared. Although the two investigators quoted above have made serious claims for its efficacy, it is probably no exaggeration to say that this agent is as nearly useless in the treatment of epilepsy as any substance which a physician essays to employ with a considerable éclat can possibly be.

Not even the remotest rational explanation can be advanced for its use. The substance cerebrin has no physiological action which would suggest it to be an anti epileptic agent. At the present day no one will gainsay the statement that the "organic" extracts depend for any activity that they may possess on their chemical constitution. And when introduced into the system they act and can only act just as analogous chemical substances obtained from other sources do.

No analogy between the use of the thyroid in myxœdema or the use of the thymus in pseudo-hypertrophic paralysis can be advanced to explain the use of cerebrine in epilepsy. The brain is not a secretory organ, as are the thyroid and thymus, and its constituents are easily separable by the chemist. These chemical constituents, or as many of them as are not inert, are responsible for any change that the patient has in his symptoms while being subject to treatment by these extracts.

The report of cases of epilepsy treated by this method by Babes is so glowing and enthusiastic, and the statement of his results are so indefinite that one need make no comment.

Gibier has published two articles in which he details the results that he has obtained. A careful examination of his report will show that the results barely warrant him in his conclusion, a very modest one, "That the method is beneficial in adding to the favorable effects derivable from other therapeutic agents."

Everyone who has much to do with the handling of epileptics knows how susceptible they are to new, and especially novel, methods of treatment and how frequently the attacks are for quite long periods amenable to such procedures. The personal factor in the handling of the cases reported by Gibier will probably account to a considerable degree for the amelioration of symptoms that they present. Further it may be said that there is scarcely a remedy that has been advocated for epilepsy that has not, in the hands of its advocate, given far better results than has brain injections. I do not wish, however, to criticise it harshly, but merely to express an opinion as to its entire worthlessness and uselessness.

The various combinations of bromine, such as bromide of camphor, of nickel, of lithium, of strontium, of arsenic, ethyl bromate, rubidium-ammonium bromide, etc., have had their advocates and are in many cases of great service, not only as adjuvants to other plans of treatment but as exchange materials for the bromide of potash and soda when the system does not well tolerate the continued tenancy of the latter.

Ferè has recommended the bromide of strontium, but others, with the exception of Deny,[1] who have utilized this suggestion, have not been able to corroborate his good opinion of the drug. Halsted, however, reports with some favor his use of this salt. The bromide of zinc and the bromide of nickel have both been extensively used. The latter, originally recommended by Dr. Costa, was found to be quite useless by Bourneville,[2] who gave it a very extensive trial. Bromide of zinc has been given by Hammond, Charcot, Bourneville and other clinicians, but there is so much uncertainty about this salt, both in regard to its dose and its action, that it would be better not to consider its use at all. For instance, it has been recommended by the writers mentioned above in doses varying from 5 to 30 grains, while a recent number of the *Pharmaceutical Gazette* stated its dose to be from one half to one grain. Ethyl bromate has been recommended by Donath[3] in doses from 30 to 40 drops three times daily and increased to twice this amount if the stomach will stand it. He recommends its administration with oil of peppermint or in capsules.

Corroborative evidence of Donath's estimate of the value of ethylene bromate is given by Olah,[1] who finds that the attacks are milder and less frequent, and that it does not produce bromism. The objections to its use are its extreme volatility and unstableness.

The less important measures against epilepsy that have been enumerated above may be disposed of very rapidly. If our conception of the pathology of epilepsy is correct, or anything approaching correctness, it is an insult to our intelligence to speak of the curative effects of hypnotism in this disease.

The use of hydrastinine, as recommended by Arkhangelsky,[2] has not been successful in the hands of other physicians.

Whatever virtue the salicylates may have in the treatment of epilepsy should be attributed to their action as intestinal antifermentatives. A fact that is too well known to need emphasis is, that frequently attacks of epilepsy may be diminished nearly fifty per cent. in frequency by treating the alimentary canal exclusively.

Duboisine, picrotoxin, cannabis indica, and belladonna should in no sense be considered of sufficient importance to attempt to combat epilepsy by any one of them alone. They are frequently of use as adjuvants to the bromides, particularly in combating some untoward symptom produced by the latter. Amylene hydrate, which was first recommended by Wildermuth,[3] has been found by Dunn [4] to be entirely useless, and even dangerous, in the treatment of epilepsy. This conclusion is substantiated by Umphenbach [5] and Drews,[6] who found that this drug greatly increased the mental confusion in epileptics and caused considerable disturbance of sleep. It should be dropped entirely from the therapeutics of epilepsy.

Osmic acid has likewise been shown to be of absolutely no use in the treatment of epilepsy. Sclerotinic acid has been tried by Bourneville and Bricon in twelve cases of epilepsy, and in some of these the frequency of the attacks was lessened.[7] It was noticed that some of the patients to whom the sclerotinic acid was administered decreased rapidly in weight. This fact alone would militate against its use in the treatment of this disease.

Of the non-medicinal ways of treating epilepsy, the eye treatment has received the most attention. All neurologists are keenly aware of the fact that epilepsy may be, and frequently is, excited reflexly and that not infrequently the source of this pathologic reflex is some error of refraction, or defect in the eye muscles, and that the correction of this faulty condition will be followed by the relief of the trouble which it caused. They are likewise aware of the fact that although attacks of epilepsy may have been excited originally by defective conditions of the eye, that not infrequently treatment of the eyes alone will not cure the disease, and this for two reasons in particular. First, the eye defect may have been merely the exciting cause in a patient predisposed to epilepsy. That is to say such a patient might have the epileptogenous areas of his brain brought into activity by many other factors, for instance, by fright, fatigue, overeating, over-heating, etc., and the relief of such exciting factors would not cure the disease, no more does the relief of the eye defect. In the second place, if a patient has had a number of epileptic attacks, that is, if the motor cells of the epileptogenous areas have been subject to a repetition of explosions, each succeeding one lessens the chances of recovery, and particularly do they lessen the chances of spontaneous recovery on the removal of the cause which excited the first attack. The cessation of attacks goes hand in hand with the improvement of nutrition of the cortical motorial cells, and all our efforts should be in that direction. Not alone the eye but all sources of peripheral irritation should be carefully and intelligently examined and re-examined. Especially should the highly specialized sense organs be examined and any departure from the *norm* should be labored with till it is overcome. After it has been corrected the physician will find that all his therapeutic resources are still necessary to combating the disease which unfortunately still continues to exist. It is then that the plan of treatment seeking the bettered nutrition of the epileptogenous areas should be employed to its full extent.

The eye plan of treatment of epileptics, even when looked at with a most charitable critical eye, does not deserve the laudations of most of its advocates. It can never be more than a factor in the treatment of the disease. If we should decide to treat epilepsy on the eye plan perhaps it would be best to have a symposium of medical men, each one of whom would combat the factor which he considered the important one. Then, when all are finished, the patient will recover in the hands of the physician who gives him iron, and arsenic and the iodides and other measures that will stimulate hæmatogenesis and tissue repair.

When one considers the unsatisfactoriness of the treatment of epilepsy and the futility of so many of the measures which are periodically lauded as having great and peculiar virtues, it is not surprising that most physicians are animated by a wholesome spirit of scepticism in approaching the trial or consideration of any newly recommended substance. A considerable number are advocated every year, but appeals for their recognition fall on deafened ears, and the freezing reception extended to them cuts them off at their very inception, and thus saves much useless work on the part of the physician and much harmful experience on the part of the patient. Occasionally, however, a plan of treatment is suggested that appeals to us in no uncertain way. One based on a laudable hypothesis, or one that involves no shrivelling of our intellect to understand how it may act, or one that has been tried by an observer who from his labors and reputation deserves to be heard, and who recommends it because he has seen it do good, and offers it to his fellow-workers without explanation. It is to such a plan of treatment that I wish to invite your attention.

About a year ago, Professor Flechsig, of Leipsic, published a short article on a new method of treating epilepsy which in his hands had given most gratifying results. It consists in administering opium in the shape of the extract or pill in large doses for a period of six weeks. The dose of opium in the beginning is from one-half to one grain, and this is gradually increased until the patient is taking fifteen grains or more per day, in doses of from three to four grains. The maximum dose is reached by the end of the first week. At the end of six weeks the opium is suddenly stopped, and for it bromide of potassium or sodium in doses of one-half drachm four times daily is substituted. After these large doses of bromide have been kept up for some time the dose is gradually decreased until the patient is taking less than two scruples per day. The sudden cessation of administering the opium and the exhibition of the bromide is quite essential.

Being cognizant of the fact that opium in small doses when combined with bromides is frequently of great service in lessening the severity of attacks of epilepsy the plan of treatment suggested by Flechsig appealed to me and I determined to give it a thorough trial in a large number of cases selected from private, hospital, and dispensary practice, and examine the results of such treatment at the end of one year. About fifty patients have been subjected to this plan of treatment. A few cases I shall detail, and content myself with presenting the results observed in the others in tabular form.

The twenty cases considered in the first table I had under almost daily observation, and the conclusions reached regarding this plan of treatment is based largely on the facts therein set forth. The sixteen cases considered in the second table I did not have under such

close surveillance. They were very old subjects and my principal desire in subjecting them to the treatment was to determine whether the results would militate against, or corroborate the results obtained in the first twenty cases. In a general way it may be said that the results were not so satisfactory.

A study of Table I. shows that all the cases with one exception (Case 5) were benefited. It further shows that in two cases (Cases 3 and 4) the fits have not returned. The time elapsed in these cases is, however, not of sufficient length to refer to them in any way as cured. And I wish to emphasize the point that, although the attacks have ceased, I do not consider them cured, and they are still taking four scruples of potassium bromide a day. In several of the cases the character of the attack after the relapse was frequently of a different nature than that before the attack. That is the family of the patient or the hospital nurse, as the case might be, would describe them as "mere fainting spells" and make light of them. I have observed, however, as time went on that these "spells" gradually become more severe as the number of attacks increase after the relapse. Another fact which I would point out is, that in every case, almost without exception, the maximum dose of opium was reached and persevered in with comparatively slight trouble. Some of the patients who were cognizant of what they were taking complained rather bitterly and rebelled, but particular attention to the bowels and a good deal of out-door exercise served to keep them moderately comfortable. Sometimes it was necessary to administer strong coffee to combat the drowsiness, particularly during the first week when the opium was being increased rapidly.

While the patients were taking opium there was no marked change in the frequency of the fits. Some of the patients had a lesser number, particularly toward the latter end of the six week's period, while others had them with customary frequency.

Notwithstanding the fact that no sinister results accompanied the administration of opium in such large doses, I feel it incumbent on me to say to any one who would apply this plan of treatment, that the most watchful and scrutinizing care is necessary, especially during the first weeks, until the patient becomes accustomed to the large doses.

The most satisfactory results were obtained in very chronic epileptics, and particularly those who were not responsive to large quantities of bromide. In epilepsy dependent on, or associated with, gross organic lesion of the brain the treatment seemed to give better results than in pure idiopathic epilepsy. By gross organic lesion I mean epilepsy associated with old cerebral hemorrhage and softening and epilepsy associated with defective development.

I can but state my convictions relative to this plan of treatment in the following conclusions:

1. The plan suggested by Flechsig is not a specific in the treatment of epilepsy.

2. In almost every case in which this plan of treatment has been tried there has been a cessation of the fits for a greater or lesser time.

3. A relapse generally occurs in a period varying from a few weeks to a few months.

4. The frequency of fits after the exhibition of opium is, for the first year at least, lessened more than one half.

5. The attacks occurring after the relapse are much less severe in character than those that the patient has been accustomed to having.

6. This plan of treatment is particularly valuable in ancient and intractable cases.

7. In recent cases of idiopathic epilepsy it cannot be recommended.

8. The opium plan of treatment is an important adjuvant to the bromide plan as ordinarily applied.

9. The opium acts symptomatically, and merely prepares the way for and enhances the activity of the bromides and other therapeutic measures.

10. This plan of treatment permits the use of any other substances which are known to have a beneficial action in epilepsy.

I will cite briefly the history of a few unselected cases taken from hospital, dispensary, and private case-books, showing the effect of the treatment. I may say that all of these patients were handled with bromides for a longer or shorter time previous to being put on the Flechsig plan.

Case I. Dispensary.—F. M——, female, colored, aged fourteen. Family history tubercular; personal history good. Never had convulsions when a child; was always bright, vivacious, and smart; talked early and walked early. First attack when eleven years of age; cause unknown; character of attack, haut mal.. Frequency of attacks about three a month and getting more frequent. Character of aura, headache for some hours. Physical condition, good; mental condition, backward; she has a great many evidences of mental deterioration. Head symmetrical; no other somatic evidences of degeneracy.

Put on opium treatment September 20th. Reached thirteen grains a day at end of first week. At this time took thirteen pills at one time and suffered from toxic effect, but recovered without difficulty. Put on kalium bromide, ʒ ss 4. i. d., November 1st. Patient reported once a week till January, then stopped for two weeks. Returned February 8th and said she had had a fainting spell, while the medicine had been stopped. Bromide in 20 gr. doses 4 i. d. continued. No attacks since that time. Result: one attack of petit mal in six months, Mental condition about the same.

Case II. Private.—H. N——, male, aged twenty-two, salesman. Maternal side of family neurotic heritage. Paternal great uncle had epilepsy. Attacks began when he was sixteen years of age. Cause, not attributable. Had one spasm when a child, caused by eating unripe fruit. Was bright mentally and strong physically, as a boy. Character of attack, haut mal. Time of occurrence, always at night. Frequency, in the beginning they occurred about once in six months; now they come once or twice a week. Mentally he is deteriorating, forgetful, depressed; cannot concentrate his mind. Physically not robust.

Put on opium treatment April 30th. Maximum dose, fifteen grains, reached in eight days, and continued till June 16th. No change in attacks in point of form or frequency while taking opium.

June 15th.—Substituted bromide of potassium, ʒ ij. per diem, for opium. Reports once a week.

November 28th.—Three attacks in succession the same night. Had not been taking medicine for five days.

December 18th.—Nocturnal attack.

March 27, 1894.—Reports one attack since December.

Result: Four attacks in nine months. Physical and mental improvement.

Case III.—M. S—— female, nine years of age. One sister died of hydrocephalus. She did not walk till two years of age, and began to talk when six. Attacks first began at the age of three years. They were then of the petit mal character, and gradually increased in frequency until her eighth year, when they were occurring once or twice a week. From her eighth year she has had both petit mal and grand mal. Mentally the patient is quite defective. Evidence of somatic degeneracy well marked.

Patient put on opium, gr. j., t.i.d. for three weeks; then on double the quantity for the next three weeks; then on triple the quantity for the next four weeks. Middle of November put on potassium bromide, 30 grains four times a day.

It is necessary to mention that this little patient was the only one of the entire number that developed symptoms of the opium habit. On substituting the bromides for the opium, such symptoms of the opium habit as diarrhœa, anorexia, restlessness, irritability, and sleeplessness showed themselves, but were easily combated with hydrotherapy and small doses of chloral. She has had no attacks for upward of five months. Mentally there is some gratifying improvement. She helps her mother about the house; can be trusted to go errands and the like. During the administration of the bromide she has had restoratives, such as iron and cod-liver oil, in such quantities as she could dispose of.

Case IV.—M. P—— male, twenty-one years of age; heavy drinker. One brother had attacks for upward of twelve years and recovered at the end of that time. One year ago after a heavy drinking bout he had an attack of pneumonia and while convalescing from this he had his first epileptic attack. After this they occurred two to three times a week, and both in the day and in the night. Has an aura starting from the stomach accompanied by cardiac palpitation. Mental condition good.

Put on opium August 22d and continued for six weeks. Then bromide in 30-grain doses four times a day. Result, no attacks since cessation of opium.

Case V.—H. B—— female, sixteen years of age. Mother died of tuberculosis. Had convulsions when three and a half years of age. Then was quite free from attacks till ten years of age. Talked and walked early and learned easily until her tenth year, when she had severe attacks of haut mal. Three or four months later she had a second attack and since that time they have increased in frequency. Concomitant with the increase in the number of attacks has been mental deterioration, so that now she is quite demented. Three years ago she had an attack of chorea, and while ailing with this, she had a left side hemiplegia which disappeared in about a fortnight. Her mind has been gradually getting weaker, and for the past six months she has had visual and auditory hallucinations. Always before an attack she complains that her eyes hurt her. Evidence of somatic degeneracy, such as stunted stature, torsus palatinus, over exposure of gums, defective lobulation of ears, crowding of teeth, broad, flat nasal arch very apparent. For the past six months she has had at least six attacks a week, for two or three hours after an attack she is entirely *non compos mentis*.

Put on opium January 10, 1894, and for the next six weeks while on opium the attacks were not so frequent as formerly.

February 28th.—Put on kalium bromide. No attacks for two weeks, since then an attack about every fourth day.

Case VI.—A. F——male, aged twenty-two, of neuropathic heritage. First attack of epilepsy when fourteen years of age. Attributing cause, a severe fright. The fits occurred about every three weeks for the next four years. Since that time the attacks have been getting more frequent, although he has been under continual treatment. In the month previous to the beginning of the opium treatment he had twenty-seven attacks —seventeen day attacks and ten night attacks, all of the haut mal type. Patient put an opium May 25, 1893.

The following is a record of his attacks while taking the opium: May 25th, six attacks; June 10th, two attacks; June 11th, one attack, followed by a maniacal outbreak. Rectal injection of 30 grains of chloral hydrate and 60 grains of bromide of potassium, hypodermatic injection of $\frac{1}{100}$ grain hyoscyamine hydrobromatis, and ice cap to the head.

June 12th.—Patient rational.

July 18th.—Opium stopped and given instead bromide of potassium, 30 grains four times a day.

August 27th.—Two "fainting" spells.
October 24th.—Petit mal
October 25th.—Petit mal.
November 3d.—Petit mal.
December 2d.—Two attacks of petit mal.
January —No attacks. Patient left the hospital.

CASE VII.—J. N——, male, sixteen years of age, no family history. Has had fits since seventh year. Cause, severe fright. The form that the attacks take is variable, occasionally they are of procursive type, sometimes petit mal and sometimes very severe attacks of haut mal. In the month preceding the opium treatment he had thirty-eight fits. Mentally, patient is entirely demented. Opium stopped and bromides substituted July 25th.

The following is the record of attacks for the remainder of the year: August, four attacks; September, one attack; October, three attacks, all of petit mal type; November, five attacks; December, three attacks, one of the haut mal type. Patient transferred to the asylum.

CASE VIII.—E. S——, male, twenty three years of age. Negative family history. Has had fits since childhood. Attributable cause, fright. Mentally the patient is morose, stupid, wrathy, and scarcely ever speaks unless angered. In month previous to establishing the opium treatment he had twenty-four attacks. Opium stopped July 25th and bromides substituted. The following is the record: September, 1893, two attacks; October, two attacks; January, 1894, two attacks; February, one attack; March, three attacks.

This patient has undergone a remarkable mental change for the better, is now cheerful and bright and works continually about the ward.

CASE IX.—C. F——, male, twenty seven years of age. Negative family history. Has had fits since he was eighteen years of age. At first they occurred at night, but for some years past he has had both night and day attacks. He has about eight attacks a month, in each one of which more than an hour elapses before he recovers consciousness. Mentally the patient is deranged, and spends most of the time praying. He received the opium in the regular way and was put on bromides August 2, 1893. He suffered no attack up to October 1st, when he was transferred to the surgical ward that he might be operated on for a malignant growth of the cheek. Since then he has had a few light attacks. Mentally he is greatly improved.

CASE X.—A. S——, male, twenty-six years of age. Paternal uncle has epilepsy. This patient had convulsions when a child after an attack of scarlet fever. When ten years of age had his first severe fit. He has been under almost continual treatment in this country and Germany since his boyhood, but the attacks have become more frequent and severe. Sometimes he will have three or four attacks in a day and then will not have a repetition for a week. Most of the attacks are in the day. Mentally and physically the patient is in fairly good condition. Patient put on opium June 10th and stopped August 2d.

The record from that time is, August 6th, two "fainting" spells; November 28th, two attacks of petit mal; February 5, 1894, one haut mal; February 10th, petit mal; March 7th, petit mal.

In conclusion it gives me great pleasure to acknowledge the many valuable suggestions received from Dr. C. L. Dana relative to the prosecution of this trial, and to thank him for placing at my disposal the extensive material of his clinic at the New York Post Graduate Medical School.

To Dr. E D. Fisher my best thanks are due also for allowing me the privilege of his wards at the Alms House. The valuable and untiring aid rendered me by my successive house physicians, Drs. Hedges, Grandy, and Worth, at the Hospital for Nervous Diseases is gratefully acknowledged.

43 WEST THIRTY-NINTH STREET.

A RARE CASE OF SCLERO CORNEAL STAB—GREAT LOSS OF VITREOUS — COMPLETE COLLAPSE OF GLOBE — INTRA-OCULAR HEMORRHAGE — TREATMENT WITHOUT ANY PAIN—GLOBE SAVED.

BY DANIEL R. AMBROSE, M.D.,

NEW YORK.

THIS case is interesting not only from its rare character and result, but also from the novel, yet very simple, treatment. In his chapter on "Wounds and Injuries of the Sclerotic," Soelberg Wells says: "When the wound is very extensive and a large portion of the contents of the globe has escaped, and there is no hope of restoring any sight, it is better to excise the eyeball at once, more especially if it is to the patient a matter of great moment (as among the poorer classes) to be cured as soon as possible, and to be free from further inflammatory attacks." [1]

In a large hospital and dispensary practice, extending over a period of fifteen years, I have never seen an incised wound of the eye so deep, extensive, and apparently hopeless as the following:

M. W——, aged twenty nine, butcher, came to my office, Sunday afternoon, February 7, 1886, with his right eye covered with cloths, over which was tied a handkerchief. After removing these the lids were closed and sunken as in a case of extreme phthisis bulbi. After separating the lids the eyeball appeared not more than one fourth its normal size, so great was the collapse from an incised wound commencing on nasal side of sclera, apparently one-fourth of an inch from the limbus conjunctivalis, near the horizontal diameter, and extending forward and slightly upward to one eighth of an inch from the temporal limbus conjunctivalis, cutting through sclera, choroid, and retina, and extending through cornea, iris, ciliary processes, zonula, and splitting or displacing the lens, which in all probability escaped with the gush of the vitreous. The iris was divided throughout the entire extent of the corneal portion of the wound. There is intra-ocular hemorrhage, and very probably detachment of the retina. A portion of vitreous had lodged in the scleral portion of the wound, occupying about one fourth of its extent, which I did not disturb. The iris prolapsed through the entire length of the corneal portion of the wound, and with the convex surface of Daviel's spoon I gently pushed it back within the corneal margins. He is a strong, muscular man, but very pale and nervous from anxiety, and said that while in a stooping position gathering up the entrails of a hog, a drunken companion, who was scraping down an adjoining animal with a knife, recklessly thrust the point of the instrument upward into his eye, with the above result.

In consequence of the sudden and unexpected blow between the involuntary contractions of the lids, these escaped entirely and the eyeball received the whole force of the blow. My first thought was to close the scleral portion of the wound with a suture. My second thought was not to do so. Why? No one could surely predict firm union of the corneal margins in such an extensive wound within forty-eight hours. And in a strong man like this, in such a state of nervous depression, there must surely follow within forty-eight hours, and probably within twenty-four hours, a vigorous reaction, with a reformation of vitreous and aqueous humors, which, in rapidity and force, would cause an intra ocular pressure similar to that in glaucoma fulminans, which a so extensive corneal incision in almost the horizontal diameter, where little or no support could be obtained from the lids, and with but a weak adhesion, would hardly be able to resist; and if the corneal adhesion, which I hoped to obtain, should give way, all would be inevitably lost.

I told the patient that he might be prepared for total loss of sight in that eye, and that there was a strong probability that the wounded eye would have to be removed, but at the same time I hoped, with care and regular at-

[1] Page 214, Soelberg Wells.

tention to be able to save the eyeball. By leaving the scleral portion of the wound open as a safety-valve, and giving firm but comfortable support to the cornea with compress and bandage, I hoped to prevent a reprolapse of iris and obtain primary union of the corneal portion of the wound and save a globe which would disfigure but little, if any, and save him the annoyance and expense of an artificial eye every eighteen months or two years. So I carefully and gently cleansed the eye with soft cloths and lukewarm water, put in two drops of a four-grain solution of atropine, and repeated this four times at intervals of about five minutes, and then applied a firm but comfortable compress and bandage, and sent him home with an injunction to send for me if he had any pain.

The first layer of cotton in contact with the eye was saturated with glycerine. About 7 P.M. he sent a boy for medicine. I did not send anything, but went to his rooms in a tenement-house, where I found him sitting with a bright lamp directly in front of him, with a roomful of people, who were talking rather excitedly from the effects of stimulants. All, except his own family, were immediately directed to leave the room, and he was instructed to have the lamp behind him and to keep quiet. He said he did not have any pain, but only a slight sore feeling and feared it might get worse during the night, and therefore sent for medicine to have it ready in case of necessity. After he had been quiet about half an hour he said he felt quite comfortable, so I gave him nothing and did not disturb the bandage, and, after directions to sleep with his head and shoulders well raised, I left him.

February 8th.—Twenty-four hours after his first visit he returned to my office, a distance of nine blocks, and said he had passed a very comfortable night, and had not had the slightest pain or sore feeling since I left him. After cautioning him to keep his eyes closed I removed the dressing. The eyeball had filled out considerably, but not quite equal in size to the fellow-eye; the lids are natural, there not being the slightest appearance of inflammation at the margins. After gently washing the lids with a soft cloth and lukewarm water, and slightly pulling down the inner corner of lower lid and dropping a four-grain solution of atropine four times, about five minutes apart, into the eye, I reapplied compress and bandage as before.

February 9th.—Returned and says he has not had any pain, and rested quite comfortably the night before; dressing removed; the eyeball has filled out equal to its fellow, and the lids appear quite natural. Eye gently washed; atropine, compress and bandage as before.

February 10th.—Has had no pain, though the eye is now fuller and more prominent than its fellow, and margin of the upper lid is slightly red and swollen. After directing him to make no effort to open his eyes, I gently and slightly raised the upper lid and was much gratified to find thorough primary corneal union all along the line. The vitreous which had lodged in the scleral wound has entirely disappeared; treatment the same.

February 11th.—The upper lid is more swollen than yesterday, but he says he has not had the slightest pain; treatment the same.

February 12th.—The swelling of lids is more extensive than yesterday, and they bulge forward considerably, are red and glazed and have all the appearances of a severe panophthalmitis in full bloom, except the pain, which is entirely absent; treatment the same. For the last two days the cotton compress has been quite wet with water, but only a trace of muco-pus.

February 13th.—Has had no pain. Appearances the same as yesterday; treatment same.

February 14th.—Has had no pain. Appearances about the same as yesterday, except that the lids do not appear quite so tense, and there is a little more pus to be seen when the margins of the lids are separated; treatment the same. Without recording the monotonous daily details, from this time on there was a gradual subsidence of the inflammatory action, without any pain and without the slightest change in treatment. It was a noticeable feature of this case throughout the treatment that there was less suppuration than I had ever before seen in an inflammation of such a violent degree. Nothing occurred worthy of special note until February 28, 1886, when, the eye having much improved, the swelling and redness of the lids having entirely disappeared, but there being still a slight degree of conjunctivitis, with marked injection of the superficial and deep ciliary vessels extending all around the cornea, but most marked near the seat of the scleral wound, he attended church, which had not been warmed, at 7 A.M., while the thermometer, as reported by morning papers, was at ten degrees above zero. While at his devotions he felt a chill run through his body, and his eye felt as though something was in it; he said he thought a portion of the cotton compress had gotten into the eye. I removed the dressing, but there was nothing in the eye, and the symptom he described was caused by increase of conjunctivitis brought on by cold while at church. I then directed him to remain in his room until the weather became warmer, and there I gave him the same daily attention without the slightest change in treatment. This increase of conjunctivitis, with its accompanying symptom, as though something was in the eye, was relieved in forty-eight hours; but I confined him to his rooms and continued the same daily treatment for one week until the cold wave had passed and the weather had become milder.

March 15th.—He can distinguish a white shirt bosom, a white hat with a black band around it, and my hand at about three feet, but he cannot count fingers at any distance. As he had to return to work and would be daily exposed to a varied atmosphere, and also dust, and as the injection of the deep and superficial ciliary vessels continued, I thought it safer to continue the treatment at intervals of every second day until May 10, 1886, when the bandage was removed and the eye protected with a light pad of cotton, over which was placed a paste-board covered with black silk.

The small margin of the scleral wound, of one-sixteenth of an inch beyond the ciliary zone, healed much more quickly and kindly than that part running directly through the ciliary zone, which healed very slowly and was long marked by the injection of the superficial and deep ciliary vessels. The paste-board with dark silk and slight pad of cotton was, in consequence of his occupation and frequent exposure to variable temperature, continued until June 26, 1886, when all appearance of inflammation and irritation about the eye had entirely disappeared, and the ciliary vessels, both shallow and deep, had regained their normal condition, and there were neither perceptible bulging nor depression of the sclera, one of which is almost the invariable result of wounds extending through the ciliary zone. The scleral portion of the scar, which can be easily seen, measures six thirty-seconds of an inch from the limbus conjunctivalis. The direction of the line of the incision runs from a point on the nasal side of the sclera six thirty-seconds of an inch from the limbus, and about five degrees below the horizontal diameter, and extends to a point on the cornea one-eighth of an inch from the temporal limbus conjunctivalis and about five degrees above the horizontal diameter. There is anterior synechia to both lips of corneal incision throughout its entire length, except a small portion at the lower margin of the pupil about the size of the head of a small pin, which is perceptible when under the influence of atropine. The globe appears of full size and good shape, but the cornea is flattened.

During a large dispensary and hospital service extending over a period of more than fifteen years I have seen a great variety of injuries and deformities of the cornea, but have never before seen a case like this resulting from a wound, the cornea markedly flattened, yet apparently equal in all of its diameters to that of the uninjured eye.

Neither can I remember of ever having read of such a case. [Flattening of the cornea without any diminution of its diameters may, and often does, exist as the result of old age, and may be caused by glaucoma as the result of long and marked increase of the intra ocular pressure, which, while it causes the globe to approach the spherical shape, stretches the ciliary nerves which run between the sclerotic and choroid, and paralyzes them to a greater or less degree.]

The flattening of the cornea in this case is due to one, or both, of two causes: 1st. The oblique course of the knife through the ciliary region not only divided the ciliary muscle and ligament, but also some of the ciliary nerves, causing paralysis of the former. [Although the system of ciliary nerves are mainly derived from one (the ophthalmic) of the sensory branches of the fifth pair, it receives motor power, through the medium of the ciliary ganglion, by a branch derived from the third nerve.] 2d. The extensive anterior synechia along both lips of the corneal incision very probably exerts some influence in producing this flattened condition of the cornea. There is a slight depression without any discoloration along the line of the scleral portion of the scar. This reminds me of a ditch which has been filled up almost to the surface with the surface portion of the soil through which it had been dug in consequence of the long neglect of a lazy farmer.

What does it indicate? That union by retina, connective tissue, and conjunctiva has taken place; there being no direct adhesion of the edges of the sclera. Of what importance is that? Remember the last question, for under the head of Suggestions this very shallow ditch will be again alluded to and its importance will there be pointed out.

November 6, 1886.—He can distinguish my hand from one to three feet, but he cannot see fingers at any distance. The image of the hand, or other objects, is, after a few seconds, lost. It may be asked, Why not perform an iridectomy and give this man a larger pupil and more light in that eye? At first this may seem very plausible, but very probably there is detachment of the retina to a considerable extent (and it would be miraculous if there were not some degree of detachment of the retina after such a sudden evacuation of almost, if not quite, the entire contents of the vitreous chamber), and an iridectomy, at best, could give very slight, if any, improvement where there is detachment of the retina; while the risk of starting an irido-choroiditis by doing an iridectomy where there is such an extensive anterior synechia, and very probably degeneration of the iris, which might not only destroy the faint vision he now has but also cause atrophy of the globe, is considerable. Therefore, for the best interest of the patient I deem it wiser to let well enough alone.

Dr. J. F. Gray saw this patient with me during and at the termination of the treatment, June 16, 1888. It is now over two years and four months since the accident occurred, and there is not the slightest symptom of irritation in either eye. The tension is normal, being the same as that of the fellow eye. The horizontal diameter of the right, or injured cornea, from limbus to limbus is fourteen thirty-seconds of an inch, while the corresponding diameter of the left cornea is fifteen thirty seconds of an inch. The vertical diameter of the left cornea from limbus to limbus is fourteen thirty-seconds of an inch, and the vertical diameter of the right or injured cornea is also fourteen thirty seconds of an inch. Measurement of palpebral fissures directly over the centres of pupils, while patient is looking straight forward, shows the following results: When the measure approaches the left eye, as near as possible without contact, he can, after a few trials, control the involuntary contractions of the lids, and then, while looking straightforward, the fissure over the centre of the pupil is fourteen thirty-seconds of an inch; but after several trials, as with the left, the lids of the right, or injured eye, in spite of strong efforts to control them, will contract as the measure approaches, and during this contraction the palpebral fissure of the right, or injured eye, is eleven thirty-seconds of an inch—three thirty seconds of an inch less than that of the good eye. But when I wave my finger up and down several times commanding him to follow the finger with his eyes and look at nothing else, and then suddenly bring my finger to a rest on my right eyebrow, I can then approach his injured eye with the measure without any apparent contraction of the lids, and then the palpebral fissure of that eye is twelve thirty-seconds of an inch over the centre of the pupil—or only two thirty seconds of an inch less than that of the good eye. This temporary exercise of the eyes and mental diversion removed that nervousness shown a few moments before in the injured eye, and which had caused the contraction of the lids as the measure approached them, in spite of his efforts to control them. I remarked that the lids of the injured eye were not much nearer to each other than those of the good eye, to which his wife replied, "Oh! I didn't think anything of that, for I have always noticed that the lids of the right eye were a little contracted;" and the patient said, "That is so, the lids of the wounded eye have been contracted almost as long as I can remember." According to these statements the result is better than I at first supposed. He has perception of shadows at two feet. There is a white film occupying the space of the small pupil.

October 25, 1890.—It is now over four years and eight months since the accident occurred, and the eye remains in the same condition as noted June 16, 1888.

November 26, 1893.—It is now seven years and nine months since the accident occurred, and his wife says, when he remains sober his eye looks as well as it did June 16, 1888.

In this case no antiseptic, except cotton saturated with glycerine as an external dressing, was used. Several years ago I obtained primary union in cases not favored with good hygienic surroundings where the flesh had not only been torn, but dragged from its attachment by machinery and the glancing force of some instrument, by gently cleansing and carefully adjusting the related parts and dressing the wound with cotton saturated with glycerine and the patient's blood.

Under what more unpropitious circumstances can it be imagined that an eye will ever be operated on than existed in the above case, which was cut in the roughest manner possible, with a coarse and filthy knife, and almost directly through the horizontal diameter of the cornea, where the least support could be obtained from the lids, dividing it into two equal parts; and in the foul, moist, and comparatively warm atmosphere of a slaughter-house for hogs, reputed the most filthy of all animals, whence he had to go over half a mile—twelve and a half blocks—before his eye was cleansed and dressed.

There was no suppuration within the eye nor in the margins of the wound. The conjunctiva was the only tissue from which pus could be seen to issue, and it was markedly less than I had ever before seen in a case of so violent reaction, and this yielded in due time to atropine and unadorned cleanliness. And he did not have pain enough throughout the whole time of treatment to deprive him of one moment's sleep. The mouth of the scleral wound was daily exposed to pus from the conjunctiva for about two weeks, but this gave me no anxiety after I saw firm corneal union had taken place, because a full and boiling over capsule effectually prevented the entrance and accumulation of any foreign liquid.

The earnest attention of the ophthalmic surgeon is requested to the last sentence above, for in the class of cases to which I believe much good may be done by the timely use of the operation which will be described further on, there will always be some degree of conjunctival suppuration, and however much he may be impressed with its utility in relieving intra-ocular tension, and in promoting free circulation through the eye, and thereby preserving its nutrition, he may still be deterred from giving his patient the benefit of it for fear that the con-

junctival pus might enter the scleral incision and accumulate within the eye, and more than counteract all the benefit that might otherwise be derived from the operation. My chief anxiety, therefore, in this case, was that the scleral opening might unite before the inflammatory reaction could be checked, or had spent its force, and in consequence of its speedy union the circulation through the globe might become obstructed, and its nutrition, as well as that of the cornea, become impaired, and thereby defeat the purpose for which I had intentionally left the scleral portion of the incision open.

The favorable features of this case may be fairly attributed to simple cleanliness, firm and comfortable support to the cornea, atropine, and more than all else, to the continued relief of intra-ocular pressure until the inflammatory reaction had spent its force. The intra-ocular pressure was kept continually relieved by keeping the scleral portion of the wound continually open as a safety-valve, free circulation through the globe being thereby permitted, and its nutrition, as well as that of the cornea, preserved, and suppuration within the eye prevented, and lessened to a considerable degree from the conjunctiva. It may be supposed that these happy results were due to the age and vigor of the patient and to an unusual vitality of the tissues of his eye. But to such an hypothesis I would reply that the best results I have had after operations for cataract, or seen in the practice of others, have been in elderly and moderately emaciated people who did not seem to have vigor and vitality enough to get up a forceful reaction; while the worst results that I have witnessed have been in stout and vigorous-looking people. It should, however, be borne in mind that an opposite extreme may exist where the vitality is so low and the reparative lymph so deteriorated that union of the corneal incision after extraction may not take place, and then may follow sloughing of the cornea, panophthalmitis, and atrophy of the globe, in spite of all that can be done.

For many years I have watched with much interest the results of cataract extraction, in the practice of others as well as my own, and have seen in several cases, after the most skilful extraction by different operators and the most careful after-treatment, the eyelids become swollen, red, and glazed, with much pain in the globe and radiating along the course of the supra-trochlear, infra-trochlear, nasal, and temporo-malar nerves; and in spite of the careful use of all known remedies the patient would pass sleepless nights and wearisome days, and the sight, which was obtained immediately after the operation, and which so cheered the despondent mind, gradually, and sometimes rapidly, become dimmed until no object could be distinguished, and his hopes sink away never to return. I do not know anything, except the dying, which has caused me more melancholy feelings than the watching of these unfortunate cases.

Some years ago it occurred to me that something beyond the routine treatment—some secondary operation which would relieve tension, and keep it relieved until the inflammatory reaction had been checked, or had spent its force—should be tried early in these violent cases; but operative procedures, except paracentesis of the cornea, in the acute stages of such cases, have been objected to by some of the most eminent ophthalmic surgeons, and countenanced by none that I am aware of, on the ground of increased irritation which would inevitably follow. This objection is perfectly valid and well taken so far as the old and long used method of relieving tension—by paracentesis of the cornea—is concerned.

For, although by the use of cocaine complete anæsthesia of the conjunctiva and cornea may be obtained, and the former rendered insensible to the grasp of the forceps, and the latter to the cut of the knife, the iris is but little, if at all, affected by it; and although an expert surgeon may avoid tearing or pricking the iris he cannot prevent it bulging forward when the aqueous escapes. And this slight displacement, and possibly rubbing against the knife of so sensitive a tissue as the inflamed iris, must cause some degree of irritation. However, if the relief of tension temporarily obtained by paracentesis of the cornea could be safely made continuous at the surgeon's will, without the necessity of repetition, it might in a great measure compensate for the irritation produced by it. But, unfortunately, there is no way at present known by which that desirable result can be safely accomplished. The corneal incision will primarily unite within twenty-four or forty-eight hours; the inflammatory process of the iris and choroid is not checked; the aqueous and vitreous humors, which are incompressible substances, rapidly reform; the capsule, if possible, is still further distended until it has perhaps lost all of its resiliency, and this factor in the promotion of the intra ocular circulation is lost; the circulation becomes obstructed and consequently the nutrition becomes impaired, and then follows the formation of pus within the eye. Leeches, ice-cloths, warm douches, and other remedies, have for many years been used to check this inflammation, and when it is of a mild nature and of but moderate force are sufficient to subdue it. But I have seen several cases under the care of different surgeons which, after the timely and assiduous application of the usual remedies, were but slightly, if at all, relieved by them; the inflammation continued until suppuration within the eye occurred; the sight became greatly impaired; nay, totally lost. To meet and prevent such emergencies I would suggest sclerotomy before any destruction of tissue had taken place, if possible. It is not here claimed that sclerotomy is a new operation, for, on the contrary, it is quite ancient; but the method, purpose, and regard for neighboring parts, as will be further on described, I have never seen nor even heard suggested.

Under the head of "Treatment of Glaucoma," Stellwag says: "The paracentesis of the sclera, moreover, in connection with the emptying of a portion of the vitreous, has been recommended for a long time as a means of lessening the hardness of the globe (Mackenzie). Since, however, the technical performance of the operation was not adapted to produce a permanent relaxation of the sclerotic, it could only obtain transient, and therefore unsatisfactory results." Its union with the iridenkleisis (Critchett, Coccius) has theoretically very much to be said for itself, but is to be avoided on account of favoring cystoid cicatrices, and subsequent threatening irritation. The proposal to draw out the iris very much in iridectomy, in order to rupture the zonula, and thus to establish a connection between the vitreous and aqueous humors (Coccius), should find few friends, in consideration of the dangers which can accrue to the nutrition of the lens, and even of the entire globe, from a partial rupture of the ciliary body."[1]

From the above it may be seen that, in addition to the fact that the operator "could only obtain transient, and therefore unsatisfactory results" for one purpose for which the paracentesis of the sclera had been employed, there was also another important cause why the operation had been followed by not only unsatisfactory results, but also even worse, by its "favoring cystoid cicatrices and subsequent threatening irritation," and "in consideration of the dangers which can accrue to the nutrition of the lens, and even of the entire globe, from a partial rupture of the ciliary body," viz., that the paracentesis of the sclera had been done through the ciliary zone.

Suggestion 1—Method of Operating.—The patient having been placed on his back and anæsthetized, the surgeon, with fixation-forceps, grasps a fold of conjunctiva near the cornea, midway between the external and inferior recti muscles, and gently turns the eye downward and slightly outward. An assistant raises the upper lid with his finger. A thin Graefe knife, well sharpened and thoroughly cleansed, and with its cutting edge directed toward the posterior extremity of the eye, and its sides parallel with the longitudinal axis of the globe, so as to guard as much as possible against cutting any of the ciliary nerves, is inserted in the point midway

[1] Stellwag: Fourth edition, p. 318.

between the superior and internal recti muscles and five thirty seconds of an inch from the limbus conjunctivalis, and passed directly through all the coats to the vitreous, the blade being pushed inward only far enough for its point to pass through the retina, lest damage be done to the vitreous, when the incision is extended backward six thirty seconds of an inch. The length of the scar in the above case from the limbus conjunctivalis backward on the sclera is six thirty-seconds of an inch, and the posterior two thirty seconds of an inch of the incision healed very much more rapidly and kindly than the anterior four thirty seconds of an inch of the scleral portion of the wound did; and this fact indicates that in the horizontal diameter four thirty seconds of an inch from the limbus backward cover all those sublime structures lying within the ciliary zone, the wounding of which by accident or design has always disappointed the hopes of the surgeon and terminated so disastrously to the patient.

Argument.—Gray says: "The larger processes are each about one-tenth of an inch in length and hemispherical in shape, their periphery being attached to the ciliary ligament and continuous with the layers of the choroid; the opposite margin is free and rests upon the circumference of the lens. . . . The ciliary muscle . . . forms a . . . circular band, about one-eighth of an inch broad, on the outer surface of the fore part of the choroid. It consists of two sets of fibres, radiating and circular. The former . . . arise at the point of junction of the cornea and sclerotic, and, passing backward, are attached to the choroid opposite to the ciliary processes. The circular fibres are internal to the radiating, . . . and have a circular course around the insertion of the iris."[1] Of the sclerotic, Gray says: "In front the sclerotic is continuous with the cornea by direct continuity of tissue, but the opaque sclerotic overlaps the cornea rather more on its outer than on its inner surface." Of the cornea, Gray says: "It is not quite circular, being a little broader in the transverse than in the vertical direction, in consequence of the sclerotic overlapping the margin above and below."[2]

From this eminent authority it will be seen that one-eighth of an inch from the corneo-sclerotic junction extending backward covers those very important parts lying within the ciliary zone; and from the last quotation that the cornea is "a little broader in the transverse than in the vertical direction, in consequence of the sclerotic overlapping its margin above and below." Gray says the eyeball in its antero posterior diameter is "about nine-tenths of an inch," which, reduced, is equal to $\frac{28\frac{4}{6}}{32}$ of an inch. The average height of the normal cornea from limbus to apex, measured in the horizontal diameter, from thirty to forty years of age, is, so far as I have examined, about $\frac{2\frac{4}{6}}{32}$ of an inch; while at about sixty years of age it is about $\frac{2\frac{5}{6}}{32}$ of an inch. In the following estimate I will calculate from the greater height because the shortening of the eyeball in old age is due, so far as is at present known, solely to the flattening of the cornea.

Therefore $\frac{28\frac{4}{6}}{32} - \frac{2\frac{4}{6}}{32} = \frac{26}{32}$ of an inch, which represents the average length of the eyeball of the adult from the corneo scleral junction to its posterior end. Now from $\frac{26}{32}$ take $\frac{5}{32}$ of an inch in the location proposed for this operation, and there will remain $\frac{21}{32}$ of an inch; at the point of five thirty-seconds of an inch from the limbus backward, the scleral incision begins and extends backward six thirty-seconds of an inch and then there will remain fifteen thirty seconds of an inch of the posterior part of the eyeball, or more than half of the twenty-six thirty seconds of an inch, which represents the average length of the eyeball from the corneo-scleral junction to its posterior extremity; and therefore the posterior extremity of the incision will be above the equatorial diameter of the vitreous chamber when the patient is on his back. Under no circumstances should the knife be passed into the vitreous chamber at a point less than five thirty-seconds of an inch from the limbus conjunctivalis, except for the removal of a foreign body.

The incision made as above described, will not mutilate the iris, ciliary muscle, ligament, processes, or zonula, all of which should be carefully avoided.

In the location above described the incision, when the patient is lying on his back, is above the equatorial diameter of the vitreous chamber; and when lying on the side of the operated eye, as, when not otherwise directed patients instinctively and almost invariably do, the incision will be above the vertical diameter; and when in the erect position it will be above the horizontal diameter. In either of these positions which the patient is most likely to assume, and to which by special instructions he should be confined during treatment, the opening is always above the corresponding diameter of the vitreous chamber, and excessive leakage cannot occur even should the vitreous have degenerated to a liquid condition. While at the same time the open incision permits sufficient leakage of the constantly forming serous vitreous, caused by the inflammation, to prevent increase of intra-ocular pressure, and thereby not only preserves the resiliency of the capsule, but also permits free circulation through the globe and preserves its nutrition as well as that of the cornea until the inflammatory action is checked, or has spent its force. The scleral margins will not unite directly, and when treated by compress and bandage, as further on directed, the opening through all the coats will remain slightly ajar, and prevent its closing too soon by retina, connective tissue, and conjunctiva. Should this open suggestion excite the amazement of the reader he may restrain his astonishment and bear in mind that the location designated for the incision is, from its complete covering by the upper lid under ordinary circumstances, but more especially when the eye is turned upward, as patients involuntarily do when there is much inflammation, almost if not quite as secure from the atmosphere as though it were a subcutaneous tenotomy. As soon as the incision is completed, carefully remove forceps without making any pressure on the globe, drop in atropine on inside of lower lid, cleanse and close the lids, and apply a clean soft cloth saturated with vaseline or pure glycerine, and carefully apply compress of clean cotton by filling up the inequalities about the orbit until the cotton is well raised above the supraorbital ridge, and over this apply firmly, but comfortably, a flannel bandage one and a half inch wide and four yards long, carrying a layer of bandage over the operated eye four times, and pin it carefully that it will not slip. When compress and bandage are carefully applied, they are comfortable and almost as firm as a plaster-of-Paris dressing, and will remain so for twenty-four hours, when they should be removed, the eye gently bathed with soft cloth and lukewarm water, and fresh dressings applied. The patient should be directed to lie with head and shoulders elevated at an angle of thirty or forty degrees.

The advantages claimed for this operation, when performed within the prescribed limits, purposes, and after-treatment, are: 1. Quick relief of pain. 2. Instead of increasing irritation it will relieve that which already exists. 3. It will relax tension and permit free circulation through the globe. 4. It will preserve the nutrition of the globe and cornea more than any other remedy at present known.

From the history and result of this case I believe three valuable lessons may be learned.

1. That in extensive incised wounds of the eyeball, even when the sclerotic is involved, and when a "large portion of the contents of the globe has escaped and there is no hope of restoring any sight," even "among the poorer classes," the surgeon should not at once jump to the conclusion that the destructive operation of enuclea-

[1] Gray: Eleventh edition, pp. 810–812. [2] Ibid., pp. 806, 807.

tion of the eyeball is inevitable, but he should by measures, not necessarily drugs, reasonably adapted to the circumstances of the case, endeavor to at least preserve the globe. When the globe is preserved without any irritation, although the sight may be lost, it is far more comfortable and economical for the poor man than an artificial eye, which has to be removed, cleansed, and reinserted every night and morning, and renewed every eighteen months or two years; to say nothing of the irritation often caused by an improperly fitted artificial eye and consequent atrophy of conjunctiva. Unless there be ciliary irritation long after the inflammation of the globe has disappeared, the danger of sympathetic ophthalmia, according to my experience, has been largely exaggerated.

2. That the surgeon should not waste time in a severe case, except it be syphilitic, in the delusive effort to cure suppuration in the eye with drugs, and especially if the patient be one of "the poorer classes," to whom it is a matter of great moment to be cured as soon as possible," and with the greatest amount of preservation of his natural organ.

3. That if so good a result can be obtained in a case with the cornea split into two equal parts, and under such unfavorable conditions, by the aid of a sclerotic safety-valve, it is reasonable to hope for far better results under more propitious circumstances where the surgeon may perform a timely sclerotomy in a location where neither the cornea nor any of those important parts lying within the ciliary zone can be injured.

Suggestion 2.—To mention sclerotomy at any part where the instrument must enter the vitreous chamber as a probable cure for glaucoma in the face of its past history, and of what some of the most eminent men in the medical world have written about it, and especially at an age when there is an operation for glaucoma which has been in unrivalled use for about a quarter of a century, and which has in many cases given very fair results, may appear like a reckless suggestion. In presenting its claims to the profession it will therefore be needful to compare its advantages and disadvantages with those of the operation now in use, viz., the broad paracentesis of the sclera through its most anterior zone into the aqueous chamber, combined with an iridectomy. The advantages of the last-mentioned operation are: 1. That the instrument pierces only the anterior scleral zone and does not enter the vitreous chamber. 2. When early and skilfully performed it has in many cases given very fair results, that is, complete relief of pain and a fair amount of vision. Its disadvantages are: 1. That it necessitates the destruction of a large portion—about one-fifth—of the iris; not because the destruction of this tissue is essential to the cure of the disease, but because of the danger of its prolapse if not destroyed, and the difficulty of restoring it when prolapsed, and its great liability to lead to dangerous irritation. 2. Its location is not only favorable for the prolapse of the iris when a large portion of it is not excised, but even after such excision the margins of the wounded iris are very liable to be caught in the lips of the scleral incision and lead to dangerous and irreparable irritation. 3. The excision of the segment of iris, as is required in its performance, close up to its ciliary attachment, may, in the hands of an inexpert operator, cause a rupture of the zonula and endanger the safety of the globe. 4. Cataract may be caused by the point of the instrument piercing the capsule of the lens during the performance of the operation, and this accident is quite probable in the hands of an inexpert operator. 5. The more or less dazzling caused by the greater volume of light admitted through the coloboma formed by the iridectomy. 6. The increased danger of hemorrhage, in the hemorrhagic diathesis, from the cutting of so many blood vessels in the excision of the segment of iris. 7. The increased risk of sympathetic glaucoma in the fellow-eye as the early result, upon an already existing predisposition, of the shock from the wounding of so many ciliary nerves in making the broad incision through the anterior scleral zone and the excision of so large a portion of iris; this increased irritation in a weakened nervous system, conveyed through the ciliary branches derived from the ophthalmic division of the fifth pair to the ciliary ganglion, and thence by its sympathetic root to the cavernous plexus, and thence through "the filaments prolonged on to the anterior communicating artery form a small ganglion, the ganglion of Ribes, which serves, as mentioned above, to connect the sympathetic nerves of the right and left sides"[1] to the other eye, causing or increasing the secretion of serous vitreous and an increase of intra-ocular tension. 8. "It also exceptionally occurs that directly after the iridectomy the resistance of the globe increases markedly, the globe even becomes of a stony hardness. Such cases always run an unfavorable course, according to previous experience" (Liebreich[2]). 9. "In cases of glaucomatous degeneration, iridectomy is apt to make the disease worse, as it usually causes extensive intra-ocular hemorrhage."[3]

The advantages of sclerotomy into the vitreous chamber, when performed in the location and within the limits above prescribed for the relief of intra ocular tension in panophthalmitis or glaucoma are: 1. There is no destruction of iris or of any other tissue. 2. It is performed in a position where the iris cannot prolapse and cannot be caught between the lips of the scleral incision, and therefore no subsequent irritation can arise from that source. 3. There being no iridectomy in this operation there is not the slightest danger, with the most ordinary care, of disturbing the continuity of the zonula or ciliary processes. 4. With ordinary care there is no danger of causing cataract by the point of the instrument piercing the capsule of the lens. 5. There can be no dazzling from an increased volume of light because there will be no coloboma of iris. 6. The danger from hemorrhage, in a hemorrhagic diathesis, will be less because there is no destruction of tissue and a much smaller number of blood-vessels divided. 7. There will be much less risk of sympathetic glaucoma in the fellow eye because there will be much less injury done to the ciliary nerves; not more than one, and probably none, of these nerves will be wounded if the operator is careful to make the incision in a straight line, parallel with the longitudinal axis of the globe. 8. The firm compress and bandage, as already prescribed for use after the operation for the relief of intra-ocular tension in panophthalmitis, will help to keep the incision open and to promptly afford relief to any increase of tension which may be caused by hemorrhage, and will be an aid in checking hemorrhage in glaucomatous degeneration, which is so liable to be made worse by an iridectomy.

The chief disadvantages of sclerotomy into the vitreous chamber are two long standing objections which have disappointed the hopes and baffled the skilful efforts of some of the most eminent surgeons throughout the civilized world for over a quarter of a century, viz., 1. "Since, however, the technical performance of the operation was not adapted to produce a permanent relaxation of the sclerotic, it could only obtain transient and therefore unsatisfactory results:"[4] 2. "Its union with the iridenkleisis (Critchett, Coccius) has theoretically very much to be said for itself, but is to be avoided on account of favoring cystoid cicatrices, and subsequent threatening irritation."[4]

The result of the foregoing case, upon which these suggestions are based, clearly proves that these last two objections can be avoided; for there is not the slightest show of a cystoid cicatrix, and the very shallow ditch along the line of the scleral incision, which has been covered over and nearly filled to the surface by a normal conjunctiva—the surface soil through which it had been dug—proves without a doubt that there is permanent relaxation of the sclerotic. I believe these last two

[1] Gray: Eleventh edition, p. 789.
[2] Stellwag: Fourth edition, p. 323. [3] Ibid., p. 324. [4] Ibid., p. 318.

objections may now be excluded from the list of disadvantages of sclerotomy into the vitreous chamber; and that sclerotomy into the vitreous chamber may become as successful as laparotomy is to day, when the operation is confined to the limits and purposes herein prescribed.

IS PLEURISY RHEUMATIC?

By W. N. MacArtney, M.D.,

Fort Covington, N. Y.

Some three years ago the writer, owing to the frequent occurrence of pleurisy as a complication in a series of cases of acute articular rheumatism, had his attention drawn to the latter disease as a possible important factor in the causation of pleuritic inflammations. Consultation of the authorities at my disposal led me to the following conclusions: That the occurrence of pleurisy with rheumatism is recognized; that mention is made by most writers of rheumatism as a possible cause of pleurisy, but that the association of rheumatism and pleurisy is no more obvious to these writers than the association of pyæmia, alcoholism, nephritis, or the exanthemata. This did not seem to tally with my own experience, and further observations seemed necessary to establish the relationship of the two diseases in my own mind. Since then a record of cases of pleurisy, as they occurred in the regular routine of my private practice, has been kept, and I was led to believe that either rheumatism deserves a more important place in the etiology of pleurisies or I have been misled by a rather remarkable series of cases of this disease. For convenience I have tabulated these cases.

The list comprises in all forty-four cases. They occurred in the order here shown. All were well-marked cases. Every case of a mild character was excluded, as was also every case where the diagnosis was doubtful. Several cases of empyema were excluded for several reasons. These cases of empyema were proven to be such at the first visit; they were surgical cases, they were not amenable to the treatment employed in the cases of pleurisy proper, and moreover, they had no special bearing on the question involved. I may state here that the list, however, includes several cases where empyema was, from the presence of recurring chills, sweats, etc., suspected, but happily did not "realize." Special care was taken also to exclude all cases of hydrothorax and pleurodynia, no case being recorded which did not present well-marked physical signs of pleuritic inflammation, and no case being omitted except as above mentioned.

The ages range from less than two to eighty-two years. There were twenty six females and eighteen males. Many of these cases were first seen when the disease was well established, and of necessity the previous duration of the disease is given approximately, there being no guide other than the history obtained from the patient or the patient's friends. The average duration under treatment was a trifle over six days. In twelve of these cases the fluid accumulation was sufficiently extensive to displace the apex beat well to the opposite side. It is interesting to observe that, in contrast with the writer's previous experience, in no case did empyema occur (though Loomis observes that when pleurisy occurs in children, as a sequel to the exanthemata, pus is usually formed); that no cases were fatal; and that in no instance was aspiration necessary, though in two instances a hypodermic syringeful of the fluid (about twenty minims) was withdrawn solely for the purpose of microscopical examination. Otherwise no operative procedure of any sort was performed.

In all these cases but one general plan of treatment was carried out—the anti-rheumatic. This in the main consisted in the administration of salicylate of soda in full doses, and at short intervals, until the characteristic head symptoms were produced, and this effect was, when possible, maintained. In no case did collapse occur; but in two cases—both of them children—slight delirium was observed from pushing the salicylate too far. The alkalies and other anti rheumatics were used freely when indicated, tonics when required, and in general the treatment was such as I adopt in inflammatory rheumatism.

List of Cases.

Number.	Name.	Age.	Sex.	Extent of Effusion.	Supposed Duration Prior to First Visit.	Subsequent Duration and until Recovery.	Complications.	Remarks.

The results were, to me at least, highly satisfactory. In some instances the fluid disappeared almost entirely in twenty-four hours, even when the pleural cavity was nearly full. In one case (No. 39), lasting twenty-three days under treatment, the salicylates could not be borne

for any length of time. When the stomach would tolerate it the fluid subsided rapidly. As soon as the remedy had to be omitted it reaccumulated. This occurred several times during the first week or ten days, and furnishes strong proof of the efficacy of the salicylate in promoting absorption of the pleural exudate. Eventually, on account of the irritable condition of the stomach, it was abandoned, and salol with antipyrin substituted. This case has still some dulness at the base of the pleural cavity, not due, however, to the presence of fluid but to pleuritic thickening. The same condition is observed to a slight degree in two other cases of like character.

No claim is made that salicylate of soda is a specific in pleurisy with effusion, or in dry pleurisies. But that it will reduce the effusion, abate the cough, relieve the pain, and cure the patient more rapidly and effectually than any other remedy with which I am acquainted, this much I am certain of.

Neither is there any claim for priority in the use of this remedy, as I am well aware that Germain Sée, Aufrecht, and many others have advocated its use. But some three years ago, without the knowledge that it was used by others in this disease, I began the use of this remedy in pleurisies of rheumatic origin, and was so well pleased with the results that I had no hesitation in extending its use to cases which were not obviously rheumatic, using it since then persistently in all cases which were non-purulent. It would be, of course, as absurd to rely on the use of this remedy in empyema as to treat a suppurative knee-joint on the alkaline plan.

In cases Nos. 24 and 33 two distinct attacks of pleurisy occurred, with an interval of about one year. The patient was on anti-syphilitic treatment, and when the effusion took place the only modification of the treatment was the addition of full doses of the salicylate.

Nine cases occurred in connection with phthisis. In no case was a pleurisy the starting-point of a phthisis. Two cases occurred during convalescence from measles—one as a complication of scarlet fever; five followed or were coincident with the various forms of pneumonia, but in these cases the pneumonia played a secondary part where the two were present at the same time.

Are the results noted due solely to chance—to the happy use of a so-called specific? Or is the secret of success in these cases due to the recognition of the underlying factor—the rheumatic diathesis?

Pleurisy is not a fatal disease. Under any ordinary plan of treatment the vast majority of cases eventually recover. A few develop extensive pleuritic adhesions and thickening, some empyemas, and still others run into phthisis or interstitial pneumonia. As previously noted, three of the cases cited developed pleuritic thickening. As these cases were severe, as the disease had existed in each instance for some length of time before treatment was instituted, and as they were the kind of cases which, according to my previous experience, usually developed pus, I have reason to be satisfied that they recovered with no further trouble than the pleural thickening.

Is pleurisy rheumatic in its origin? Practically I have found that the average run of cases is purely rheumatic.

Loomis says "the etiology of acute pleurisy is sometimes very obscure." He states that it occurs in connection with injuries, pyæmia, the exanthematous fevers, acute and chronic alcoholism, acute rheumatism, Bright's disease, pneumonia, etc. Flint, giving practically the same causes, mentions that "it is developed occasionally in connection with acute articular rheumatism." Wilson, in "Pepper's Practice of Medicine," makes no mention of it as a cause of dry pleurisy, and mentions it merely as occasionally associated with pleurisy with effusion. Other writers lay especial stress on tuberculosis as the usual causative factor. Still others advocate the microbic origin. In fact, the list of possible causes is so long and so indefinite as to resemble in its length and uncertainty, at least, a chapter on the etiology of acute rheumatism.

If these writers represent the profession as a whole, if this is the generally accepted view of the causation of pleurisy, then I am compelled to take issue with them. I believe that the most prominent cause of pleurisy is rheumatism. I wish it distinctly understood that I do not hold that every case of pleurisy is rheumatic. That the suppurative pleurisies are due to infection by the diplococcus of Fraenkel, by streptococci, or by staphylococci is admitted. That simple pleurisies may arise in other ways is conceded. But that the commonest cause is rheumatism I am convinced—rheumatism pure and simple, rheumatism as an intercurrent affection, or rheumatism engrafted upon some chronic tubercular or other previously existing disease.

In reviewing the reasons which led me to arrive at this conclusion I find that they are numerous.

To properly appreciate them a careful comparison of the two diseases is necessary. The reader will bear in mind that it is but fair to contrast the pleuritic inflammation with the purely synovial inflammation in joint rheumatism. The pleura is a serous membrane, a gliding joint if you will, or an enlarged bursa, between the lung and the chest-wall. Its function is to allow full movement and to prevent friction, and it is lubricated with a serous fluid. In other words, it is a modified joint, not between two bones, but between the lung and the thoracic wall. Gray says that the synovial membrane "resembles the serous membranes in structure, but differs in the nature of its secretion, which is thick, viscid, and glairy." This is a difference in degree, not in kind. We do not use successfully the same lubricant for a lumber-wagon and for the delicate mechanism of a watch, yet the principle is identical. That the joint surface and the pleural surface, or perhaps, more properly, the joint cavity and the pleural cavity, are similar in structure, in secretion, in function, and in the character of their inflammatory affections, is evident. That slight variations are found is but to be expected.

Pleurisy may be acute, subacute, or chronic. So also a rheumatic joint. Pleurisy may result in the formation of fibrin, serum and fibrin, serum, fibrin and pus, or new connective tissue. It may be dry or wet, suppurative or adhesive. Compare this with the changes which occur in the synovial membrane of the knee-joint, for instance. Have we not all seen a "dry" rheumatic joint with distinct crepitus like that of pleurisy; joints with effusion from rheumatism; joints with fibrous anchylosis from this cause, and, though more rarely, abscess in the knee-joint from a neglected rheumatic effusion which became infected with pyogenic germs?

A comparison of the statements of the majority of our writers in regard to the etiology of pericarditis and of pleurisy might be instructive. Wilson, in "Pepper's Practice," states that "by far the most important cause of pericarditis is acute articular rheumatism," yet he merely gives passing mention of rheumatism as a possible cause of pleurisy. Other writers take practically the same stand. Yet in what essential does the one closed sac of serous membrane differ from the other either in structure or in function? Why should rheumatism patronize the one exclusively and boycott the other? Surely such partiality is unfair! Let rheumatism attack something of its size, and not pitch solely into the smaller neighbor.

An analysis of the forty-four cases in the list throws some light on the subject. Sixteen cases occurred in connection with acute rheumatic attacks, one with tonsillitis of a rheumatic nature (?), and one with severe rheumatoid arthritis. This is in itself a strong argument. A personal acquaintance with these cases and the members of their immediate families shows something which does not appear from the list of cases—that the rheumatic diathesis played an important part in many of the cases which could not be classed as directly due to, or associated with, distinct rheumatic attacks in other

parts of the body. These cases are, of course, not classed as rheumatic in the list given above.

Eight of the cases were evidently directly due to exposure to wet and cold, such exposure as might readily induce an attack of inflammatory rheumatism.

Nine cases occurred in connection with phthisis. Was the pleurisy merely a part of the phthisical process already established, or was it an intercurrent affection? The patients almost invariably laid the pleuritic process to exposure to cold. This of course is not the best of evidence. They got well with remarkable rapidity on anti-rheumatic treatment. Rheumatism "goes to the weak spot"—in this case to the serous investment of the lung. The pleurisy was readily cured. The phthisical process persisted. It is reasonable to suppose that these pleurisies were non tubercular, but due to rheumatic attacks during the course of a chronic phthisis.

A few years ago, while engaged in surgical work exclusively, I treated numerous cases of synovitis of the knee-joint with effusion, due to injury, by means of plaster-of-Paris splints and the usual surgical procedures. Since then I have learned that there is another aspect of these cases, that a man who sprained his knee severely did not necessarily get an effusion into the joint; but, given a sprained knee and a "touch" of rheumatism, and you would be very apt to find it. So with pleurisy occurring in the case of a man who breaks a rib, in the syphilitic or in the tubercular subject, there may be more than one element at work.

Looking at it in this light, the necessity for fine points of differentiation between pleurodynia—the old-fashioned false pleurisy—and pleurisy proper is not so apparent. Purely from a practical stand-point it matters little whether the rheumatism is in the chest-wall, in the costal pleura lining the same, or in the pulmonary pleura immediately in contact with the latter. In a case of articular rheumatism we do not inquire so particularly as to whether the external parts only are involved, or whether the synovial membrane is also inflamed. There are few cases of pleurisy which do not on careful examination show strong evidences of pleurodynia or muscular rheumatism in the chest-wall, in addition to the signs of fluid effusion, the pain from pleuritic irritation, and the other classical symptoms of a full-fledged pleurisy. When we have a rheumatic joint do we treat the synovial membrane or the capsular ligament? Do we not rather treat the rheumatism as a whole, and the local lesions when indications call for it.

A disease so widespread as rheumatism, a disease which is acknowledged to be capable of affecting almost any portion of the anatomy, is fully capable of producing pleurisy, and it only remains for a sufficient number of careful observations, made with the end in view of settling this point, to establish the truth of this matter.

It may be added here that I find it not uncommon for a moderate pleural effusion occurring during the course of an inflammatory rheumatism to be overlooked. Cough and dyspnœa may be absent, and the pain in the side is easily accounted for. That it is a more common complication than is usually considered I am fully convinced.

This list of cases attests the value of the salicylates in promoting absorption of pleural exudates. Compare and contrast this general plan of treatment with that advocated by Loomis, who gives opium the most prominent place; with Flint, who advises bloodletting, opium, and aconite; with Pepper, who says that the "treatment is symptomatic;" with the blisterers, the tappers, and the "vis medicatrix" nihilists.

Can it be that we have something yet to learn in regard to this disease beyond the best way to keep an aspirator valve in perfect order, to sterilize a trocar, or to improve on Estlander's operation of thoracoplasty? Must we, on the other hand, go back to blind empiricism and give salicylate of soda because it is "good" for pleurisy, or antipyrin because it "absorbs" the effusion? Or shall we bear in mind the diathesis, the underlying condition, the predisposing cause, the etiological factor?

A theory of some sort is better than empiricism. Let this stand or fall as it deserves.

NEPHRITIS OF PREGNANCY AND ITS SEQUELÆ.

By EDWARD NICHOLAS LIELL, M.D.,

NEW YORK.

LECTURER IN GYNÆCOLOGY, NEW YORK POLYCLINIC.

In proportion as our knowledge of the nature of disease and the action of remedies increases, the practice of medicine becomes more rational and its basis more sound.

Though aware of the dangers not infrequently attending the nephritis of pregnancy, especially so in relation to complicating eclampsia, we are still far from being enlightened, definitely, as to the reason why albuminuria so frequently attends pregnancy. It is immaterial, in its clinical aspect, whether a distinct nephritis exists previous to or follows upon the pregnant state, or whether the condition existing during pregnancy be a distinct nephritis or a simple albuminuria, the complications arising are practically of equal importance.

Many theories have been advanced to account for the development of a nephritis or albuminuria, but their value is unfortified when applied to etiology as a whole.

That which has gained considerable ground, and which has been strengthened post-mortem, is pressure of the lower uterine segment upon the ureters, causing compression with subsequent dilatation of the latter; more especially is this so in primiparæ, where the abdominal walls are comparatively tense.

As the gravid uterus gradually enlarges, there is an added pressure upon the various adjacent vessels, causing a venous stasis. As regards the value of this pressure theory, it may be well to state that record has been made of various cases of ovarian tumors of large size, as also uterine fibroids, which were complicated with albuminuria, in which, after operation, the albumin disappeared almost immediately.

In this connection, I would offer the query: May not the reflex phenomena of nerve irritation, which so often accompanies the pregnant state, prove a prominent factor in the etiology? The state of the general nutrition, occupation, and habits of life of pregnant women, have little, if any, apparent influence in the etiology—a rather remarkable fact.

Having in mind pregnancy in its early stage, there can be no question of the substantial gain derived from a more careful attention to the state of the kidneys; especially in primiparæ, we should ever recognize the importance of early and repeated examination of the urine, enabling us generally to forestall any impending renal complication.

In a nephritis existing previous to pregnancy, examination of the urine should be made at the outset and continued during pregnancy.

Taking a known case of nephritis, existing either previous to or consequent upon pregnancy, we should bear in mind the fact that the management of such case is of prime importance; it should have reference particularly to three things: The relative amount of albumin present, the presence of casts, and as to their number, and a fair amount of urine excreted daily.

Very rarely we may find that examination of the urine will prove negative as to albumin, yet the microscope will detect an occasional cast; such a case demands our closest attention.

The presence of casts in the urine, a warning only too significant, would lead us to surmise a lurking danger of eclampsia during the final stage of pregnancy, during labor, or subsequent thereto.

A few words here on the subject of eclampsia. To enumerate the various explanations that have been given

and considered as important factors bearing upon the etiology of eclampsia, would require too much space, unwarranted in this short paper. The essential factor is the additional work thrown upon the kidneys through the elimination of excessive quantities of excrementitious matter in the later stage of pregnancy, aided no doubt by some intercurrent condition giving rise to an abnormal activity of the nervous system.

Eclampsic seizures not infrequently occur without any warning or previous history, or evidence of nephritis; though exceedingly rare before the sixth month of pregnancy, they may make their appearance at any time subsequent thereto, and the knowledge of an existing nephritis should place us ever on guard against threatened danger from eclampsia.

It is a singular fact that nephritis, as also eclampsia, may complicate one pregnancy and be absent in the next; or, that relapses are occasionally observed in recurring pregnancies.

Several instances of such can be cited from my own practice where there was an existing nephritis, in one case complicated with eclampsia two weeks before term, these cases being primiparæ, yet their subsequent pregnancies were unattended with any complications whatsoever.

I have notes of one case quite unique and instructive in character: Age, twenty four, primipara, giving a history of nephritis for two years previous to pregnancy, which, naturally continuing during the latter, developed in the eighth month into a pyelitis, with acute symptoms referable to the right kidney, following upon inclement exposure.

As in the case of eclampsia just referred to, the question of premature delivery, though entertained, was not acted upon, my desire being to follow the cases closely along lines seemingly rational in procedure; conservative measures of treatment, in both cases, aided by repeated examinations of the urine, were well rewarded, labor occurring at term unattended with any signs of danger, and convalescence uninterrupted.

To give an alarming prognosis because of existing albuminuria is certainly unwarrantable; with early and repeated attention given to the existing complication, the chances of the patient going to full term are correspondingly increased. The presence of casts and a greatly diminished quantity of urine excreted daily, possess special significance in the prognosis; even as regards the prognosis in eclampsia, experience has shown that the danger to life exists more in the violence of the convulsions than in their frequency. As to the time of occurrence of eclampsia, statistics compiled by Rosenstein (Ziemssen, vol. xv.) show that in 449 cases convulsions occurred in 121 cases previous to parturition, 260 cases during parturition, and 118 cases subsequent thereto, or during the puerperal period.

The ratio of eclampsia in primiparæ, as compared with multiparæ, is as 8 to 2. Not infrequently, these eclampsic seizures, though having a favorable termination to the mother, may have an unfavorable one to the fœtus.

In the treatment of the nephritis of pregnancy, we should dwell particularly upon the positive subjective symptoms: the character of the urine. Though we are not to undervalue the significance of the evidence furnished by the presence of albumin, it were well to shake off, in great measure, the inordinate fear inculcated in our minds by the teachings of the past, with reference to the dangers attending the presence of such; careful attention and rare judgment throughout is destined to be of great value in attaining the end sought for.

The continued free and regular action of the skin, kidneys, and bowels, by means of mild diaphoretics, diuretics, and saline laxatives, and cardiac sedatives, are the main therapeutical indications.

In the presence of eclampsia, the consequences are so momentous that a proper management is the first requisite to the accomplishing of a successful issue. We have before us quite an array of drugs or measures, by means of which we can combat certain emergencies. The functions of the skin being more under our control, can be promptly called into action; as a rapid and energetic diaphoretic, I have found pilocarpin of the best, given in one quarter to one-third grain dose, hypodermatically. To control the convulsions is of paramount importance; the reflex excitability of the spinal cord can best be overcome by inhalation of chloroform or nitrite of amyl, morphia hypodermatically, or enemata of chloral; where there is reason to apprehend recurrence, chloral acts favorably as a prophylactic; hot baths, at a temperature of 100° F., to 110° F., also serve a good purpose.

Venesection is rarely called for except in plethoric cases. Subsequent to the convulsive seizure or in the interval of such, the internal administration of infusion of digitalis, combined with alkalies, and even the fluid extract of jaborandi, will answer an excellent purpose in favoring the elimination of both solid and watery constituents of urine; veratrum viridi has also proved an efficient cardiac sedative.

Our resources to meet these subtle complications and dangers are of such a nature that a controlling influence is generally exercised by the above therapeutical measures.

The propriety of resorting to premature delivery forces itself upon us only when the attacks are severe and persistent; we must also recognize the danger of alarming hemorrhage and shock, in inducing labor prematurely.

When the convulsive seizures occur during labor, steps should be taken to expedite delivery consistent with the safety of the mother, if not the child; too active interference may prove dangerous, provoking reflex convulsive seizures.

In the words of Professor Parvin, "Although close to the gate of eternity, do not give up the battle, but fight to the water's edge; even the most desperate cases will at times rally and get well; such should inspire us with hope and confidence."

109 West Eighty-fourth Street.

NOTES ON DISEASE OF THE EAR AND UPPER AIR-PASSAGES IN APEX CATARRH.

By HOWARD S. STRAIGHT, A.M., M.D.,

Cleveland, O.

The inflammatory conditions of the ear and upper air-passages due to certain constitutional conditions—gout, rheumatism, syphilis, etc.—have all been described by competent observers and their importance impressed upon the profession for years. I can add nothing to these observations. An occasional case associated with such constitutional states presents itself to my observation, but while I see one such case, I see many whose constitutional condition is simply called "lowered vitality, general depression, etc.," by the various writers, and yet is never discussed. Apex catarrh[1] is the name I have chosen for this condition. A large proportion of the cases of throat, nose, and ear disease coming under my observation have also the condition called apex catarrh. This statement applies to patients from eight to forty years of age. Patients younger or older than this are less liable to suffer from such constitutional condition.

Patients who have an apex catarrh are very susceptible to colds. This cold may limit itself to any part of the upper air-passages or the middle ear, or the entire mucous membrane may be involved. These acute inflammations of the upper air-passages do not extend lower than an ordinary acute laryngitis. They differ in no respect from ordinary colds, except that the subjective symptoms of the patient are more marked.

The patient does not recover so rapidly, and the local inflammation in certain cases is much more obstinate than one would expect. In Cleveland slight thickenings of the anterior turbinated bones are almost universal. Many such cases suffer little because the condition has come on so gradually and because they know no other condition. They only realize that they had catarrh when the condi-

[1] Medical Record, January 6, 1894.

tion has been relieved. The great prevalence of ear disease everywhere is also well understood, and the connection between diseases of the nose, ear, pharynx, and larynx. In diseases of the ear and upper air-passages, as I see them, there is always two main considerations, the local and the constitutional, or the condition of the nose and the condition of the apices of the lungs.

You often see cases in which both conditions exist. The question to decide then is which condition, the local or the constitutional, is the one which has most to do in causing the disease of the ear, pharynx, tonsil, or larynx. These two conditions do not account for everything, I am well aware, and yet they claim consideration always as regards prognosis and treatment.

The importance of apex catarrh in ear disease was forcibly impressed upon me three years ago, when I was in general practice and a visiting physician to one of the hospitals. A boy, aged twenty, whose language no one could understand, was brought to the hospital. The only history we could obtain was that he had been sick for six weeks and had had no medical attention. He had a large accumulation of pus in the mastoid region, and the house surgeon had lanced the abscess before my morning visit, at which time I saw the case with one of the surgeons. The ordinary local treatment in such cases was proposed, and also it was suggested that calomel and rhubarb should be given because of the marked gastro-intestinal disturbance. I was not at all convinced that the local condition accounted altogether for the boy's condition, but thought it wisest to make no suggestion as to apices. A few days later he died from a profuse hemorrhage of the lungs.

Nearly one half of all the cases of ear disease in patients from eight to forty years of age that pass under my observation have also apex catarrh. Many have hypertrophic rhinitis. Both conditions require attention. While the increased susceptibility to colds accounts for the acute inflammations of the middle ear that are so often seen in patients with apex catarrh, I have been repeatedly surprised at the number of cases of chronic middle-ear inflammation that present themselves on account of their increased suffering under a similar constitutional condition. These patients are often people who have suffered for years from marked loss of hearing, and who have ceased to believe that there was any hope of relief. Upon the development of an apex catarrh they begin to suffer more from catarrh of the upper air-passages and to complain more from the subjective symptoms. The examination of the ear often reveals simply marked changes from an old inflammation, and yet no trace of any acute trouble. Such cases under creosote, without any local treatment, very soon regain their usual amount of hearing. Even cases of posterior adenoids in children over eight years of age are often associated with an apex catarrh. There is, of course, no connection between the diseases. Whether chronic catarrhal conditions of the nose, naso-pharynx, or pharynx predisposes a patient to an apex catarrh is an open question. For my part I do not believe it. I can understand how such conditions might be responsible for an ordinary chronic bronchitis, but not how an apex catarrh —a localized capillary bronchitis—could be dependent upon any such cause. Posterior adenoids in many cases cause few symptoms. If an apex catarrh occurs in such a patient, the posterior adenoids become more troublesome because of repeated fresh colds, and the patient presents himself for relief. The statement made as to posterior adenoids applies equally to chronic nasal catarrh.

The course of an acute follicular tonsillitis may be very greatly modified when occurring in a patient with an apex catarrh. The first few days there is nothing different from the ordinary symptoms. At the time, however, at which one expects the swelling of the tonsil to begin to subside, and the tenderness to diminish, they are found to be as marked as in the first two days of the disease. In some cases the swelling subsides about as fully as in the uncomplicated case, and yet the tenderness upon swallowing is entirely out of proportion to anything one can see in the throat.

Two years ago in February a girl, aged sixteen, presented herself at the clinic. She had been under observation three months before, for three or four weeks, with an apex catarrh. After improving upon creosote she had discontinued her visits. Three weeks before coming under observation the second time she had had an acute sore throat, from which she had not yet recovered. During this time she had been able to swallow only liquid food. The swelling of the tonsils had largely passed away, but the reddening was marked and the tenderness upon swallowing very great. A re examination of her chest revealed a well marked apex catarrh still present. She was given drop doses of creosote every hour. Within twenty-four hours she swallowed solid food. The local condition rapidly recovered, but the girl continued her constitutional treatment for a number of months.

This is simply one of many cases that have passed under my observation. They are by no means rare. Three such cases consulted me last week. A large number of the cases of subacute or chronic laryngitis in people in middle life are associated with an apex catarrh. Many of these cases have also a hypertrophic rhinitis. Both conditions have an influence upon the larynx. Both ought to be treated of course. What to promise such a patient as to the improvement of the throat for the first three months is a difficult question. Every such case improves in many ways when the course of the apex catarrh is a hopeful one. The great majority of cases recover of the laryngeal trouble within a few weeks after cauterization of the nasal hypertrophies and the administration of creosote. In a small proportion of cases, although the patient improves in every way, the laryngeal inflammation persists. After a few weeks' local treatment my rule is to inform such patients that they must not expect to be entirely relieved of the throat symptoms until they have regained their general health—until the disturbances in the mucous membranes, of which the inflammation of the larynx is only a part, shall have passed away. It is recommended that stubborn cases of chronic laryngitis be painted with increasing strengths of nitrate of silver solution.

I have never considered it advisable to pursue such a course in a laryngitis of this kind. If one failed to consider the constitutional condition of his patient, or did not know that exceptionally a laryngitis might pursue such a course, the local condition might receive over-treatment. There is, to my knowledge, no way of determining which case will promptly recover, and which case will persist, it may be, for months.

If the practitioner overlooks the constitutional condition, he fails to accomplish for the local condition what he otherwise might do. This statement I realize because I have only learned it from many a humiliation. I shall never forget a child, aged six, that I had treated for nasal catarrh for a number of weeks, and could not understand why the catarrh was not relieved. There was nothing in her appearance to make me suspicious of an apex catarrh. Finally, I examined her chest and found the key to the situation at one apex. Under benzosol her nasal condition passed away, almost at once. If either condition must be overlooked, the local is of lesser importance, and unless the specialist looks beyond the local condition the patient had better be in the hands of the sensible general practitioner. The local condition is easy of diagnosis, the patient has made the diagnosis himself, and will always insist on attaching undue importance to it. He has not as yet found out that his vitality is below par. It is useless to say much to such a patient in the beginning of his treatment. I aim to say enough to impress upon his mind my belief that there is more at fault than the local conditions. He soon sees for himself that my opinion of his case is correct. When this time has arrived he will accept the statement that he will be far from well when the local difficulty is relieved. It is not claimed that the course of the local condition is

especially modified by the knowledge of the catarrhal condition at the apex, *i.e.*, the catarrhal condition of the mucous membranes of the entire body.

Cases of apex catarrh recover upon any tonic treatment. The specialist who gives iron because his patient is anæmic, and then treats the local condition, is going to benefit his patient; or if he administer stomachics because there is a disturbance of the gastro-intestinal tract, the results will be satisfactory.

And yet how a specialist can intelligently treat the ear and upper air-passages without taking into careful consideration the facts herein stated is a mystery to me. There is little science in administering iron because a patient is anæmic. The cause of the anæmia ought to be found. If it is found to be due to an apex catarrh, creosote is a much more satisfactory remedy.

I might have summed up the entire paper in one or two sentences, and yet the subject has been treated at this length in the hope that this view of disease of the upper air-passages might be helpful. This is the result of years of study. Such conditions certainly exist in Cleveland. During 1888 and 1889 it was my privilege to work for a number of months in the ear, throat, and nose clinics in Vienna, and yet I never heard anything concerning the condition I have endeavored to describe in this and a succeeding paper. I never saw any observation made as to the pulse and temperature in the out-patients. It has been no easy matter to attempt to put my ideas on paper. Whether I have succeeded, the reader must judge.

A FEW WORDS IN REFERENCE TO LIVING CELLS VERSUS STAINING.

By WILLIAM MOSER, M.D.,

PATHOLOGIST TO ST. CATHARINE'S HOSPITAL, BROOKLYN, N. Y.

I RECENTLY stated [1] that "I was becoming more and more convinced that Virchow's teaching not to stain tissues was the best." Of course this does not apply to bacteriological examinations, but to general pathological work, such as the examination of tumors, etc. By this statement I did not intend to underestimate the value of recent advances made in processes of staining, such, for instance, as Golgi's method in the examination of the nervous system, but rather to draw the attention of the profession to the fundamental difference between a living cell and a dead cell—to living tissue and dead tissue—facts which have not been sufficiently considered. The great objection to our ordinary laboratory examinations lies in eliminating artificial products, and in the radical difference which must and does exist between the living and the dead cell. My own observations on the blood-cells, which I have lately published and to which I wish to revert merely for purpose of illustration, show that the red blood corpuscle which does not, as a rule, with few exceptions, stain with methylene-blue by our regular laboratory method, will do so when this substance is given internally. While the red blood-corpuscle will imbibe methylene-blue when given internally, it does not do this in all cases alike. I mean that it is influenced by various factors—by the condition of the cell. In some cases it will take weeks to become stained, while in pernicious anæmia it will stain readily. Even on the dead red blood-corpuscle this tendency in pernicious anæmia to imbibe not alone methylene-blue, but other stains, has previously been noted. But it becomes more manifest on the living cell. It has long been known that the nucleus of a cell has a special affinity for certain stains, viz.: Carmine, hæmatoxylin, aniline, hence the term "chromatin" (nuclein), which Fleming applied to it. During the process of karyokinesis the mass of threads formed are chromatic, while certain threads are achromatic (do not imbibe these stains). My observations on the nuclei of the white blood-corpuscles in which methylene-blue had been given internally, that is in dealing with living cells, prove to me beyond doubt that the term "chromatin" for the nucleus of a cell has not been misplaced. While it must be admitted that on the living cell the protoplasm imbibes the stain, it rarely does it so markedly as does the nucleus. It has long since been demonstrated that certain intra-cellular parasites, such as the plasmodium malaria, which usually finds its habitat within the red blood corpuscle, has, like the nucleus of a cell, a special affinity to imbibe certain stains. This can readily be seen by our ordinary method of staining this parasite with methylene blue in the laboratory. Indeed some writers [1] regard this affinity of the plasmodium for methylene-blue as quite characteristic, and think that this property will often enable us to distinguish it from other intracellular parasites. By giving the stain internally this affinity of the plasmodium to imbibe it can readily be demonstrated. And, strange to note, it will, in a brief space of time, cause the disappearance of the plasmodium from the cell, or, in fact, from the blood. My observations on this point confirm those of Matienzo,[2] who first made known this fact. It was for that reason that he recommended methylene-blue in the treatment of malaria in some cases in place of quinine, etc. It is to be regretted that it does this, because if the living cell with its parasite retained the stain, like the nucleus or nuclei of the white blood-corpuscles, what a splendid opportunity it would afford us to study the life history of the plasmodium malaria! I believe we may yet find a stain to do this. I have tried eosine, but was unsuccessful It is possible that we may be more successful with carmine or hæmatoxylin. It is apparent that while we can stain the blood-cells during life we cannot do this with all cells in the body. If this were so, what a difference it might produce in histology and pathology!

158 ROSS STREET, BROOKLYN, E. D.

[1] St. Catharine's Hospital Report, 1893.

TREATMENT OF FRACTURES AND SPRAINS OF THE ANKLE BY MASSAGE.

By ALEXANDER C. WIENER, M.D.,

CHICAGO, ILL.

WHILE there has been great activity in all branches of operative surgery, and strenuous efforts have been made to improve present methods and to introduce new ones, yet in the treatment of fractures there has prevailed a manifest reluctance to change the old and approved methods. What else can account for the total disregard paid to the theses delivered by Lucas Championnière at the Paris Société de Chirurgie, June 26, 1886, on the treatment of fractures by massage? His ideas suggested a complete revolution in the treatment of fractures, although this method of treatment has nowhere received such general recognition as in France.

The treatment by massage fulfils in general the three following conditions: 1. It shortens materially the time of recovery and lessens the period of ossification. 2. It gives better results functionally. 3. It lessens the pain of the treatment.

Since then massage has been recommended for all articular and periarticular fractures; but in no case has it produced more striking and indisputable results than in the treatment of fractures of the ankle and the various sprains of the foot. In such cases this is the classic treatment. When we consider that the expectant treatment of immobilizing the foot in splints or in plaster requires at least thirteen weeks for the recovery of a fracture of both bones, two-thirds of this time being required to overcome the stiffness of the joint and the atrophy of the muscles resulting from the immobilization, a method of treatment that diminishes the time by one-half is worthy of consideration.

A simple sprain of the foot treated by the expectant method, that is, by bandages and rest, renders the foot useless for twenty-five days on an average, whereas the patient treated by massage can move about freely after

[1] Adler: Protozoa and Their Relation to Carcinoma. American Journal of the Medical Sciences, January, 1894.

[2] La Gaceta Medica, 1893.

eight days. Twenty-five per cent. of all the fractures that occur affect the ankle. The sprains to which this joint is subject are numberless; and what a wide field this opens to the physician, who, as a rule, prefers to take an active part in the process of recovery rather than to apply a bandage and see himself reduced to the part of a passive spectator.

The diagnosis of fractures of the ankle offers no difficulties; but I beg to be permitted to say a few words regarding the mechanism of the different fractures, since an understanding of this is essential to successful treatment. Fracture of the inner malleolus is produced by the forced lowering of the inner and raising of the outer margin of the food. The deltoid ligament being the first to meet the force is, as a rule, not torn, but tears off the end of the tibia, to which it is attached. The foot is then allowed to roll around its inner border into a most pronated position. The outer malleolus is driven against the outer border of the calcaneus, and in most cases the end of the fibula breaks off six or seven centimetres from its lower end (Pott's fracture). The next most frequent cause of fracture of the inner malleolus is dorsal hyperflexion of the foot. The simple fracture of the outer malleolus (Dupuytren's fracture) is produced by forcing the foot down on its outer border. In many cases only the outer ligament, that is, the ligament calcaneo-fibulare, is torn in consequence of the supination of the inner border of the foot, but usually the lower three centimetres of the fibula are broken off transversely. The fragments are not usually dislocated, being held in place by the ligament tibio fibulare. The action of the force upon the joint affects only the ligaments immediately. If they are not torn they transmit the force to their place of attachment to the bone and thus a solution of continuity is produced. The mechanism of the simple sprain of the ankle joint and its fracture is the same, the difference lying only in the intensity of the force exerted. This difference is still slighter when we consider the great extravasation of blood in the ankle-joint which is produced in tearing the ligaments.

Massage has for its object the prevention of the normal degeneration and the removal of the blood from the joint and the œdema from the soft parts. The treatment during the first eight days is of the utmost importance. The blood must not be allowed to coagulate; the process of regeneration in the bone, which begins, at the latest, a few hours after the injury, must be accelerated by stimulation.[1] The pain must, as a rule, be relieved in three or four sittings. Massage must begin immediately, provided there is no dislocation of the bone. In fractures of both bones the astragalus has lost its position, the foot wabbles about and frequently the astragalus is dislocated backward. As the bones always consolidate in the position which they take of themselves or in which they are placed, an immediate reposition, if necessary under an anæsthetic, and retention in this position are indispensable. These are the only cases in which immobilizing is indicated. The foot is placed with light pressure in a position perpendicular to the leg, and then placed in a plaster cast; a woollen or silk stocking may be used next to the limb and a three inch plaster-of-Paris bandage applied. The bandage reaches to the upper third of the leg and encloses the whole foot except the toes. For strengthening the cast at the sole of the foot, a strip of paste-board may be included. After three days a return to a wrong position need not be feared. The bandage is removed and treatment by massage begins. If, as occurs occasionally, the astragalus again becomes dislocated, a paste-board splint may be made, which can be easily put on or removed. Massage of recent sprains or fractures is to be practised under the same aseptic precautions as for recent wounds. The foot and leg are to be thoroughly cleaned with warm water, soap, and brush, the hair removed and the skin then carefully dried. The physician's hands must also be thoroughly cleaned. Disinfecting agents must not be used, as they irritate the skin too much. The epidermis always presents minute openings through which pus-forming agents may penetrate and find rich soil in the extravasated blood. The limb is then well anointed with sweet-oil or vaseline, and placed on a solid support. If there is a tendency to a return of the dislocation in the first few days after the removal of the bandage the foot must be held in the proper position by an assistant. In simple sprains I prefer to apply massage while seated, the patient's limb being supported on my knee.

Massage consists in a gentle pressure of the volar surfaces of the united fingers moving in a centripetal direction. At first one must avoid touching the fracture and must not continue the sitting too long. The first treatment should not exceed ten minutes. From the fourth sitting on, each one should occupy at least twenty minutes. For practical reasons I would have only one sitting a day and make them somewhat longer. In making the passage from the periphery toward the centre, the blood exudate and œdematous fluid are pressed toward the lymph spaces and urged toward the heart. How powerfully the lymph currents are stimulated is shown by the fact that after a few days the lymphatics of the legs and thigh become visible from the coloring matter of the blood which they contain. The hyperæmia of the veins and the troublesome throbbing and heat in the joint are also promptly removed and the rich arterial blood supply promotes the healing of bones and ligaments. The muscles preserve their elasticity and the equilibrium of their metabolism; their contractions assist the flow of the blood into the more deeply lying veins. The painful contractions which follow the over-stretching of the muscles and tendons disappear rapidly. The most immediately favorable result of the massage for the patient is the fact that the treatment after three or four painful sittings becomes almost painless; for, with the removal of the extravasation, the pressure on the sensory nerve ceases. At the end of the sitting the abundant oil on the surface is removed with alcohol, which has a pleasing, cooling effect on the stimulated skin. The fractured limb is wrapped in a cloth moistened with cold water and the air kept out by a covering of oil-cloth. These coverings are changed every two or three hours. A little acetate of lead or witch-hazel may be added to the water. Ice should never be applied to the fracture; it coagulates the extravasated blood too rapidly and produces anæmia; in short, all the beneficial effects of the massage are undone by ice. Hot water, 100° to 105° F., in form of local baths applied for half an hour each day assists the massage by removing the extravasated fluid.

The second essential in treating sprains and fractures by massage is not to immobilize the joint. All immobilizing of the foot hinders the recovery and lessens the usefulness of the foot. The only exception to this rule has already been mentioned. Since in fractures of the inner malleolus the foot is always inclined to be pronated, that is, to be flat-footed, especial attention should be given to the position of the foot. The leg should rest on a solid, somewhat elevated support. The sole of the foot presses against a smooth, polished, square board, which is placed at right angles to the support, and in such a manner that the inner border of the foot stands higher that the outer. If the astragalus during the treatment is inclined to become dislocated backward, an elastic cushion should be placed under the heel, so that the bone will be held in place by the weight of the leg. The pes valgus position of the foot is most easily corrected by the application of an elastic flannel bandage; but the joint must be left freely movable. The advantages in not immobilizing the joint are apparent. The flexors and extensors of the foot remain in continuous activity and in the perpendicular position of the foot the antagonizing muscles maintain their equality. The pressure of the foot against a fixed surface provokes continuous elastic movements in the ankle around a transverse axis, which prevents the formation of synovial adhesions and atrophy of the articular cartilages. The mobilization of the joint fulfils for

[1] Formativer Reiz, Virchow.

the most part the same indications as the massage; both are equally important factors in the cure, they combine and co-operate with each other. The maintenance of the muscular tonus produces a continuous auto-massage. The patient himself, not being hindered by any bandage, is continually tempted to test his progress; he makes active movements in the injured joint, even when, as at first, the sensations are not agreeable; he is interested in hastening the progress of the cure by its own activity. According to my experience, it is not advisable to make passive movements.

In more serious sprains of the foot, the recovery requires four to eight days; in simple fractures of the outer malleolus ten to twenty-one days; in fractures of both ankles, especially with dislocations of the fragments and luxation of the astragalus, the time is variable, usually from four to six weeks. The eight clinical histories which Lucas Champonnière gives in his lecture are all cases of fracture of the outer malleolus. Only once was the inner malleolus also dislocated. In no case was there dislocation or abnormal mobility in the ankle-joint. They were all treated with massage from the first day without immobilizing bandages. Champonnière considers the first day on which the patient can walk without assistance as the day of recovery. The shortest time was twelve days, the longest twenty-eight, average, twenty and two-tenths days.

In the City Hospital in Magdeburg, sprains and fractures of the foot are treated by massage since the year 1888. I had the honor of proposing the new mode of treatment to my chief, Dr. Hagedorn, lately deceased, and we obtained results which were new and surprising to both of us. The number of cases treated in the years 1888 to 1891 was about one hundred. We considered the patient cured when he had recovered the use of his foot. The average duration in sprains was seven days, in single fractures of the outer malleolus twenty days.

It would take too long to illustrate the simple cases by clinical histories. I shall limit myself to a few typical cases and shall give the preference to the severer one.

Case I.—Man, twenty-eight years of age. Fracture of the external malleolus without dislocation. Considerable extravasation of blood in the ankle-joint. Massage. No bandages. Got up in ten days and walked without a cane. In twenty-two days able to work.

Case II.—Strong laborer, forty-two years of age. Admitted into the hospital November 6, 1888; discharged December 8th; the time, thirty-two days. Fracture of the left internal malleolus; dislocation of the lower fragment, 2 ctm.; foot not actively movable, hanging loose at the ankle-joint; traumatic swelling of the whole leg below the knee. Careful reposition. Massage did not remove extravasated blood as rapidly as usual.

Case III.—Blacksmith, twenty-three years of age; admitted, July 29, 1888; discharged cured, August 20th; time, twenty-two days. Fracture of both malleoli with considerable dislocation of the fragments. Pes varus position. After careful reposition, massage; but as it caused too great pain, it was discontinued for two days; limb placed in Volkmann's splint. From August 1st the pain decreased rapidly. Massage twice a day, ten minutes each time. August 8th, the patient was able to stand on his foot; foot freely movable in all directions.

Case IV.—Healthy sailor, forty-six years of age, admitted October 30, 1888; discharged December 13th; time, forty-four days. Typical Pott's fracture. Foot hanging loose from the astragalo-tibial articulation; an audible sound in making passive movements. Reposition, massage. When discharged had still slight œdema evenings.

Case V.—Typical Pott's fracture. Admitted November 14, 1889; discharged December 12th; time twenty-eight days. Foot after reposition inclined to become dislocated backward, necessitated the use of Volkmann's splint for the first seven days in connection with the massage treatment. Tendency to talipes position; recovery complete. Considerable callus on each side.

Case VI.—Fireman, twenty-five years of age; admitted February 10, 1890; discharged March 5, 1890; time, twenty-three days. Typical Potts' fracture; great extravasation of blood in ankle-joint, which could not be actively moved; no dislocation. No immobilization; massage. February 16th all movements of the ankle-joint painless; beginning callus formation.

Case VII.—Laborer, forty-six years of age, admitted December 6, 1888; discharged February 16, 1889; seventy-two days. Pott's fracture of the left ankle; great dislocation of the foot outward (pronation); considerable extravasation of blood into the ankle-joint. Massage; the foot was held in pes valgus position by wrapping in flannel; formation of callus weak at first; resorption of the extravasated blood followed promptly. On the twenty-first day of treatment, the patient got out of bed contrary to orders and walked about, before the ends of the fracture were consolidated. The foot assumed in consequence a flat-footed position very difficult to correct. Extensive formation of callus did not begin until the eighth week. At the time of his discharge, the ankle joint was freely movable actively and passively in all directions; position of the foot normal; walking without pain.

All these cases were injuries occurring in healthy persons. The period of treatment exceeded six weeks in only one case. This case is given on account of its abnormal duration and the lack of sufficient formation of callus. As a rule, an abundant callus formation is characteristic of the treatment by massage; the periosteum reacts to the formative stimulus of the massage so actively that later on in the treatment the point of fracture had better be left out of the field of massage. According to more recent experience it would be better in such cases to allow the patient to move about with ankle encased in a well-fitted plaster bandage properly padded with a thin layer of cotton. At first, from motives of prudence and because we could not free ourselves entirely from the immobilizing of the joint, we used Volkmann's splint, especially at night. Later, in severe dislocations, as described above, plaster-of Paris and pasteboard bandages were used. If the patient is restless or asleep, or if he has delirium tremens, a light pasteboard bandage may be used.

The duration of the treatment depends not only on the severity of the fracture, the amount of the extravasation and the recurring faulty position of the foot, but also on the general health of the patient, his determination and energy, as well as the skill of the physician and his ability to render the patient able to bear the very considerable pain of the first few sittings. In general, treatment requires longer in women than in men. Contra-indications in the treatment of massage are: Psychical disorders, wasting diseases (tuberculosis, diabetes) as well as all synchronous acute or chronic, septic and pyæmic processes. Injuries to the skin over the region to be treated must be protected against infection by sealing the wound with iodoform collodion and aseptic absorbent cotton.

When the patient again returns to his work œdematous swelling of the injured joint sometimes occurs, or the foot, when too severely used, again takes the flat-foot position. To prevent this the patient must for a few weeks support the injured limb with a bandage of elastic flannel or silk, so as to raise the inner margin of the foot. Leather shoes, not too wide, but comfortable, with a cork sole on the inner side of the foot, prevent an incorrect position. For rapid resorption of the superfluous formation of bone, tepid salt baths may be used and rubbing with an ointment containing iodine and iodide of potash.

The treatment of fractures and sprains must undoubtedly be conducted by the physician himself, and only when no more complications need be feared should the massage be intrusted to a skilful and experienced nurse.

It is to be regretted that massage, the salutary effect of which on the organism has been recognized by the oldest civilizations, such as the Chinese, and later the Greeks,

should be degraded to unworthy purposes in our modern civilization and should be practised by people whose total ignorance of the human organism and the characteristics of diseases occasions more harm than good. I am, therefore, well aware of the difficulties which have yet to be overcome before the practice of massage in its various forms will be taken up by the physician and recognized by the public as a necessary and desirable accessory of the conscientious physician in the exercise of his profession.

Progress of Medical Science.

Renewed Virulence of Staphylococci after a Long Period of Latency.—Dr. Schnitzler relates the case of a patient who, at the age of seven years, received a severe injury to the right leg, resulting in a localized osteomyelitis of the tibia. This subsided in about six months, after discharge of pus and sequestra (*The British Medical Journal*). The patient had been quite free from symptoms, local or general, for thirty-five years, when he was suddenly attacked by severe pain in the former seat of disease, attended by much general febrile disturbance. The signs of localized osteitis quickly became manifest; there was no discharge. On chiselling through the dense and thickened bone at the seat of disease, a closed cavity, the size of a walnut, containing granulations and pus, was found. In the granulations staphylococcus pyogenes aureus was present in a very virulent condition, as shown by inoculation of rabbits. Schnitzler adduces reasons for believing that the cocci had lain dormant in the cavity for the long period mentioned, being brought once more into activity by circumstances unknown. He rejects the supposition that a fresh supply of cocci had been received into the circulation and deposited at the diseased spot. He points out that staphylococcus pyogenes aureus is capable of existing upon nutrient media under unfavorable conditions for a very long period, and argues that a cavity containing granulation tissue well supplied with blood, such as was present in this case, offers a very favorable prospect for the prolonged existence of micro-organisms. There is frequent renewal of nutriment and removal of waste products. The case, in Schnitzler's opinion, shows that pyogenic cocci are capable of remaining latent in the human body for a great period of time, again becoming virulent on some chance disturbance of the normal processes of metabolism.

Starting-Points of Tuberculous Disease in Children.—At a recent meeting of the Medical Society of London, Dr. J. Walter Carr read a paper based on 120 necropsies upon children suffering from tuberculous disease, in which he drew the following conclusions:

1. Tuberculous disease commences usually in the glands, the liability being at its maximum during infancy and early childhood, and rapidly decreasing in later childhood. But, of the 120 cases, the disease had almost certainly commenced in the glands in 70, or 58.3 per cent. (including 13 in which glands only were involved), and in 17 more, or 14.2 per cent., there was considerable probability at least that the glands were the primary focus. Including doubtful cases, the glands formed the primary focus in 64.5 per cent. of those under five, and in only 37 per cent. of those above that age.

2. Tuberculous lesions in the cervical glands, as in the joints, may arise by infection through the bloodstream, but caseation of the bronchial and mesenteric glands, when primary, is usually, if not always due to direct infection from the organ with which they are connected, it having been shown that bacilli may pass through the lungs or the intestinal walls without producing any recognizable lesion, and that they then enter the lymphatic channels and not the blood-vessels.

3. Tuberculous disease starts much more frequently in the thorax than in the abdomen, and certainly far more often in the thoracic than in the mesenteric glands. Of the 120 cases, in 79 the disease probably started in the thorax (in 54 certainly, and in 12 possibly in the bronchial glands); in 20 in the abdomen (in 12 certainly and in 2 possibly in the mesenteric glands); and in 6 in either one or the other cavity. In only 2 cases were the cervical glands the probable primary focus. The conclusion is that, though infection undoubtedly does occur through the intestines, and especially (as experiments on animals have shown) through milk, yet infection through air is by far the more frequent and important. The disease is so commonly generalized in children that figures merely giving the frequency with which different parts are affected are of little value, the important point being to ascertain where the disease is most advanced—that is, where it probably commenced.

4. Caseation of internal glands, from the frequency with which it is found after death, must often exist alone and quite unsuspected, being doubtless in many cases quite impossible of diagnosis, and it is very necessary to realize its frequency and importance when dealing with obscure febrile conditions in children.

5. In regard to treatment, prophylaxis is by far the most important; and as it is probably impossible to prevent bacilli from obtaining access, we must try to increase the resistive powers of the system to their entry, above all by keeping the mucous membranes healthy, by dealing promptly with, and if possible preventing, rickets—the great cause of catarrh in early childhood—and by taking especial care of children during convalescence from acute specific fevers, which so depress the vitality of the body generally, and the resistant power of the mucous membranes, as well as the filtering power of the glands in particular.—*British Medical Journal.*

The Cause of the Mal de Montagne Experimentally Determined.—The Paris correspondent of *The Lancet* writes that it is proposed to bore a tunnel or chimney extending from the base to the summit of the Jungfrau. In this chimney, whose height will be four thousand metres, it is intended to install a lift destined to convey passengers to the top of the mountain; but sinister warnings of the dreaded *mal de montagne*, which, it is said, will surely make the tourist repent his temerity, have brought the project to a standstill. Struck by the fact that this malaise affects mountain-climbers at an elevation of about three thousand metres, while aëronauts only suffer when they have reached double that height, M. Regnard concludes that the difference is explained by the factor, muscular fatigue, which is present in the first and absent in the second case. In order to solve the problem he places under a bell jar two guinea-pigs equally developed, of whom one has to work a wheel (the climber) while the other is at rest (the aëronaut). The air of the bell-jar is then progressively exhausted so as to reproduce the atmospheric conditions obtaining at different heights. At a pressure equivalent to three thousand metres the climbing guinea-pig showed signs of distress, and at four thousand eight hundred metres he renounced the struggle and remained lying on his back. The aëronautic guinea pig, on the other hand, appeared quite comfortable up to an elevation of six thousand metres, and his condition became serious only at a height of eight thousand metres. This experiment appears to prove that, although some of the symptoms of the *mal de montagne* are doubtless due to the rarefaction of the air, the chief determining cause is fatigue, and the resulting exaggerated consumption of oxygen. M. Regnard opines that tourists who venture on the Jungfrau-lift expedition will reach the top in good condition. Should this prognostication be true, it constitutes one more proof of the usefulness to speculators of the much-maligned experiments conducted in the physiological laboratory. Rabid anti-vivisectionists cannot now, however, logically avail themselves of the above-mentioned mode of transit to the top of the Jungfrau.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, September 22, 1894.

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

THE report of Dr. Biggs to the New York City Health Department on the value of the antitoxin treatment of diphtheria has naturally excited great interest in lay as well as medical circles. The work in this direction was not unfamiliar to our readers, for reports of it have been published from time to time in these columns. It is rather unfair that Professor Koch should be getting the credit, since it is not he who has been making the investigations, but Behring, Aronson, Katz, Surinow and others. Early in August, Dr. H. U. Walker gave an account of the results that had been obtained in Berlin (*British Medical Journal*, August 18th). Katz's report of the employment of Aronson's antitoxin in the Berlin Children's Hospital shows best what the effects of treatment are.

Dr. Ratz states that, "In the last three years, 1891 to 1893, 1,081 cases of diphtheria have been treated in the hospital, of which 421, or 38.9 per cent. died, the mortality in the respective years being 32.5 per cent. in 1891, 35.4 per cent. in 1892, and 41.7 per cent. in 1893. From the commencement of this year up to March 14th, 86 cases have been treated, with 38 deaths, or a mortality of 41.8 per cent. On the latter date the antitoxin treatment was commenced and employed in 128 out of 151 cases admitted to the hospital, 23 cases not being subjected to it for various reasons. In the 128 cases so treated only 17 deaths occurred, the mortality thus falling from 41.7 to 13.2 per cent. In all his clinical observations Dr. Katz is able to say that on no occasion could any deleterious effect be ever attributed to the employment of the antitoxin solution. If renal inflammation did occur, it followed quite a normal course, no bad effect could be observed upon the rhythm or tone of the heart and pulse.

Quite lately Dr. Katz has inoculated 72 children who had been exposed to the disease. Of these only 8 were attacked, and they so slightly as to be free from any evil consequences.

Dr. Thomas Eastes reports, in the *British Medical Journal* of August 25th, seven cases of diphtheria successfully treated by the new method. He also gives a description of the technique which we reproduce here. He says:

"The syringe I have used is Debove's, a beautiful but complicated and expensive instrument. Any syringe will do that can be sterilized either by boiling or immersion for a few hours in a five per cent. solution of carbolic acid, but it is better if it will hold at least 5 c.c. (85 minims). The skin should be washed, and then cleansed with absolute alcohol where the injection is to be made. The dose should be 1 c.c. to produce immunity for any aged over three, half that for younger children. For cure during the first two or three days under two years of age, 2 to 3 c.c.; from two to ten years of age, 5 c.c.; over ten years of age, 10 c.c.; after the third day in a severe case twice as much. If worse symptoms should ensue after the injection the dose should be repeated in twelve hours. It seems doubtful whether any symptoms whatever are caused by the injection, and in cases of exceptional severity larger doses still should be used. Usually there will be distinctly less œdema and a fall in temperature in from twelve to twenty-four hours, and a most marked improvement in the general condition in forty-eight hours. The advantages of this treatment are many in addition to its efficacy. The injection once for all into the tissues of the back gives very little pain, and there is no more interference with the patient required at all—no more painting, spraying, or swabbing the throat, no tearing off false membrane—and consequently a most welcome diminution of suffering and distress."

In this connection it may be stated that simpler methods of preparing an antitoxin have been described by Surinow (*Ber. Klin. Woch.*, July 23d). On the ground of the change from toxin to antitoxin being a chemical one, he has endeavored to induce, by oxidation or reduction processes, properties in the serum of healthy or diseased animals like those possessed by immune animals. Positive results were obtained only by electrolysis. By exposing 100 c.c. of dog's serum to a current of 120 to 140 milliampères from three to four hours, the author obtained a serum which, when injected into animals, produced a rise of temperature. The change produced in the serum is due to an alteration in the albumin. Many animals were infected with diphtheria, etc., and then treated with this simple electrolyzed serum. They all died, however, notwithstanding that a high temperature was produced. The author then took ordinary serum, or its constituents, and inoculated it with diphtheria culture. After some time toxins were produced. A globulin culture was also made, but in this no toxins were developed. The serum or serum albumin cultures were then electrolyzed, and it became evident that the toxins could then be converted into antitoxins. Animals were inoculated with diphtheria, and then treated with the antitoxins thus obtained. Some of the experiments were not successful, but it was thought that a more powerful antitoxin could be obtained. It was found out that electrolysis of a bouillon diphtheria culture also converted the toxins into antitoxins. After a certain time a color reaction is developed in the electrolyzed fluid, and at this time the electrolysis should cease. Some successful experiments are then recorded where the antitoxins from this electrolyzed bouillon were used instead of those from electrolyzed serum or serum albumin. It was found that a single large dose administered subcutaneously was more efficient than divided doses. The antitoxins were harmless to the animals, and preserved their properties for a long time.

SARSAPARILLA, CELERY, AND RED CLOVER.

We have at different times referred to the curious popularity of sarsaparilla and its growing rival, celery. It is abundantly shown that neither of these plants have any real therapeutic properties. A third candidate for popular favor is "red clover," and this seems equally deficient in therapeutic or physiological properties. According to the announcements clover extract has a "great and growing reputation as a blood-purifier, and as a specific for cancers." The number of individuals whose "cancers" are said to have been aborted or dispersed by clover-tea is legion. It is not only good for "cancers," but for other morbid productions, even "carbuncle" and "scrofula."

It is needless, says the *Boston Medical and Surgical Journal*, to say that no medicinal principle has yet been obtained from the trifolium. We shall expect next to see an extract from the potato or turnip vaunted for cancer or syphilis! There is, by the way, still a belief in certain localities that the tomato is a cause of cancerous growths! Our contemporary adds: It is hard to account for the repute that clover has acquired among the laity of this country as a remedy for cancer. In many parts of New England we know it to be almost impossible for a person to have a suspicious growth of any kind without being urged to take clover, and the urging is persistent. In a certain neighborhood near Boston, one woman, afflicted with growing scirrhus, is said to have consumed in extracts and infusions of red clover the product of a ten acre lot; but without saving her life. The fact that the cancers do not disappear, despite the free use of the antidote, appears to detract in no measure from the sale or use of the preparation.

There is no sound basis for the reputation which red clover has acquired, and the only persons who have ever derived any advantage from the use of clover in cancer, furuncle, or various "humors," are the venders of certain extracts, fluid and solid, which are in growing demand.

THE GAS HABIT.

The so called "exposures" made by the daily papers are often sensational, exaggerated, and unjust. A reporter of *The Herald*, however, has done some service by investigating one of the compound oxygen establishments in this city. Oxygen is a substance which to the lay mind represents all that is fresh and pure and life-sustaining in the line of gases. "Compound oxygen" is a term which gives the impression that it is something several times better than oxygen. Hence it is a name that has long been popular with the fakirs. Some advertised preparations of it have been inhaled, some taken internally, all with the result of receiving numerous testimonials. The establishment whose methods have lately been exposed dispensed under the name of "compound hydrogen" a gaseous mixture of about two parts nitrous oxide and one part atmospheric air. This was administered by means of an elaborate apparatus which enabled the patient to recline at his ease and inhale the gas slowly and intermittently. The stimulant effect of the mixture was thus obtained without inducing anæsthesia or unconsciousness. Patients describe the effect as very delightful, and many returned for weeks and months in order to enjoy this seductive form of inebriety.

There seems little doubt that a gas habit or a form of gas-inebriety can be induced by this promiscuous administration of the "compound oxygen." One case indeed is on record (Kobert's *Intoxicationen*) in which a person acquired the habit and eventually became insane. The ether habit and chloroform habit are well known, and there is no reason to doubt that given the opportunity, the nitrous-oxide habit may be formed also. The effects of this gas are usually very temporary and it would require a good deal of time for serious results to ensue, provided the anæsthetic were given with care. But it is well known that nitrous oxide is not a perfectly safe substance. Deaths from its use have occurred, and cases of serious nervous disorder are reported to have followed its administration. It is in fact a poison, and we believe that it should not be administered except under the direction of duly qualified persons. The dispenser of the "compound oxygen" is said not to be a physician, and he certainly is not registered as such. Establishments for giving nitrous oxide to patients would come in the same class as establishments for giving chloroform or ether or administering hypodermics of morphine. There is no use for such places; they do not subserve the public good; they are, on the contrary, dangerous, and we should judge entirely unlawful.

It is about time that "compound oxygen" humbugs were exposed and the people made acquainted with their true character.

THE TREATMENT OF CHRONIC HEART DISEASE BY BATHS AND MASSAGE.

The mechanical treatment of chronic heart disease has now been accepted by the profession as having a certain, though limited, value. This treatment, as oftenest employed, consists in regular pedestrian exercise over fixed courses which, as a rule, have a gradual ascent. Gymnastic exercises at home, and baths, supplement this.

In addition to this method of cardio therapy, we hear periodically of the special method devised by the brothers Schott, of Nauheim. A pilgrim to that spot, Dr. W. Bezly Thorne, has recently described again the remarkable efficacy of the Schott treatment, and has reported a number of illustrative cases (*Lancet*, May 5, 1894). The patients who are treated at Nauheim follow a method which has been elaborated "after eighteen years of study," though we doubt if there is much difference between what is done now and what was done eight years ago. The measures employed consist of baths and passive and active movements known as *Widerstandgymnastik*. The most frequently employed are those containing one and a half per cent. of sodium chloride, one and a half per thousand of calcium chloride and salts of iron, with a variable proportion of carbonic acid gas. They possess a natural temperature of 88° to 95° F. The baths are given daily, and are followed by an hour's repose in the recumbent posture; while in the bath the patient is subjected to various movements. The extremities are slowly flexed, extended, abducted, adducted, rotated, etc., by the operator, while the patient breathes slowly and makes resistance.

The effects are manifest in a diminution of cardiac dilatation and slowing of the pulse rate. The exact technique, of course, can only be acquired by experience, but the baths themselves can be artificially prepared, and there seems to be no reason why physicians in this country should not be able to apply successfully the treatment.

THE PNEUMATIC CABINET.

Those who have heard that, some four years ago, the last of the stock of pneumatic cabinets had been sold for old iron, will perhaps be surprised to know that Dr. C. E. Quimby, according to a reprint just received, has not given up his instrument nor allowed this method of treating phthisis to pass wholly into oblivion. While acknowledging his ignorance of what the cabinet can do alone in the cure of phthisis, he claims to demonstrate that, scientifically applied, it must act favorably in conjunction with other measures of proven value. After six years' experience, the writer believes that "from seventy-five to eighty per cent. of localized tuberculosis, if seen reasonably early in the first stage, can be brought to and kept in a condition of practical cure by the use of the pneumatic cabinet and adjuvant measures other than climate." Disseminated tuberculosis subacute and third stage cases are found to be correspondingly relieved and benefited.

The alternation during each respiration of negative differentiation and negative pressure is, the writer believes, the most comprehensive motion of the cabinet, and one which has received little attention. The value of full inspiration until circulatory equilibrium is established and exhalation into the rarefied air of the cabinet, is explained, and it is shown how the blood is pumped into and out of the lung in the physiological direction without increase of vascular tension.

In fine the claim is advanced, that the cabinet acts curatively, to a greater or less degree, upon all the factors of phthisis except the bacillus itself.

News of the Week.

Further News About Diphtheria Antitoxin.—In the *Berliner klinische Wochenschrift* of September 3d, Behring publishes a paper, in which, among other points, he deals with the question of dose. He states that the serum prepared and tested under his own supervision and that of Ehrlich is now issued in two forms—No. I. and No. II.; No. II. is two and a half times stronger than No. I. No. I. is sufficient for the treatment of a case of diphtheria in a child under ten years of age, if it be seen on the second or third day. In cases of longer standing, in those of a very severe type in young children, and in adults, a repetition of the injection will be necessary. No. II. serum acts more surely and rapidly in these cases, but, owing to the difficulty of rendering the animals sufficiently immune to provide a serum endowed with immunizing powers so strong, a constant supply cannot be insured. The estimation of the exact strength of the serum is a difficult matter, and it must be recognized that the strength is liable to vary with the commercial source from which it is obtained. Behring and Ehrlich have devised a method of expressing the strength in figures. Their No. I. (quality and quantity) contains 10 c.c., which is equal to 600 antitoxin normals, and is sufficient for one case with the limitations already mentioned. No. II. contains 11.5 c.c. of a strong serum, and is equivalent to about 1,500 antitoxin normals. Behring now estimates that the death-rate of cases treated within forty-eight hours of the onset of the disease with No. I. ought not to exceed five per cent. The dose to be injected as a prophylactic in persons liable to be exposed to diphtheria is set down by Behring at 60 antitoxin normals, or one-tenth of No. I. After infection, that is during the incubation stage, he believes that 150 antitoxin normals ought to avert the development of the disease.

M. Crispi will soon be operated upon for cataract.

A Monument to Volkmann was unveiled on September 4th, and one to Dr. Testelin, of Lith, on the same day. A monument to Quatrefages has recently been completed.

Dr. Theophilus Patterson, of Salem, N. J., died at his residence in that city on September 7th. He was born in Salem County in 1827, and was graduated from the Jefferson Medical College, Philadelphia, in 1848, being a pupil of Dr. J. K. Mitchell, the father of Dr. S. Weir Mitchell. He almost immediately began practice in Salem and lived there in the active exercise of his profession for forty-six years. He was always interested in educational matters, and was largely instrumental in raising the standard of the public schools in Salem during a number of years in which he held the office of city superintendent. A wife and four children, one of them also a physician, survive him.

Dr. Horace Ingersoll died a few days ago at Salem, Mass., at the age of eighty-three. Besides medicine he also, at different periods, studied and practised theology and law. He was a friend of Hawthorne, and was credited by the latter as being the one who suggested the incidents in the "Scarlet Letter."

Cycling in Paris.—A Paris correspondent writes that there are over one hundred thousand cyclists in that city, that nearly all the leading physicians ride, next come the lawyers, then the deputies, officers, and even the Institute; the family physician prescribes the exercise as the most health-giving ever devised.

Japanese Nurses.—A corps of trained female nurses has been despatched from the Tokio Training School to the military hospital at Seoul, and others are being trained for this service. Throughout all Japan, it is said, the women have caught the war fever, and the greatest enthusiasm prevails. A number of women of high rank have offered to go to the seat of war as volunteer nurses, and others have even offered to raise a corps of female soldiers.

A Quick Answer.—A correspondent sends us a story told of an old country doctor down East. In the latter years of his life his ankles became very weak, necessitating the wearing of a pair of steel braces. One day, as the old gentleman was shuffling along on Exchange Street in Bangor, Me., some young wag called out: "Hi, doctor, hi, you are interfering!" "Not with other folks business, young man!" retorted the doctor.

Yellow Fever of a malignant type is reported to be epidemic in the coast regions of Nicaragua.

Traction on the Tongue in Hysteria.—Th. Balade (*Gaz. des Hôp. de Toulouse*, July 28th) has in two cases made very violent hysterical attacks cease by traction on the tongue, the organ being drawn with some force out of the mouth, and kept in that position for some minutes. This procedure was successful when every other treatment had failed.

Dr. S. Hembury Smith died on September 12th, in Brooklyn, N. Y. He was born in England in 1810, and was graduated in London in 1831. He studied later and practised in Stockholm; he came to this country in 1847, settling in Cincinnati. He afterward came to New York, where he was engaged for a number of years in the manufacture of artificial mineral waters.

To Celebrate the Discovery of Anæsthesia.—Mr. Charles J. Wells, of Hartford, is announced to be the only living descendant of Dr. Horace Wells, the discoverer of anæsthesia. He is said to be taking a deep interest in the arrangements now in progress for celebrating the fiftieth anniversary of his father's great contribution to surgical practice. Mr. Wells has been consulted by the committee from the Connecticut Dental Association, which has charge of the arrangements in this city, and is in complete accord with the project for a bronze tablet to be placed on the site that was occupied fifty years ago by the discoverer's office.

What a Maniac can Stomach.—One of the medical officers of the County Asylum, Lancaster, contributes to *The Lancet* an account of an operation upon a lunatic from whose incoherent statements it was suspected that he had swallowed some nails. Forceps passed into the stomach having failed to extract any foreign bodies, though they could be felt from the outside; it was decided to attempt to relieve the man by operation. On incision, the stomach was found to be occupied by a mass of rusty nails, many of them nearly three inches in length, and some very sharp, bent, and twisted. Their removal, naturally, was very tedious, as many of them could only be extracted one at a time. A piece of matted hair, nearly two inches in length, was also found. In all, there were removed from the stomach one hundred and ninety-two nails (the majority being two and a half inches in length, and many even longer), half a screw-nail, a piece of brass wire, a carpet tack, several small pieces of stick, a button, and the mass of hair already mentioned. The whole weighed one pound nine and one-half ounces. Several pieces of wood were found in the patient's intestines, but no nails.

The Country Doctor and Post-Graduate Study.—The editor of the *Post Graduate* has made an interesting analysis of the place of residence of three thousand eight hundred and twenty-four matriculates of the New York school. The students were divided into four classes, according as they came from large cities, having a population of over one hundred and fifty thousand; medium cities, having a population of over twenty-five thousand; small cities, having a population of over ten thousand; finally towns and villages. We find from the figures that have been furnished us that there is a pretty even distribution of matriculates in all four classes. The towns and villages, however, rank at the bottom with six hundred and ninety-five students, while the medium cities are at the top of the list with eleven hundred and four. On the whole, one can see that it is the medium cities and large towns that furnish the greater number of matriculates. The number from the large cities is relatively small. Another interesting fact which is developed by the study of tables is this: The physicians from the towns and villages are coming to us in increasing number every year. During the first four years of the school, not more than twenty-five or thirty came from this class, but in the last year or two the numbers have exceeded one hundred, and last year the villages and towns of the United States furnished as many students as the large cities.

This, adds the editor, is certainly an interesting, and we would add a hopeful, sign. It shows that the doctors in the smaller places are making a living, and a little more, and what is still better, it shows that they possess a desire to keep abreast of the times, and that this desire is even keener than that which the city physicians have; for it must be remembered that it requires no small sacrifice for a country doctor to leave his practice, turning over his patients to the care of a brother physician with whom his relations may, perhaps, have been sometimes a little strained, and of whose experience and skill he has, perhaps, himself once expressed a slight amount of doubt. But it is evident that a country doctor is bound to learn, and that he is learning and is keeping as alert in every direction as his city brother.

The Late Dr. Albert B. Miles, House Surgeon of the Charity Hospital of New Orleans, left $10,000 each to the following institutions: Medical Department Tulane University of Louisiana; Charity Hospital of New Orleans; and the Hotel Dieu, also of New Orleans.

Fighting the Diploma Trade.—Dr. C. T. Metcalf, Secretary of the Indiana State Board of Health, has instructed the county boards of health to notify clerks of court to refuse licenses on the diplomas of the "Marion Physico Medical School of Indiana and Marion."

Physicians' Protective Association.—The first annual meeting of the Physicians' Protective Association of Detroit was held September 4th. Reports of officers showed a prosperous year, $9,916 in outstanding accounts having been collected. Officers for the ensuing year were elected as follows: *President*, Dr. L. J. Lennox; *Vice President*, Dr. R. H. Stevens; *Secretary*, Dr. P. M. Hickey; *Treasurer*, Dr. S. H. Knight.

The Office of Coroner to be Abolished.—The Constitutional Convention at Albany has adopted the first amendment abolishing the office of coroner in this State as a constitutional office. The purpose of the amendment is said to be to make it possible for the Legislature to provide that only physicians shall exercise the duties now performed by elected coroners.

The Medical Society of the Missouri Valley held its seventh annual meeting in Council Bluffs, Iowa, on Thursday, September 20th. The programme contained the titles of twenty-five papers presented by members of the Society from Missouri, Iowa, and Nebraska. Dr. A. F. Jonas, of Omaha, was President, and Dr. F. S. Thomas, of Council Bluffs, Secretary.

Obituary.

BEAVEN NEAVE RAKE, M.D.,

TRINIDAO, WEST INDIES.

With profound regret we notice the death of Dr. Beaven Neave Rake. A cablegram received in London announced the sad event. He died in Port of Spain, Trinidad, British West Indies, August 24th, of fever—presumably, yellow fever, as it has prevailed there in epidemic form for several months past.

Dr. Rake was one of the world's recognized specialists in leprosy. He had made its study the work of his life. *The Lancet*, London, September 1st, referred to him as having been "one of the greatest authorities" on that disease.

Ere entering on the study of medicine and surgery he had received a thorough classical education. He became a member of the Royal College of Surgeons of England in 1879, a Licentiate of the Royal College of Physicians of London in 1880, a Bachelor of Medicine, University of London, 1881, and a Doctor of Medicine of the same in 1882. He had had seven years' hospital experience in London, one year on the Continent, one year in the East Indies, studying leprosy, and nearly ten years as Chief Medical Officer at the Trinidad Lepers' Asylum.

He was a member of the Pathological Society of London, the British Medical Association, Pan-American Medical Congress, Washington, 1893, Trinidad Medical Society, etc., etc.

He was a faithful and indefatigable worker, a man of keen perceptive powers and sound judgment. His early training had eminently fitted him for the government appointment at Trinidad. He was an able and prolific writer. His original observations have been published in England in *The Lancet*. In America the Medical Record published his last paper—being a concise summary of his observations. That paper, specially prepared, appeared in its columns a few months ago.

All students of leprosy will remain profoundly grateful for the veritable "arsenal of facts" that he has left on record. His name will ever rank as an original worker and thinker.

While on the Anglo-Indian Commission he and his associates examined the histories of over two thousand cases of leprosy; in but two instances could contagion have been a factor; sensationalism in medicine he deprecated. For twenty-eight years past the Sisters of Charity have had exclusive charge of the Trinidad Lepers' Asylum; not an instance can be cited where they have become infected.

At the Pan-American Medical Congress he read a paper on leprosy before the Section on Dermatology, and addressed the Sections of Hygiene and Climatology on the same.

Death, in selecting him at the early age of thirty-six, has taken from us a bright and shining light; but "his good works will live after him." He died like a brave soldier, fighting disease during an epidemic. He had warm friends the world over. The warm shake of the hand, the frank, manly glance of the eye, will be remembered. He was one of God's greatest works—"a true man." His genial manners and quiet dignified way have left a living impress on his time and profession. He leaves a widow and three little sons. The highest compliment that can be paid a member of our profession is his first due—"He did his duty."

A Comfortable Ailment Desired.—Lady medicals are at times hard pressed for patients, as the following little wail will show: "Wanted—the care of an invalid lady of means (comfortably ill), who will appreciate best of medical skill and competent nursing; with kindly, sympathetic attention. Address Lady Physician, Herald Agency, 708 Columbus Av."

Clinical Department.

TABES DORSALIS IN A WOMAN TWENTY-THREE YEARS OLD.

By L. PIERCE CLARK, M.D.,

MIDDLETOWN, CONN.

This case of tabes dorsalis in a woman but twenty-three years old, came under my observation when I was house physician at the workhouse hospital, on Blackwell's Island. She was admitted to the hospital and remained there for four weeks, during which time she made little or no improvement.

Five years previous to her admission she contracted syphilis in a very severe form, and its treatment was almost entirely neglected until the tertiary symptoms made their appearance, when she took the baths at Hot Springs, Ark., for six months. But they gave her little relief. For seven years she had used alcoholic stimulants, taking sometimes twenty or thirty drinks a day. The remainder of her history is as follows:

Name A. D——; aged twenty-three; single; had been a prostitute for six years; family history good. She had never been sick before her present illness; at least not sufficient to incapacitate her for her abnormal occupation. The present attack began about eight months prior to her admission to the hospital. After one of her usual debauches, lasting four days, she complained of faint and dizzy sensations, which came on every three or four days, and lasting only an hour or so. These attacks gradually increased until they were of almost daily occurrence, lasting three or four hours each time.

One month from these first symptoms of dizziness, etc., vomiting and sharp lancinating pains in the epigastrium began. The vomiting was projectile in character, and the pains in epigastrium radiated from a central point in all directions, especially toward the vertebral column. This attack was also attended by purging. It lasted for two days, during which time she was obliged to remain in bed. Notwithstanding the severity of the attack she recovered, so as to be about on the third day, and was as well as ever, save the faint and dizzy sensations which continued to trouble her greatly, when she had taken considerable exercise. For the next five months she used stimulants very freely.

At the time of her admission to the workhouse on the charge of "soliciting," she had the appearance of one who had been suffering from syphilis and the abuse of alcohol for a long time, although she was in fair physical health. She was unable to walk to any great extent, and complained constantly of sharp, darting pains in legs, inability to see clearly, and occasionally saw double. These eye symptoms had been more or less prominent for past two months.

Physical examination revealed entire absence of knee-jerk, immobility of pupils, the right being a little larger than the left. The girdle sensation was present around upper and lower abdomen. There was swaying on standing and the gait was markedly ataxic. There was also present some inco-ordination of upper extremities. The feet were numb and cold, and the cutaneous sensation to pin-prick was perceptibly delayed and diminished over lower extremities.

On her discharge her symptoms remained about the same, except the gait, which showed some improvement, probably because the alcohol had nearly all left the system.

This case was diagnosed on admission as one of alcoholic neuritis, because of her alcoholic condition at the time of her arrival at the workhouse, and the subjective symptoms. But upon obtaining a syphilitic history, and the presence of the effects of syphilis yet remaining, together with the absence of a great many of the symptoms found in alcoholic neuritis, such as diminished motor power, tenderness along course of nerves, and

atrophy of any of the muscles, we had sufficient evidence to cause a more careful inquiry into the case, which resulted in the above diagnosis of tabes dorsalis. No mental symptoms were present.

It is just possible that a peripheral neuritis of alcoholic origin was present in this case together with tabes.

The early vomiting, pains in epigastrium, and purging which came on without any apparent cause and disappeared entirely in two days, seems to me to be a form of visceral crisis quite frequently found in tabes. I think the case is one of considerable interest, as it is an instance of tabes dorsalis in a young woman but twenty-three years old.

Her after history is unknown, as she passed from under my observation after leaving the hospital.

REMARKABLE USE OF BICARBONATE OF SODIUM.

Dr. Robert G. Feek, of Hamilton, N. Y., writes: "William G——, who resides in the town of Dekalb, near Hamilton, St. Lawrence County, N. Y., was suffering from disease of the stomach about twenty-five years ago. He states that he spent all his earnings in doctoring till about twenty-one years ago, when he tried saleratus, which gave him relief. Since then he has used it constantly and is now using the twenty-second hundred pounds. He carries it with him wherever he goes. He is sixty one years of age, father of eleven children, and does all the work of a farm of one hundred and ten acres except an occasional extra help. He purchases his saleratus by the barrel. These statements are authentic, as inquiry will prove. The saleratus is taken in a dry state. At first it was taken in small quantities, but now in doses of one-half ounce, and to the quantity of over two pounds a week."

A FOREIGN BODY IN THE EYE FOR SIX YEARS.

By THOMAS M. STEWART, M.D.,

CINCINNATI, O.

Cases of foreign bodies in the eye are interesting to eye surgeons, because of the many important questions that they involve. The case herewith reported is interesting because of the length of time the foreign body was retained, with the history of pain and redness, and absolutely no irritation occurring in the sound eye.

The patient was a married man, aged forty years. Six years previous to his first visit to me, while watching miners at work, a piece of coal struck him in the right eye. He was at once removed to his home, and a surgeon summoned. After some weeks he was discharged from the surgeon's care, but with a blind eye. The iris was occluded, the small pupillary space presented to view a cataractous lens. Subsequently, the man sought medical aid for the relief of severe lightning like pains in the injured eye. The pains continued from time to time. I found the eye a little red, no pains on palpation of the ciliary body, but pressing the eye backward and a little outward, he complained of severe cutting pain. He was then taking morphine for the relief of the pain; he took several one-fourth grain pills every day, and when the attacks were very severe he took more.

From the history of the case, evidence of having been struck in the eye by a flying missile, the occluded pupil, cataractous lens, and the history of pain from the time of injury, I advised enucleation. Two days later he gave his consent, and the eye was removed in the ordinary way. Adhesions were cut away at the back of the globe. Section of the eye showed the adhesion of the iris to the opaque lens, and the vitreous was dark brown in color. Close to the optic nerve was found an enlargement, due to a piece of coal 6 mm. square, ragged at one end. This pushed the sclera backward, and had become firmly imbedded. A firm adhesion also held it to the nerve.

The question of enucleation had been considered, but it was thought that the pain was entirely neuralgic, coming in paroxysms aggravated by change in temperature and humidity of atmosphere. The sound eye had been interrogated for recession of the near point, and other symptoms of sympathetic inflammation. These points determined his medical advisers upon no interference.

To my mind there was no question as to the necessity for operation, it was a clear case for the rule to enucleate an eye subject to attacks of redness and pain, the vision of which has been destroyed by an injury.

THE SWALLOWING OF A HAT-PIN, AND ITS SUBSEQUENT EXTRACTION.

By THOMAS B. STEELE, M.D.,

CAMBRIDGE, MD.

I had yesterday, July 15th, the most extraordinary case of surgery I ever saw, or that has ever occurred in this part of the country.

About three weeks ago I was called in to see a colored child (female) a little over three years old. She complained of severe pain at the inner extremities of the two lower ribs of the left side. She kept her body constantly bent over to that side as far as she could get it, and a little forward. In this position she was somewhat relieved, but was never entirely free from pain. She had but very little fever, if any, and her appetite and digestion were fairly good.

About ten days ago a protuberance the size and shape of section of an ordinary hen egg, made its appearance just over the seat of pain. As her mother and the rest of the family insisted so strongly that nothing had occurred to account for her symptoms, I was forced to the conclusion that by some forgotten accident the cartilages at the enlarged spot had been dislocated from the ribs, or a growth of some kind, most probably an abscess, was forcing its way there to the surface. Last night I was sent for in a great hurry to see her, as the sharpened end of a hat-pin had made its appearance through the middle of the lump. And such I found to be the case. By slight pulling the pin would come out five or six inches, but was retained by its large bullet shaped end.

The pin penetrated the cartilage of the eleventh rib, instead of coming out between the ribs, where there was less resistance, and as nothing could be done without keeping her constantly under the influence of chloroform, and I could not do so unassisted, I sent for Dr. B. W. Goldsborough. After some difficulty he succeeded in enlarging the opening in the cartilage and in extracting the pin.

Last night her mother remembered that some children told her the child had swallowed, the day before she complained of being sick, a hat-pin, but she thought it so unlikely that it had escaped her memory. This morning she is more comfortable. Rather a large quantity of water flows from the opening, which shows that it connects with the stomach.

A Patient in one of the Paris hospitals was recently scalded to death in a bath through negligence of the nurse.

Breast Tumors in Women.—A "lump in the breast," previously to twenty five years, may often be "severely let alone;" one after thirty five can be disregarded only by the surgeon who is reckless to the verge of criminality.—Dr. Herbert Snow in *The Practitioner*, August, 1894.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

VACATION—CHOLERA PROSPECTS—THE OPIUM COMMISSION—THE REPORT OF THE LUNACY COMMISSIONERS—THEIR VIEWS ON BEER.

London, September 1, 1894.

London is just now more depleted of her doctors than during the brief meeting at Bristol, for a considerable number have set out on their autumnal holiday. In the few Bristol days we had scarcely time to miss them, for those who went—or a large proportion of them—returned to town before leaving for any length of time. The appearance of "students' numbers" of the journals is an indication that the opening of the winter session is only just a month ahead. Then the active teachers will be obliged to be at home, and even the fashionable consultants will begin to return.

We have passed the first of the two most dangerous months in respect to cholera; but September has several times been a month of invasion, and as the disease is still epidemic on the Continent the danger is obvious. Hitherto the weather has been in our favor, but there is now a prospect of hot, damp days, which, if long continued, may cause any seeds sown last year to spring up. Whether we are to escape altogether or suffer from such recrudescence, or to be invaded afresh is therefore a favorite topic of conversation and the speculations indulged in are sometimes more curious than instructive. After a long spell of cool, wet weather, the last two days have been hot, yet dull and misty. The ground in the country is no doubt saturated with moisture enough to give us a damp atmosphere as the sun pours down its rays. If cholera invade us it will therefore have a condition favoring its spread, and with all our sanitarians' efforts it is impossible to pronounce all our defences to be impregnable. The Local Government Board are prepared to act with energy. Inspectors are ready to visit suspicious cases, and provision is made for a bacteriological examination of fæces forwarded with a clinical record of the case. Expert advice and assistance is therefore at the disposal of those who may have to meet suspicious cases, and in the country the officers of health seem equally ready with help. If any port or sanitary authority should be caught napping the results may be disastrous, but we may still hope this will not happen.

The report of the Opium Commission will, I understand, not be issued until Christmas, but rumor is pretty busy as to its contents. Some persons profess to have precise information—others are evidently guided by their judgment of the evidence. The former say the report will be unanimous, and I hope they may be right, for that would probably deliver us from the "opium question" for some time to come. Both former and latter agree that the report will be conclusive against any interference by the state with the cultivation and use of opium. If so, it will be in accord with the evidence tendered by those medical men who have had the best opportunity of judging by their residence and official positions in India.

I may recur for a moment to the Lunacy Report, which I have previously noticed. In some quarters surprise is felt at the prepossession of the commissioners in favor of beer in the dietary. Again and again regret is expressed in the reports at the absence of beer or something else. Thus, respecting the Surrey Asylum, the remark, "workers only have beer," is evidently made in a deprecatory spirit. At Norwich it is remarked, "One gentleman complained of the stoppage of the dinner beer, which, we understand, has been general throughout the hospital." At Colney Hatch the commissioners observe, "Beer is not given to the workers, which we regard as a mistake, as it keeps down the percentage of employed patients." It is curious that encouragement should thus be given to the plan of inducing patients to work by paying them in beer. The commissioners defend their approval of intoxicating beverages thus: "The asylum is not a reformatory; and claiming to be advocates of temperance, which total abstinence is not, we think that the withdrawal from the temperate of their past life's beverage irritates, whereas every effort should be made to alleviate the morbid discontent of the sober patients, in proportion to whom the drunkards are few. These last, if in the incipient stage of their vice, so soon recover that they must be discharged too soon for the eradication of that vice; if they be old stagers, they come to the asylum wrecks of humanity, and their condition is too chronic for discharge, except through death. We deem it our duty to repeat our colleagues' objections in 1892 to what is in no sense a proceeding in the cause of true temperance, which is the avoidance of excess." I am not inclined to controvert this curious manifestation of the commissioners' penchant, nor would I go so far as to assert that a glass of small beer would have an appreciable effect on the majority of the patients. But I cannot compliment the commissioners on their logic, and there are other issues involved, as there are also in the case of workhouses, as to which the beer question is continually cropping up. The rate-payers may object to provide this luxury to persons who in large proportion owe their distress to too free indulgence in it. Then these very reports contain a series of tables, some of which show the predisposing and exciting causes of the patients' lunacy. As may be anticipated these statistics confirm those with which your readers are familiar, and prove the terrible rôle that alcohol plays in the production of insanity. I think the comissioners would find a difficulty in expounding these figures so as to support their views, which certainly do not seem quite up to date from a scientific point of view. It will therefore not surprise me if some controversy should be raised on the question.

WHO IS TO BLAME?

To the Editor of the Medical Record.

Sir: One of the great and much admired minds of the century has emitted the sentiments that,

> "Work without hope draws nectar in a sieve,
> And hope without an object cannot live."

After a fashion these lines were recalled to my mind by Dr. McGee's ardent letter published in to-day's Medical Record. The lines of the poet-philosopher can be applied to the evil complained of by Doctors Cochran and McGee, and many other good men, both as to its cause and its therapeutics.

Dr. McGee would have "one good general law" for limiting the number of medical colleges, and the number of medical colleges being limited by law, he would expect "a better satisfaction to the profession" to follow. Another blessing flowing from this law of numerical limitation would be, Doctor McGee says, "at least more than a show of real protection for the people." May one not ask why the "better satisfaction" of the profession needs the protecting hand of the lawyer? Law means lost innocence, lost manliness, and as a prohibitive help positive only by negation. What does "real protection for the people" mean? Is the profession becoming a band of beggars because this very profession in some sections of the country is developing medical schools and professors in superabundance? Quite the contrary. Those medical men who are impoverishing the profession by making it cheap, and who besides are committing a sort of wholesale homicide by inundating the public with medical humbugs very much after their own pattern find the business profitable. And while such business pays such men, can any other conclusion be drawn than that both the public (the people) and the profession rather like it? All things thrive by what they feed on, and the schools and the professors of whom complaint is made are no exception to this natural law.

The people who will have them deserve to have them. Why do these particular men hurry to establish schools and make themselves professors? It is because they hope to gain power thereby, and to turn that power and *éclat*—the prestige of a name—into money!

If they are not honorable men, they are ambitious and they are practical. They do not weave the cloth of gold from moonbeams. Their hopes are very material, and their object extremely selfish. They are not idealists. Indeed they resemble Napoleon I. in their hatred of idealists. Now the idea of professor is an actual idealism with the great body of the laity. It is not the legal conception. It is often an idealism that borders on the mythical. The professor of medicine (or surgery) to most layman is a man who knows when the practitioner does not know. The professor to the layman is the man who can do when the practitioner fails or is powerless. The professor to the layman is the man who has done his best to make the practitioner a capable man. The people have an ideal doctor in mind when they think of the medical professor. And it is this ideal that these would be medical schools and their would be professors deflower, and make the most of to their own selfish satisfaction. We must not be too hard in our judgments of the people just because a laudable ideal is theirs. The people are always right in the end, only it takes them such a long while sometimes to distinguish between brass and gold. Then, too, are not the better elements in and out of the profession parts of the people? The making of prohibitive laws, or agitating for them, are worthy ways of letting loose our altruistic and philanthropic propensities, when we do not forget our other and more important social and professional obligations. It is no more than just that every philanthropist, altruist, and ameliorist be the model he is clamoring for some one else to be. And besides clamoring for legislation—which is right in its way—each decent practitioner, as occasion offers, can do a good deal toward killing away the falsehoods on which the evils under consideration feed, by themselves emulating the lay ideal of the professor, and by teaching the laity who are and who are not not legal professors, but real and worthy professors. Perhaps decent and intelligent practitioners have contributed more than a mite toward the making of the layman's myths, and from which they feel ill effects every now and then.

ADOLPH RUPP, M.D.

NEW YORK, September 8, 1894.

HYDROPHOBIA STATISTICS DESIRED.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Will you permit me, through your columns, to ask that my professional brethren will communicate to me the occurrence of cases of so-called hydrophobia in their practice for the year 1894, from January 1, and so on until the end of this year?

I would like in all cases to learn: 1, The sex and age of patient; 2*a*, the kind of animal that is credited with the inoculation; 2*b*, its state of health; 2*c*, the provocation to bite (if any existed); 2*d*, the reasons why the animal was (if it was) deemed rabid; 3, the seat of the bite (or other mode of inoculation); 4, the fact and method of cauterization (if any); 5, the time between the inoculation and the outbreak; 6, the symptoms of the outbreak, the occurrence of mania or imitation of dog actions; 7, the remedies used and doses, with their seeming effect; 8, the issue of the case and when death occurred; 9, the investigations made to exclude the presence of disease other than so-called hydrophobia; 10, the findings on autopsy, if one was held.

I shall, of course, acknowledge in future publications aid received in continuing my studies in regard to this subject.

Yours respectfully,

CHARLES W. DULLES.

4101 WALNUT STREET, PHILADELPHIA, PA

"THE PHONOGRAPH; ITS PHYSICS," ETC.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: An article under the above title appeared in your issue for September 1, 1894, by J. Mount Bleyer, M.D., from which I quote the following: "Photographs and measurements of these tracings of the sound-waves on the wax cylinders, etc., were recently made by Herman, of the Königsberg Physiological Institute, and are of great interest in the study of the physics of sound." I desire to call attention to the fact that drawings and measurements of tracings of voice records upon a wax cylinder of a phonograph were made by me in 1888, and the same, with an article entitled "A Study in Physiological Acoustics—Preliminary Notice," were sent to your journal for publication.

The article appeared in the RECORD for November 17, 1888, p. 589, but the graphic representations were not published because you did not have space. In the article by me I state: "I have shown the number of vibrations to inch, entire length of letter or word, total number of vibrations to each, and also depth of imprint." If there was a disposition to credit our own countrymen for scientific research and investigation more, and less tendency to look abroad, it would be better for the profession and our country as well.

J. A. MALONEY, M.D.

1424 Q STREET, N. W., WASHINGTON, D. C.

A FALSE REPORT OF PREMATURE BURIAL.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Some time ago a patient handed me a slip cut from one of our daily papers, wherein was related, with the usual minute detail, a case of "Buried Alive." The incident was said to have happened near the town of Lester, Minn., and the victim was said, upon disinterment, to have been found completely turned upon the face, the flesh torn by the finger-nails, and the hands filled with hair torn from the head. As my patient was a lady of nervous temperament, who dreaded for herself or husband a similar terrible fate, I determined to run the lie to earth, and, accordingly, wrote to the postmaster, inclosing the slip, and asking him to report. The following is his reply:

LESTER, MINN., August 23, 1894.

DEAR SIR: In reply to your request will say, that I have taken time to thoroughly investigate the matter and find "*it is not true.*" It is true he was removed, but, he was found in the coffin the way he was placed there. I never heard of the matter until I got your letter.

Respectfully,

C. O. PERUSIS.

And that is all the foundation there was to this tale.

S. S. J.

A Simple Remedy for Cough.—Dr. Charles E. Page, of Boston, says that the best remedy for cough he has ever found is a teaspoonful of moderately hot water, taken every time a paroxysm of cough comes on.

Intra uterine Injections in Antiquity.—At a recent meeting of an Edinburgh medical society Dr. Ballantyne quoted from a paper by Dr. Koromilas, a Greek physician, in which it was claimed that there was evidence in the writings of Hippocrates, Oribasius, Paulus Ægineta, and Galen to show that these authors were acquainted with the use of intra-uterine injections. Hippocrates divided the generative organs into three parts—first, the external genitals; second, the genital organ or vagina; and third, the uterus. He also used for each a special kind of substance to be injected: wine with honey for the external genitals, goose grease for the vagina, and oil with honey for the uterus. Dr. Koromilas believed that Hippocrates was the first to make intra-uterine injections.

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 15, 1894.

	Cases.	Deaths.
Tuberculosis	98	108
Typhoid fever	26	13
Scarlet fever	17	2
Cerebro-spinal meningitis	0	4
Measles	14	3
Diphtheria	106	30
Small-pox	9	2

Unfortunate Fingers.—Dr. George Corrie, of Blossom Hill, Va., gives the following history, in the *Virginia Medical Monthly*, of a family of finger-losers: "George Williams, negro, had two fingers 'hurt by the cars,' necessitating amputation (by some other doctor than myself). His father is minus an index, I having amputated it after contact thereof with the proverbial 'buzz saw.' I have amputated the right *digitus auricularis* of one of George's nephews, the hand having been caught in an apple-grinder. I relieved another of George's nephews of his left *digitus auricularis*, the boy having fallen while carrying a sharp axe, the edge of which severed all tissues, artery, and nerve, and entered the first joint. All [illegible] time in the same house."

Taking His Telephone to Bed.—A Pittsburgh physician has devised a way of taking his telephone to bed, so that he can answer calls without rising. He has his telephone hung upon hooks in his office, the connections being made by the telephone coming in contact with an electric board which he has had constructed. He also has wires run to his bedroom, where another electric board has been placed. The doctor may be said to take his telephone to bed with him every night. He takes it from the hooks in his office, carries it under his arm up to his bedroom, and places it upon the hooks there. Should any calls come during the night, he can answer them without leaving his room, thereby getting the use of two telephones for the price of one.

Mor[illegible]m in Medical Men.—It is a fact—striking though [illegible]—that more cases of morphinism are met with among medical men than in all other professions combined. It is too true that a very large proportion of cases in general are found in our own fraternity. In a paper, "Opium Addiction among Medical Men," presented in the MEDICAL RECORD eleven years ago—June 9, 1883—reference was made to the dismissal within a week of a half-dozen doctors recovered from this disease, and attention called to the surprising frequency with which it occurs in this particular class. Another decade of professional work exclusively given to the betterment of such patients has brought no decrease in this number; indeed the reverse has quite steadily obtained, so that in a paper, "The Ethics of Opium Habitués," *Medical and Surgical Reporter*, September 8, 1888, in a *résumé* of 300 cases, we noted 118 doctors, and of 125 most recently under my care 62 were medical men; and the latest reference to my record shows a still larger proportion, being more than seventy per cent.—DR. J. B. MATTISON in the *Journal of the American Medical Association*, August 4, 1894.

Migraine in Infancy.—Intelligent observation and accumulating experience show that infancy does not escape many of the neuroses (perhaps we may learn to say none of the neuroses) observed in mature life. The diagnosis is obviously embarrassed by the difficulties attendant upon the elicitation of symptoms. Thus, it has been conclusively demonstrated that infants and young children may be unequivocally hysterical, and there is reason to believe that they may be similarly affected with migraine. Evidence in support of the latter proposition is furnished by the report by Dr. Betz of the case of a female infant, thirteen months old, that, at a time when influenza was prevalent, was seized with an attack of febrile gastro-intestinal catarrh, attended with diarrhœa. In the course of this illness the infant was seized with twitching, affecting principally the hands and arms, occurring intermittently and also during sleep. It further indicated by gesture its complaint of pain in the head. Consciousness was perverted, but not lost. It was observed that the child manifested a tendency to grasp the left side of its head and to lie upon its left side, and on examination the left side of the head was found to be somewhat smaller in size than the right, while further investigation disclosed the fact that an elder sister and

Diseases of the Heart in Typhoid, Scarlatina, Diphtheria.—Dr. Rhomberg points out that the parenchymatous and interstitial processes are not closely connected in the tissues of the heart. In typhoid the higher grade of parenchymatous degeneration advances rapidly to the end of the second week; but later this morbid change is not so great. Interstitial myocarditis, on the other hand, only makes its appearance at the end of the second week, when the parenchymatous has run its course. In scarlet fever the interstitial myocarditis may begin to make its appearance on the fourth day, but its intensity is not reached till the end of the second week. Diphtheritic myocarditis makes its appearance later than scarlet fever, usually about the seventh or ninth day, and its intensity is reached about the beginning of the third week, and is continued even into convalescence. Rhomberg has seen myocarditic bands from diphtheria in the third week. Leyden has recorded several in the fourth week well advanced. In typhoid, Rhomberg has met with these in the third week. The symptoms during the fever period are—great weakness of heart, irregularity and smallness of the pulse, probably with dilatation. The best sign of dilatation of the left ventricle with irregular contractions is, according to Leyden, galopp-rhythmus. Traube considered sudden sinking of the pulse "frequenz" an ominous sign in diphtheria. Leibermeister considered the pathological increase of tissue fluid, as œdema of the ankles, a dangerous symptom. Dilatation is frequently met with in typhus by the middle of the second week; observable by the soft and empty pulse. In diphtheria Rhomberg can only relate one case of dilatation occurring in the first week. On the other hand, he has found it after a few days in scarlet fever continuing two or four weeks.—*Medical Press.*

Intestinal Toxins.—Two cases were related at the Clinical Society recently, one by Dr. Lauder Brunton and Mr. Watson Cheyne, the other by Mr. Silcock, which illustrates well the important *rôle* played by the toxins developed by decomposition of the intestinal contents in some cases of intestinal obstruction. The first was one in which, after repeated attacks of appendicitis, a somewhat gradual obstruction developed without tenderness or local signs of recent inflammation. On laparotomy being performed it was discovered that the cæcum was matted and tied down by general adhesions, but not strangulated by a band. After separating the adhesions it became possible to squeeze the contents of the small intestines into the colon, showing that the constriction was removed. Before the operation the patient had been in a state of the most absolute collapse; after it he improved somewhat for a time, but soon again relapsed, and seemed as bad as ever, until, after discharging a couple of very offensive motions, his condition rapidly improved, and he recovered without any further trouble. Mr. Silcock's case was apparently one of acute obstruction from, or at any rate accompanied by, peritonitis. Laparotomy was done, but from the matting of the intestines it was impossible to discover the exact cause, or in fact the position, of the obstruction. Ultimately however, the distended small intestine was attached to the abdominal wall, and a large amount of offensive fæcal matter was drained away. In this case, also, the collapse was profound, so that during the operation he was thought to be dead; but after the discharge of the offensive intestinal accumulation rapid recovery took place, the natural action of the bowels was restored, and the wound healed, although apparently the only thing the operation did was to empty the bowels of their contents. These cases put in striking light the fact, which is perhaps not so constantly borne in mind as it might be, that the fatal results of intestinal obstruction are not entirely due to the local mischief at the seat of the block, the strangulation, the volvulus, or the intussusception, but depend largely upon the absorption by the intestines above it of the toxins produced by the decomposition of their contents. These symptoms of sapræmic intoxication are no doubt often absent, but where they exist, where with low temperature there is thready pulse and general failure, the emptying of the bowel may clearly be as important a means of saving life as the relief of the strangulation.—*The British Medical Journal.*

Prostitution in Berlin is increasing very rapidly. According to a recent report of a committee of the Berlin Medical Society, the members of the demi monde were estimated to number from 40,000 to 50,000. In 1886 the number of professional prostitutes, those recognized as such by the police, was 3,006, and this had increased in 1891 to 4,364.

Death of an Aged Priest.—A Greek priest died recently in Trikhala, Thessaly, at the reputed age of one hundred and twenty years. He had had charge of the

DIPTHERIA AND PSEUDO-DIPHTHERIA.

A REPORT TO HERMANN M. BIGGS, M.D., PATHOLOGIST AND DIRECTOR OF THE BACTERIOLOGICAL LABORATORY, ON THE BACTERIOLOGICAL EXAMINATION OF 5,611 CASES OF SUSPECTED DIPHTHERIA, WITH THE RESULTS OF OTHER INVESTIGATIONS ON THE DIPHTHERIA AND THE PSEUDO DIPHTHERIA BACILLUS. FROM THE BACTERIOLOGICAL LABORATORY OF THE HEALTH DEPARTMENT OF NEW YORK CITY.

BY WILLIAM HALLOCK PARK, M.D.,

BACTERIOLOGICAL DIAGNOSTICIAN AND INSPECTOR OF DIPHTHERIA, FELLOW IN PATHOLOGY, COLLEGE PHYSICIANS AND SURGEONS, COLUMBIA COLLEGE, NEW YORK,

AND

ALFRED L. BEEBE, PH.B.,

INSPECTOR OF BACTERIOLOGY,

NEW YORK.

FROM May 4, 1893, to May 4, 1894, there were 5,611 cases of suspected diphtheria subjected to bacteriological examination. In 3,255 of these the Loeffler bacilli (the bacilli of true diphtheria) were found to be present, and these cases were thus proven to be true diphtheria. In 1,540 no diphtheria bacilli were present in the cultures, and as these had been carefully made at an early period of the disease, the cases from which they were taken may be considered as proven not to have been true diphtheria. In 816 cases, although no diphtheria bacilli were found in the cultures, yet, for various reasons (either because they were made after the fourth day of the disease, or the exudate was imperfectly obtained from the throat, or the culture media had become contaminated or were too dry), the cases from which the cultures were obtained were considered to be of a doubtful nature, so far as the bacteriological examination was concerned, although they were probably not diphtheria.

Thus we find in 5,611 cases of suspected diphtheria that about fifty-eight per cent. were proven to be true diphtheria, twenty seven per cent. to be false or pseudo-diphtheria, and fifteen per cent. to be of somewhat doubtful character. It would probably be just to consider that sixty per cent. were true and forty per cent. were false diphtheria.

Sex, Age, and Mortality in the Cases of True Diphtheria.—In a large percentage of the cases the sex was given, and in these there were fifty-four per cent. females and forty-six per cent. males, a fairly even division. The statistics reveal some interesting facts as to the influence of age on the occurrence of true diphtheria, as well as on the mortality of the disease. The ages of persons attacked ranged between three weeks and seventy years. The ages and mortality were determined in 1,625 cases and were as follows:

Age.	No Cases	Mortality. Per cent.	Age	No. Cases.	No. Cases per Year. Average.	Mortality. Per Cent
1st 12 mos.	24		7th to 10th year	292	97+	15
2d "	109	45	10th to 15th year.	117	23+	5
3d "	233		15th to 20th year.	20	4	
4th "	258		20th to 30th year.	41	4+	20
5th "	192		30th to 50th year.	13	1⅔	
6th "	163	33	.....	.....	.....	..
7th "	163		.....	.....	.....	..
Total mortality in all cases						27

The number of cases increased with each twelve months of life up to the fourth year and then gradually diminished. The mortality was highest in the first two years of life, and then steadily diminished until adult life was reached, when it again slowly increased.

Scarlet fever was associated with diphtheria in about five of every thousand cases. Exact figures cannot be given.

Age and Mortality in False or Pseudo-diphtheria.—It has been the general rule of the Department to take no further cognizance of cases of false diphtheria after the culture has demonstrated the absence of the diphtheria bacilli.

In order, however, to compare the mortality and the communicability of false diphtheria with that of true diphtheria, 450 cases of the false were carefully investigated by sanitary inspectors detailed for this work. These cases comprised 300 occurring in the fall months and 150 occurring in the following spring. The cases were taken in consecutive order and are believed to be average cases.

Age.	No. Cases.	No. Deaths.	Mortality. Per cent.	Age.	No. Cases.	Average per Year.	No. Deaths.	Mortality. Per cent.

[1] Two deaths due to scarlet fever. [2] One death due to scarlet fever. [3] One death due to scarlet fever.

In the 450 cases investigated there were 11 deaths, or about two and one-half per cent. mortality. Of the 450 cases 42 were complicated by scarlet fever, and of these 42 4 died. In six of the 450 cases measles occurred as a complication, and these all recovered. Of the two deaths which occurred among the adults, one was of a man of seventy years who was suffering from a serious valvular lesion of the heart, and the other was of a young adult female* who died of septicæmia.

The five deaths occurring in uncomplicated pseudo-diphtheria in children under five years of age were all in cases in which the larynx was affected, and in three, more or less broncho-pneumonia developed as a complication.

True and Pseudo-diphtheria of the Larynx (*Membranous Croup*).—The statistics gathered of the location of the disease in the true and false cases are of special interest. There were 286 of the cases examined in which the disease was entirely or chiefly confined to the larynx or bronchi, and of these, 283 were in children and 3 in adults. In the cultures of 229 of the 286, characteristic Loeffler bacilli were found, and the cases were thus proven to be true diphtheria. Of the 229 cases in which the Loeffler bacilli were found, 167 showed no pseudo-membrane or exudate above the larynx, while in the remaining 62, although the larynx

*The history in brief of the second case was as follows: Three weeks before death the disease began with a swelling of one tonsil and its surrounding tissues. A week later, the tonsil was incised but no pus obtained, and about the incision a dirty brown pseudo-membrane formed. Later, the tonsil and surrounding tissue became necrotic and sloughed off, then the ulceration extended to the pharynx and the other tonsil, and was still progressing when the patient died of sepsis and exhaustion.

was mainly involved, there was also some membrane or exudate present on the tonsils or in the pharynx. In 57 out of the 286 examined, no diphtheria bacilli were found, but in 17 of these the cultures were unsatisfactory. Excluding the 17 doubtful cases, there were 40 cases of pseudo-diphtheria in which the diphtheria bacilli were certainly absent. The disease was confined to the larynx or bronchi in 27 of the 40, while more or less exudate or membrane was present on the tonsils or in the pharynx in 13.

TABLE OF RESULTS OF EXAMINATIONS OF CASES OF "MEMBRANOUS CROUP."

	Diphtheria Bacilli found.	Diphtheria Bacilli not found.
Cases in which the exudate was confined to the larynx or bronchi	167	27
Cases in which the exudate was chiefly confined to the larynx or bronchi, but other parts somewhat involved	62	13
Cases in which satisfactory cultures were not obtained	17	
Total cases examined	286	
Diphtheria	229	
Pseudo-diphtheria	40	
Doubtful	17	

We find, therefore, that of the cases of acute laryngitis in children which have been subjected to bacteriological examination in the laboratory of the Health Department during the past twelve months, about eighty per cent. have proved to be undoubtedly cases of diphtheria, and of the remaining twenty per cent. only fourteen per cent. were certainly not diphtheritic.

Not only have the bacteriological examinations shown that a large proportion of the cases of acute croupous laryngitis in children (commonly designated by the name membranous croup) are diphtheria, but the Department inspectors have frequently found that these cases were apparently the cause of characteristic pharyngeal diphtheria in others.

The comparatively small number of laryngeal cases examined is partially due to the fact that membranous croup has not been considered a contagious disease, and reports of such cases have not been required by the Health Department;* and partially to the custom of Department Inspectors to not make cultures in cases which have been intubated, or which seem so sick that the family may think injury had been done by inserting the swab in the throat. The cases in which no cultures are made are treated as cases of true diphtheria.

The Relation Between the Length of the Bacillus and Its Virulence.—Some investigators have believed the degree of virulence possessed by the diphtheria bacilli could, to a certain extent, be judged by their length. The longest bacilli were supposed to be the most virulent; those of medium length less so, and the shortest little, if at all, virulent. By observing this characteristic it was thought cultures might become helpful in prognosis. Very careful notes have been made on this point in the examination of the bacteria from the original serum tubes in 1,613 cases.

The results of the examinations are shown in the following table:

	Cases.	Mortality Per Cent.
Bacilli of average size found in	1,368	26
" longer than average found in	82	27
" shorter " " "	67	35
" short, not characteristic in shape and evenly stained, of which many were pseudo-diphtheria bacilli	66	12
Total cases examined	1,613	

The results obtained from this examination of 1,613 cultures therefore indicate that in New York the great majority of cases of diphtheria yield in cultures bacilli of medium size, which are characteristic in shape and manner of staining. In a moderate number of cases the bacilli found are much longer, and in about an equal number they are much shorter. Both the clinical histories and the animal experiments show that whenever in their shape and in the way in which they take the staining fluid the bacilli are characteristic, no information as to their virulence, either in men or animals, can be gathered from their length. Those bacilli, on the other hand, which are short and stain uniformly with methyl-blue, usually prove to be of the pseudo diphtheria type, and have no virulence in animals.

The Bacteriology of Diphtheria.—So many inquiries have been sent to the Department regarding the methods employed for the general bacteriological examinations of suspected cases of diphtheria, that it has been thought desirable to include in this report a condensed account of the facts which have been brought out in the various bacteriological investigations of diphtheria, together with a description of the characteristics of the diphtheria bacilli which must be known in order to make bacteriological examinations for diagnostic purposes.

It is hoped that with these additions this report may be of greater practical assistance to many who have begun or are about to begin similar work.

Successive Investigations Showing the Specific Causal Relation of the Diphtheria Bacillus of Klebs and Loeffler to Diphtheria.—In the year 1883, bacilli, which were very peculiar and striking in appearance, were shown by Klebs[1] to be of constant occurrence in the pseudo membranes from the throats of those dying of true epidemic diphtheria. One year later Loeffler[2] published the results of a very thorough and extensive series of investigations on this subject. He found the bacillus described by Klebs in most, but not in all, cases of throat inflammations which had been diagnosticated as diphtheria He separated these bacilli from the other bacteria present and obtained them in pure culture. When he inoculated these bacilli upon the abraded mucous membrane of susceptible animals, pseudo-membranes were produced, and frequently death followed. If a certain amount of a bouillon culture was injected subcutaneously into guinea-pigs, death was caused with characteristic lesions. Loeffler's failure to find the bacilli in every case examined is now explained by the fact that certain varieties of pseudo-membranous inflammation not due to the diphtheria bacillus, such as occur especially in scarlet fever, were then wrongly considered to be true diphtheria.

In 1887,[3] further studies by Loeffler added to the proof of the dependence of diphtheria on the diphtheria bacilli. In 1888, D'Espine found the bacilli in fourteen cases of characteristic diphtheria, and proved them to be absent in twenty-four cases of mild sore-throats which, clinically, were believed not to be cases of diphtheria. In the same year, the first report of the results of the very important investigations of Roux[4] and Yersin was published, and the dependence of diphtheria on the diphtheria bacilli may be considered to have been established. Roux and Yersin found that diphtheria bacilli were present in all characteristic cases of diphtheria, and that these bacilli possessed the cultural and pathogenic qualities of those described by Loeffler. They found, too, when the bacilli were inoculated upon the healthy mucous membrane of the trachea of the rabbit, no result

* An Amendment to the Sanitary Code was adopted by the Board of Health on June 6, 1894, by virtue of which membranous croup is regarded as laryngeal diphtheria, and hereafter physicians will be required to report such cases to the Health Department.

NOTE.—Many experienced physicians still find difficulty in believing that cases in which the exudate or pseudo-membrane is entirely absent from the pharynx and tonsils are those of true diphtheria It is also often difficult to persuade parents that such cases are diphtheria, as, for instance, a child, age 1 five, subject to attacks of bronchitis and slight laryngitis, developed a croupy cough. For diagnostic purposes a culture was made and the diphtheria bacilli were found to be present. It was with the greatest difficulty that the parents could be made to consider the case a serious one and to quarantine the child. Under suitable treatment, on the fifth day the child seemed nearly recovered, and now the parents became sure it was not a case of diphtheria, stopped all precautions, allowed the child to go out, etc. A relapse followed, the laryngeal symptoms increased, and the child died in thirty-eight hours, of asphyxia, intubation being refused.

followed; but if the inoculation was made on the abraded membrane, phenomena occurred which strikingly resembled those present in membranous laryngitis in man, *i.e.*, congestion of the mucous membrane followed by the formation of a pseudo membrane, œdematous swelling of the tissues, and of the glands of the neck, dyspnœa, stridulous breathing, and asphyxia. Injections of cultures beneath the skin of rabbits and guinea pigs in sufficient quantity caused their death in from thirty six hours to five days, the period varying in ratio to the susceptibility of the animal, and the number and the virulence of the bacteria introduced. The same results followed the injections of filtered cultures, showing the products formed by the growth of the bacilli were by themselves capable of causing the general lesions.

Roux and Yersin were also able to produce in animals characteristic diphtheritic paralysis. They produced this in many cases where the inoculated animals did not succumb to a too rapid intoxication. Paralysis commenced in a pigeon three weeks after the inoculation of the pharynx, and after all membrane had disappeared and the animal seemed to have completely recovered. In rabbits, the paralysis usually commenced in the posterior extremities, and then gradually extended to the whole body, causing death by paralysis of the heart or respiration. In rare instances the muscles of the neck or of the larynx were first paralyzed, and thus characteristic symptoms were caused. The authors conclude: "The occurrence of these paralyses, following the introduction of the bacilli of Klebs and Loeffler, completes the resemblance of the experimental disease to the natural malady, and establishes with certainty the specific *rôle* of this bacillus."

Finally, the microscopical changes in the internal organs of animals dying of experimental diphtheria produced by the bacilli have been shown by Welch and Flexner,[8] and by Babes [9] and others, to be essentially the same as those produced by diphtheria in man, and thus a still further proof is afforded of the specific *rôle* of this bacillus.

The results of the various observations detailed above have since been confirmed by a great number of combined clinical and bacteriological investigations, so that all who have studied the bacteriology of diphtheria would now agree with the following statement made by Welch [7] in an address on diphtheria: "All the conditions have been fulfilled for diphtheria which are necessary to the most rigid proof of the dependence of an infective disease upon a given micro-organism, viz., the constant presence of this organism in the lesions of the disease, the isolation of the organism in pure culture, the reproduction of the disease by inoculations of pure cultures, and similar distribution of the organism in the experimental and in the natural disease. In view of these facts, we must agree with Prudden,[6] that we are now justified in saying that the name diphtheria, or at least, primary diphtheria, should be applied, and exclusively applied, to that acute infectious disease usually associated with a pseudo-membranous affection of the mucous membrane, which is primarily caused by the bacillus called the bacillus diphtheriæ of Loeffler."

Pseudo or False Diphtheria.—Under this general title are included all cases of pseudo membranous or exudative inflammation of the mucous membranes in which the diphtheria bacillus is absent. The thorough consideration of the bacteriology of this form of inflammation is to be reserved for a later report, but it is necessary to touch on a few points here.

Since Loeffler [2] in 1889 first described a class of pseudo-membranous inflammations of the throat in which the diphtheria bacilli were absent and cocci present, it has been established that a certain proportion of the inflammations of the respiratory mucous membranes, which closely resemble the less characteristic cases of diphtheria, are not due to the diphtheria bacilli but to cocci, especially to streptococci.

It has been found that streptococci are commonly present in the throats of healthy persons, or at least in the throats of persons living in large cities, and that other forms of cocci, especially the pneumococci and staphylococci, are apt to be associated with them. These germs seem to live in the throat without creating any disturbance there so long as the mucous membranes are healthy, but under certain conditions, as when the mucous membrane has been made vulnerable by exposure to cold or other deleterious influences, or by the poison of scarlet fever, measles, or some other disease, the streptococci, alone or associated with other cocci, are able to attack the mucous membrane and to cause an inflammation. This may be of any degree of intensity from a simple inflammatory hyperæmia to an inflammation with the extensive production of pseudo membrane or with ulceration. Such inflammations, when associated with the formation of a pseudo-membrane, are known as pseudo-diphtheria. The exudate, or pseudo membrane, in pseudo-diphtheria is usually confined to the tonsils, but other parts, such as the larynx, pharnyx, and nostrils, may be invaded.

It has been found that the percentage of mortality in these cases is far less than in diphtheria, and that the disease is seldom, if ever, communicated to others.

The Proportion of Cases of Suspected Diphtheria which upon Examination Prove to be True Diphtheria.—As soon as careful investigation had demonstrated it was possible, with proper precautions, to separate by bacteriological examination the cases of true from the cases of false diphtheria, large numbers of cases suspected to be diphtheria were examined bacteriologically. The reports from hospitals in which all cases of diphtheria and of suspected diphtheria were examined, are of especial interest as showing the proportion of cases of true to false diphtheria. The results from these hospitals are all the more valuable because the cases came from all parts of the various cities in which the respective hospitals were located, and hence special local conditions were not likely to greatly influence the general results obtained. Thus Baginsky,[9] in Berlin, found the diphtheria bacilli in 120 out of 154 suspected cases; Martin,[10] in Paris, in 126 out of 200; Park,[11] in New York, in 127 out of 244; Janson,[12] in Switzerland, in 63 out of 100; and Morse,[13] in Boston, in 239 out of 400. Thus from twenty to fifty per cent. of the cases sent to diphtheria hospitals did not have diphtheria.

If we examine the reports of examinations made under some special conditions, as during an outbreak of some contagious disease in a hospital for children we find the results may differ in a striking manner.

Thus in 1889 Prudden [14] made bacteriological examinations of 24 fatal cases of pseudo-membranous inflammation of the tonsils, pharynx, and larynx. In none of these were the Loeffler bacilli found to be present. These cases occurred in two hospitals for children in New York, in which both scarlet fever and measles were at the time prevalent. During the past year we have examined the exudate from 46 fatal cases of suspected diphtheria occurring in the same institutions and found the bacilli present in 44 of them.

If scarlet fever and measles (but not true diphtheria) were prevailing in an institution, it is evident the bacilli would be absent from the pseudo membranes occasionally occurring in the throat as a complication of these diseases.

The Mortality in True Diphtheria and in Pseudo-Diphtheria.—All observers have found the mortality was far higher in those cases in which the diphtheria bacilli were present than in those in which they were absent. In true diphtheria the mortality has been found to vary from 25 per cent. to 70 per cent., while in pseudo diphtheria it varies from 0 per cent. to 20 per cent.

The death-rate in cases of pseudo-diphtheria occurring in hospitals averages far higher than the death rate outside of such institutions. The reason for this is chiefly to be found in the fact that it is mainly the graver cases, especially those suffering from laryngeal obstruction, which are removed to the hospitals.

Laboratory Technique. *Collection of the Blood-serum and its Preparation for Use in Cultures.*—A covered glass jar, which has been thoroughly cleansed with hot water, is taken to the slaughter house and filled with freshly shed blood from a calf or sheep. The blood is received directly in the jar as it spurts from the cut in the throat of the animal. After wiping the edge of the jar, it is covered with the lid and set aside where it may stand quietly until the blood has thoroughly clotted. The jar is then carried to the laboratory and placed in an-ice chest. If the jar containing the blood is carried about before the latter has clotted, very imperfect separation of the serum will take place. It is well to inspect the blood in the jar after it has been standing a few hours, and if the clot is found adhering to the sides, to separate it by a rod. The blood is allowed to remain twenty-four hours on the ice, and then the serum which surrounds the clot is siphoned off by a rubber tube and mixed with one-third its quantity of nutrient beef-broth, to which one per cent. glucose has been added. This constitutes the Loeffler blood-serum mixture. The broth used to mix with the serum is prepared as follows: One pound of finely chopped lean beef is allowed to soak in one litre of water in a cool place for at least twelve hours. The meat and fluid are now dumped into a cheese cloth or towel, and the fluid squeezed out. To this solution one per cent. of peptone, one per cent. of glucose, and one-half per cent. of common salt are added. It is well to test the reaction of the mixture, and if it is found to be acid, to render it neutral by adding a few drops of a solution of caustic soda or carbonate of soda. The whole is now boiled for half an hour, and filtered through absorbent cotton or filter-paper. If the broth is to be kept it should be placed in flasks and then sterilized. The Loeffler blood-serum mixture when ready is poured into tubes, which should be about four inches in length and two thirds of an inch in diameter. These tubes should first be plugged with cotton, and sterilized by dry heat at 150° C. for one hour. Care should be taken in filling the tubes to avoid the formation of air-bubbles, as they leave a permanently uneven surface when the serum has been coagulated by heat. To prevent this, the end of the pipette or funnel which contains the serum should be inserted well into the test-tube. About 2 c.c. are sufficient for each tube. The tubes having been filled, are now to be coagulated and sterilized. The tubes are placed at the proper angle and then kept for two hours at a temperature just below the boiling point. For this purpose a Koch serum-coagulator or a double boiler serves best, though a steam sterilizer will suffice. If the latter is used, a wire frame must be arranged to hold the tubes at the proper inclination, and the degree of heat must be carefully watched, as otherwise the temperature may go too high, the serum actually boiled, and the culture medium thus spoiled. After sterilization by this process the tubes containing the sterile, solidified blood-serum can be placed in covered tin-boxes and kept for months. The serum thus prepared is quite opaque and firm. A mixture of blood-cells renders the serum darker, but it is not less useful.

The Swab for Inoculating Culture-tubes.—The swab to inoculate the serum is made as follows: A stiff, thin steel rod, six inches in length, is roughened at one end by a few blows of a hammer, and about this end a little absorbent cotton is firmly wound. Each swab is then placed in a separate glass tube, and the mouths of the tubes are plugged with cotton. The tubes and rods are then sterilized by dry heat at about 150° C. for one hour, and stored for future use. These cotton swabs have proved much more serviceable for making inoculations than platinum-wire needles, especially in young children and in laryngeal cases. It is easier to use the cotton swab in such cases, and it gathers up so much more material for the inoculation that it has seemed more reliable.

For convenience and safety in transportation "a culture outfit" has been devised which consists of a small wooden box containing a tube of blood serum, a tube holding a swab, and a record blank. These "culture outfits" may be carried or sent by messenger or express to any place desired, and are kept at stations scattered throughout the city for the free use of physicians.

Directions for Inoculating Culture-tubes with the Exudate in Cases of Suspected Diphtheria.—The patient should be placed in a good light, and, if a child, properly held. The swab is removed from its tube, and while the tongue is depressed with a spoon it is passed into the pharynx (if possible without touching the tongue) and is rubbed gently but firmly against any visible membrane on the tonsils or in the pharynx, and then, without laying the swab down, it is immediately inserted in the blood serum tube, and the portion which has been previously in contact with the exudate is rubbed a number of times back and forth over the whole surface of the serum. This should be thoroughly done, but it is to be gently done, so as not to break the surface of the serum. The swab is replaced in its tube and both tubes, their cotton plugs having been inserted, are returned to the box and sent to the collecting station. The blank forms of report which accompany each outfit should be completely filled out and forwarded to the station with the tubes.

Where there is no visible membrane (it may be present in the nose or larynx) the swab should be thoroughly rubbed over the mucous membrane of the pharynx and tonsils, and in nasal cases, when possible, a culture should also be made from the nose. In little children care should be taken not to use the swab when the throat contains food or vomited matter, as then the bacterial examination is rendered more difficult. Under no conditions should any attempt be made to collect the material shortly after the application of disinfectants (especially solutions of corrosive sublimate) to the throat. If any of these instructions have not been carried out, the fact should be carefully noted on the record blanks.

The Examination of Cultures.—The culture tubes which have been inoculated as described above, are kept in an incubator at 37° C. for twelve hours, and are then ready for examination. On inspection it will be seen the surface of the blood-serum is dotted with very numerous colonies, which are just visible. At this time no diagnosis can be made from simple inspection. (If, however, the serum is found liquefied, or shows other evidences of contamination, the examination will probably be unsatisfactory.) A microscopical preparation is now made by placing a tiny drop of water upon a clean cover-glass, and then a platinum needle is inserted in the tube, and quite a large number of colonies are swept with it from the surface of the culture medium. The bacteria adherent to the needle are washed off in the drop of water previously placed on the cover glass and smeared over its surface. The bacteria on the glass are then allowed to dry in the air. The cover-glass is then passed quickly through the flame of a Bunsen burner or alcohol lamp three times in the usual way, covered with a few drops of Loeffler's solution of alkaline methyl-blue, and left without heating for ten minutes. It is then rinsed off in clean water, dried, and mounted in balsam.

In the great majority of cases one of two pictures will be seen with the $\frac{1}{12}$ oil immersion lens; either an enormous number of characteristic Loeffler bacilli with a moderate number of cocci, or a pure culture of cocci mostly in pairs or short chains (see photographs). In a few cases there will be an approximately even mixture of Loeffler bacilli and cocci, and in others a great excess of cocci. Besides these, there will be occasionally met preparations in which, with the cocci, there are mingled bacilli more or less resembling the Loeffler bacilli, but not characteristic. These bacilli, which may be either the less characteristic diphtheria bacilli or the pseudo-diphtheria bacilli (see photographs), are especially frequent in cultures from the nose.

In not more than one case in twenty will there be any serious difficulty in making the diagnosis, if the serum-

tube has been properly inoculated. In such a case another culture may clear up the doubt, or it may be necessary to obtain the bacilli in pure culture.

The Direct Microscopical Examination of the Exudate.—An immediate diagnosis, without the use of cultures, is often possible from a microscopical examination of the exudate. This is made by smearing a cover glass with a little exudate from the swab, drying, staining, and examining it microscopically. This examination, however, is much more difficult and the results more uncertain than when the covers are prepared from cultures. The bacilli from the membrane are usually less typical in appearance than those found in cultures, and they are mixed with fibrin, pus, and epithelial cells. They may also be very few in number in the parts reached by the swab, or bacilli may be met which closely resemble the Loeffler bacilli in appearance, but which differ greatly in growth and in other characteristics. When in a smear containing mostly cocci a few of these doubtful bacilli are present, it is impossible either to certainly exclude or make the diagnosis of diphtheria. Although in certain cases this immediate examination may be of the greatest value, it is not a method suitable for general use.

Characteristics of the Diphtheria Bacillus.—When cover-glass preparations made from the blood-serum tubes are examined, the diphtheria bacilli are found to possess the following characteristics:

The diameter of the bacilli varies from 0.3 to 0.8 m., and the length from 1.5 to 6 m. They occur singly and in pairs, and very infrequently in chains of three or four. The rods are straight or slightly curved, and usually are not uniformly cylindrical throughout their entire length, but are swollen at the ends, or pointed at the ends and swollen in the middle portion. Even from the same culture different bacilli differ greatly in their size and shape. The two bacilli of a pair may lie with their long diameter in the same axis, or at an obtuse or an acute angle. The bacilli possess no spores, but have in them highly refractile bodies. They stain readily with the ordinary aniline dyes, and retain their color after staining by Gram's method. With an alkaline solution of methyl-blue, the bacilli, from blood-serum cultures especially, and from other media less constantly, stain in an irregular and extremely characteristic way. The bacilli do not stain uniformly. Certain oval bodies, situated in the ends or in the central portion, stain much more intensely than the rest of the bacillus. Sometimes these highly stained bodies are thicker than the rest of the bacillus; again they are thinner and surrounded by a more slightly stained portion. The bacilli seem to stain in this peculiar way at a certain period in their growth, so that only a portion of the organisms taken from a culture at any one time will show the characteristic staining. In old cultures it is often difficult to stain the bacilli, and the staining, when it does occur, is frequently not at all characteristic.

Growth on Blood-serum.—If we examine the growth of the diphtheria bacillus in pure culture on blood serum we will find at the end of ten to twelve hours little colonies of bacilli, which appear as pearl gray or whitish gray slightly raised points. The colonies when separated from each other may increase in forty-eight hours so that the diameters may be a quarter of an inch. The borders are usually somewhat uneven. Those colonies lying together fuse into one mass, especially if the serum is rather moist. During the first twelve hours, the colonies of the diphtheria bacilli about equal in size those of the streptococci; but after this time the diphtheria colonies become larger than those of the streptococci, nearly equalling those of the staphylococci. The diphtheria bacilli in their growth never liquefy the blood serum.

Growth on One Per Cent. Alkaline Glycerine-agar, and Method of Obtaining Pure Cultures.—It is frequently desired to obtain the diptheria bacillus in pure culture. This is most readily accomplished by removing with a platinum needle a portion of the mixed growth of bacteria in a serum tube and lightly streaking it over the surface of the nutrient agar* contained in a Petri dish.

Though the growth of the diphtheria bacilli upon agar is less certain and luxuriant than upon serum, the appearance of the colonies when examined under the microscope is more characteristic.

If the diphtheria colonies develop deep in the substance of the agar, they are usually round or oval, and, as a rule, present no extensions, but if near the surface, commonly from one, but sometimes from both sides, they spread out an apron-like extension which exceeds in surface area the rest of the colony. When the colonies develop entirely on the surface, they are more or less coarsely granular, are nearly translucent, and usually have a darker centre. The edges are sometimes jagged, and frequently shade off into a delicate lace-like fringe; at other times the margins are more even and the colonies are nearly circular. With a high power lens the edges show sprouting bacilli (see photographs). The colonies are grayish or grayish white by reflected light, and pure gray or with olive tint by transmitted light.

The growth of the diphtheria bacillus upon agar presents certain peculiarities which are of the utmost practical importance. While the bacilli from the majority of cases grow rather feebly, some grow luxuriantly. If a large number of the bacilli from a recent culture are implanted upon a properly prepared agar plate, a certain and fairly vigorous growth will always take place. If, however, the agar is inoculated with the exudate of a throat which contains but few Loeffler bacilli, no growth whatever of the bacilli may occur; while the tubes of coagulated blood-serum inoculated with the same exudate contain them abundantly. Again, agar prepared from broth made from different specimens of beef, or to which different peptones have been added, varies somewhat as to its suitability for the growth of the bacilli. Because of the uncertainty of obtaining a growth by the inoculation of agar with a few bacilli, or with bacilli of diminished vigor, agar is a far less reliable medium than blood serum for use in cultures made for diagnostic purposes, and is therefore not to be recommended. All agar should be tested by means of a pure culture of the diphtheria bacillus before being used experimentally.

Growth in Broth.—All the varieties of the Loeffler bacillus experimented with have grown in slightly alkaline broth with or without the addition of one per cent. glucose. The characteristic growth is one showing fine grains. These deposit along the sides and bottom of the tube, leaving the broth nearly clear. In some cultures for twenty-four to forty-eight hours there is a more or less diffuse cloudiness, and exceptionally a film forms over the surface of the broth. On shaking the tube this film breaks up and slowly sinks to the bottom. All the varieties tested caused the alkaline broth to become acid, or, at least, distinctly less alkaline, within forty-eight hours.

Animal Inoculations as a Test of Virulence.—Animal experiments form the only reliable method of determining with certainty the virulence of the diphtheria bacillus. For this purpose alkaline glucose-broth cultures of forty-eight hours' growth should be used for the subcutaneous inoculation of guinea pigs. The amount injected may vary from one-fourth to one-half per cent. of the body-weight of the animal inoculated. In the great majority of cases, when the bacilli are virulent, this amount causes death within seventy-two hours. In the autopsy the characteristic lesions described by Loeffler are found; namely, at the seat of inoculation there is a grayish focus surrounded by an area of congestion; the subcutaneous

* The agar is prepared by adding one per cent. of agar to the required quantity of broth. This broth is prepared in the same way as that used in the blood-serum mixture already described, except that it contains no glucose. The agar must be thoroughly dissolved in the broth, and to accomplish this it is necessary to boil the mixture for from three to six hours. Before filtering, sufficient alkali must be added to make the agar slightly but distinctly alkaline. Finally, six per cent. of glycerine is added, and the mixture sterilized in flasks. When needed it is melted and poured into sterilized Petri dishes in a thin layer.

tissues for an extensive area around are congested, and at times very œdematous; the adjacent lymph nodes are swollen and the serous cavities—especially the pleural—frequently contain an excess of fluid, usually clear, but at times turbid; the lungs are usually congested. If the organs are subjected to microscopical examinations, the lesions described by Welch and Flexner,[5] Babes,[6] and others are found. There are numerous smaller and larger masses of necrotic cells which are permeated by leucocytes. The heart and the voluntary muscular fibres usually show degenerative changes. The number of leucocytes in the blood is increased. From the area surrounding the point of injection virulent bacilli may be obtained, but in distant areas and organs they are only ocasionally found.

Bacilli, which in cultures and in animal experiments have shown themselves to be characteristic, may be regarded as certainly true diphtheria bacilli, and as capable of producing diphtheria in man under favorable conditions.

Original Investigations.—A large portion of the daily work in the laboratory has consisted in the routine examination of the cultures received each day. Besides this, however, a number of important questions have been studied experimentally, of which the most important are the following:

1. How much reliance can be placed on the bacteriological diagnosis made from the examination of a culture inoculated with the exudations in the throat of a case of suspected diphtheria?

2. If in cultures bacilli are found which possess the shape, size, and staining characteristics of the diphtheria bacillus, can they, without further cultural or animal experiments, be considered as virulent diphtheria bacilli?

3. What is the period of time during which virulent diphtheria bacilli remain in the throat after the disappearance of the exudate or pseudo-membrane?

4. (*a*) What relation has the pseudo- and the non-virulent diphtheria bacillus to the true virulent bacillus?

(*b*) Are virulent diphtheria bacilli ever present in the throats of healthy persons who have been in contact with diphtheria?

5. To what degree is pseudo-diphtheria communicable?

6. What are the means by which diphtheria is transmitted?

1. *How much Reliance can be Placed on the Bacteriological Diagnosis made from the Examination of a Culture Inoculated with the Exudations in the Throat of a Case of Suspected Diphtheria?*—During the first few months, in order to test the results of the examinations and to make the liability to error as slight as possible, the following plan was adopted:

All cases in which the cultures yielded no diphtheria bacilli were turned over to special inspectors, who made, whenever possible, a second culture, and followed up the case during the illness, and for some time even after its recovery.

By means of the information thus obtained the bacteriologists of the Department were able more and more surely to decide how far they could base absolute diagnoses on cultures, especially when made by others. Many physicians, as well as the inspectors, gradually became so skilled in making inoculations that it was possible to rely certainly on the results obtained from the examination of their cultures; while, on the other hand, it was found that caution was necessary in accepting the inoculations of others, and in such cases a second culture was requested.

After a year's trial the following conclusions have been arrived at: The examination by a competent bacteriologist of the bacterial growth in a blood-serum tube which has been properly inoculated and kept for fourteen hours at the body temperature, can be thoroughly relied on in cases where there is visible membrane in the throat, if the culture is made during the period in which the membrane is forming, and no antiseptic, especially no mercurial solution, has lately been applied.

In cases in which the disease is confined to the larynx or bronchi, and where, therefore, there is no visible exudate against which the swab can be rubbed, surprisingly accurate results can be obtained from the examination of cultures, but in a certain proportion of cases no diphtheria bacilli will be found in the first culture, and yet will be abundantly present in later ones, the bacilli having probably been coughed up more freely as the disease progressed. We believe, therefore, that absolute reliance for a diagnosis cannot be placed on a negative result in a single culture from the pharynx in purely laryngeal cases.

In nasal diphtheria a negative result may be obtained from a culture made from the throat, and yet the bacilli be found in cultures from the nose.

In making a diagnosis from the examination of a culture it is essential to know the duration of the disease in the case from which it was made, because although bacilli may remain present and alive in some throats for many weeks, it is nevertheless important to remember they may vanish early and suddenly, and that, therefore, the cultures cannot be certainly relied on after the membrane begins to disappear.

The use of antiseptics shortly before making the inoculation of a culture tube may render the culture useless for diagnosis. It has been found in a few instances that a culture made from a case of diphtheria shortly after a thorough irrigation with a 1 to 4,000 solution of bichloride of mercury gave no diphtheria bacilli, though one made just before, and one made some time later, gave them abundantly. It is a curious fact that under such circumstances a vigorous growth of other organisms may take place.

The above conclusions are true only when the inoculations have been properly made, and in judging cultures received from physicians in general, the greatest care must be taken. Some cultures are made carelessly, and some evidently without taking the pains to even read the instructions, or to glance at the condition of the coagulated serum in the tube. If, therefore, when no diphtheria bacilli are found, the bacterial growth is scanty, the media dry or contaminated, or the inoculation in any way faulty, the case must be referred back for another culture. The second culture in these cases not infrequently contains the bacilli when the first did not.

The absence of the bacilli in a culture proves the case to be one of false diphtheria only when it has been possible to make it under the proper conditions.

2. *If in Cultures Bacilli are found which Possess the Shape, Size, and Staining Characteristics of the Diphtheria Bacillus, can they, without Further Cultural or Animal Experiments, be Considered as Virulent Diphtheria Bacilli?*—Since it is the custom in the laboratory of the Health Department to make a bacteriological diagnosis in suspected cases of diphtheria from the examination of the growth upon the original blood serum tube, without waiting for further cultural or animal experiments, it is of the greatest practical importance to ascertain to what extent bacilli appearing upon the serum in every way characteristic of the diphtheria bacilli can be assumed to be virulent.

To test the virulence of bacilli it is necessary to obtain them in pure culture, for otherwise it would be impossible to determine whether the changes produced in the inoculated animal were due to the supposed diphtheria bacilli or to other micro-organisms injected with them. It is further necessary to grow the bacilli in proper media and to inoculate susceptible animals at a period when the growth of the bacilli in the media has reached its maximum. It is only when these precautions have been followed that accurate results will be obtained. The present almost uniform practice is to inoculate half-grown guinea-pigs with from one-quarter to one-half per cent. of their body-weight of a forty-eight hours' culture of the bacilli grown at 37° C. in simple nutrient or glucose alka-

line broth. It is important to remember that it is not safe to decide because the growth derived from one bacillus is not virulent that all the bacilli from that throat are not virulent. The cultures from several bacilli must be tried. The majority of those who have inoculated bacilli derived from pseudo membranes and possessing the characteristics of the Loeffler bacilli have found, as Loeffler did, that they were always virulent. The researches of Hofmann,[15] Beck,[16] and others, however, showing that in a certain number of healthy throats there were bacilli which closely resembled the Loeffler bacillus and yet were not virulent, stimulated others to subject the bacilli from large numbers of cases of suspected diphtheria to the test of animal inoculation.

In 1890 Roux and Yersin[17] published the results of some examinations as to the virulence of the bacilli obtained from 100 cases of diphtheria. Fifty-five of these were fatal cases, and in all of them virulent bacilli were found, although in a few, together with many virulent bacilli, there were a few non-virulent ones. Among the 45 cases which recovered, many were very mild, and in 10 of them they found no bacilli of sufficient virulence to cause the death of guinea pigs, when injected in moderate amount. From all of them, however, they obtained bacilli capable of causing inflammation in the guinea-pig at the point of injection. This varied from slight, transient œdema to extensive necrosis. From further experiments they proved similar bacilli were able, under proper conditions, to regain their virulence. They further showed in these milder cases, among many non-virulent or slightly virulent bacilli, there were usually a few virulent ones; therefore they believed in most of these ten cases fully virulent bacilli may have been present in the throat with the slightly virulent ones, which by chance were used for the inoculations. In similar investigations carried on in a different locality somewhat different results were obtained. Escherich[18] was unable to obtain, from a large number of diphtheria cases studied, any bacilli having the characteristics of the Loeffler bacillus which were not virulent, and only a few which, in injections of one-quarter per cent. of the body weight of a forty-eight-hour bouillon culture, did not kill guinea-pigs within forty-eight hours. Koplik,[19] in New York, in testing the virulence of bacilli from mild cases of tonsillar diphtheria, found them in every case fully virulent.

In Baltimore Welch[20] and Abbott in eight cases of diphtheria found the bacilli in every case fully virulent. In a later investigation, in which a large number of healthy and slightly inflamed throats were examined, Abbott[21] found in the cultures from three, bacilli resembling the Klebs-Loeffler bacilli, but lacking virulence. These will be considered bacteriologically in connection with the pseudo diphtheria bacilli, but the cases are of sufficient interest to be briefly quoted in the present consideration of the virulence of bacilli obtained from throats in which inflammatory lesions have appeared which more or less resemble diphtheria.

Case I.—Adult, aged fifty-nine, while in hospital developed a laryngitis and pharyngitis. The uvula, tonsils, and faucial pillars became swollen and œdematous, of an intense crimson red color, and covered with a thin, grayish-white, slightly adherent exudate. In five days the patient completely recovered. Bacteriological examination showed abundant, apparently characteristic diphtheria bacilli, which, when inoculated, proved not to be virulent.

Case II.—Adult, similar lesions to last; well on ninth day. Bacteriological examination: Abundant bacilli, in appearance similar to Klebs-Loeffler bacillus, but not virulent.

Case III.—Girl, aged eleven; acute tonsillitis, with small white plug in one crypt. Quick recovery. Bacteriological examination: Apparently characteristic Loeffler bacilli, but not virulent.

It must remain a matter of doubt whether some colonies from these cases would have been found to possess virulence if more had been tested as to this characteristic. These cases, as well as those of Roux and Yersin, show that now and then the bacilli from cases suspected to be diphtheria have little or no virulence.

Original Investigations.—In order to determine the virulence of the bacilli obtained in the ordinary routine examinations from suspected cases of diphtheria, blood-serum cultures from twenty cases were selected in which bacilli were found having the characteristic appearance of the virulent diphtheria bacilli. The cultures tested were selected before any information was possessed of the severity of the case from which they were obtained and were used for experiments on animals.

Virulence of the Bacilli found in Twenty Cases of Throat Inflammations of such a Character as to arouse a Suspicion of the Existence of Diphtheria.

No.	Severity.	Weight of Guinea-pig. Gms.	Amount of Culture injected. C.c.	Duration of Life after Inoculation.	Persistence of Loeffler Bacillus after Recovery of Patient.
1	Very mild case. Sick only four or five days	458	2	40 hours	14–19 days.
2	Moderately severe case. Subsequently contracted scarlet fever	305	1	12 days.	
3	Mild case	350	1	45 hours.	24–32 days.
4	Mild case	900	3	40 hours.	
5	Mild case	405	1	40 hours.	6 days.
6	Very mild case. Culture taken after disappearance of membrane	430	1.5	40 hours.	13 days.
7	Very mild case	410	1.5	40 hours.	
8	Fatal case, and cause of severe case in mother	435	1.33	40 hours.	P. 16 days.
9	Mild case	390	1.33	40 hours.	P. 38–41 days.
10	Mild case. Adult; never in bed	210	0.5	50 hours.	P. 44 days.
11	Removed to Diphtheria Hospital. Severe case	220	0.5	40 hours.	
12	Rather mild case	620	3.33	25 hours.	P. 42 days.
13	Very mild case	479	2	40 hours.	P. 20–74 days.
14	Fatal case. Croup	675	1.5	40 hours.	
15	Fairly severe case, followed by measles	443	1.33	40 hours.	P. 15–23 days.
16	Moderately severe case	435	1.33	4 days.	P. 15–19 days.
17	Moderately severe case	510	1.66	40 hours.	
18	Fatal case. Croup	475	1.5	40 hours.	
19	Very mild case	500	1.66	40 hours.	
20	Contracted from a mild case. No membrane present	250	1	40 hours.	

We find, therefore, that the bacilli obtained from twenty cases of suspected diphtheria, two-thirds of which were very mild cases, proved in every case to be virulent, and in all but three fully so. If these results are considered in connection with those obtained by other American and European observers, we must conclude that for diagnostic purposes all bacilli found in throat inflammations suspected to be diphtheria, which possess the morphological and cultural characteristics of the Lœffler bacilli must be regarded as virulent unless animal inoculations prove otherwise. Further, it should be remembered (as shown by Roux and Yersin, and as confirmed by others and by ourselves) that the absence of virulence in a culture derived from one bacillus is not sufficient to prove that cultures from other bacilli from the same case would not be virulent.

In three of the above cases the cultures from the first colony selected were not virulent, while from others they were fully so.

3. *What is the Period of Time during which Virulent Diphtheria Bacilli Remain in the Throat after the Disappearance of the Exudate or Pseudo-membrane?*—If a piece of membrane be removed from a throat during the period of invasion of diphtheria and examined microscopically or by cultures, the presence of abundant diphtheria bacilli will be noted. If, a few days later, when the membrane has begun to loosen, another bit be examined the diphtheria bacilli will be found to be partly or at times wholly replaced by other micro organisms, mostly cocci. If, several days after the complete disappearance of the membrane, cultures be made from the mucus of the throat, it will be found the bacilli of diphtheria in many cases will have disappeared from the throat. This rule is not, however, without many exceptions, for it will be frequently found—days after the complete disappearance of the membrane and after the return of the

throat to a healthy condition—fully virulent bacilli linger in the throat.

If we examine the researches of others regarding this matter we find the following facts:

No.	Severity of the Diphtheria in the Case.	Length of Time during which the Bacilli had persisted after the disappearance of the Exudate when they were tested as to their Virulence.	Results obtained from the Inoculation of Guinea-pigs.
	Roux and Yersin:[17]		
1	Mild case.	3 days.	Guinea-pig died in twenty four hours.
2	Mild case.	3 days.	Fully virulent. Killed in a few hours.
3	Severe laryngeal case.	11 days.	Guinea-pig died in three days.
4	Severe case.	14 days.	Guinea-pig. Fully virulent.
5	Mild case.	9 days.	Some colonies virulent, some not virulent. For one week more, non-virulent bacilli were found.
6	Mild case.	7 days.	Virulent and non-virulent colonies. For four days more only non-virulent bacilli found.
7	Laryngeal case.	15 days.	On the twelfth day, all virulent. On the fifteenth, some virulent and some not virulent.
8	Severe case.	2 months.	Produced a slight local œdema only when injected into guinea-pigs. Fully virulent.
	Koplik:[19]		
9	Mild case.	14 days.	Virulent. A week later the bacilli obtained were not virulent.
10	Mild case.	7 days.	Fully virulent. (This was twenty-fourth day of the disease.)
	Loeffler:[22]		
11	Moderate case.	8 days.	

Escherich:[18] In a number of cases the Loeffler bacilli were found to persist after the disappearance of the membrane. In all of these the bacilli were as virulent as those obtained at the height of the disease.

Morse[13] in twenty-five cases found the average length of time the Lœffler bacillus remained in the throat after the disappearance of the membrane was ten days.

The average duration was the same for both nose and throat, although in some cases the bacilli were found in the throat much longer than in the nose, and *vice versa*. The bacilli disappeared in one case the day after the throat was clear, in another three days after, and in another four days after. The longest periods during which they persisted were twenty-two and twenty-seven days. The bacilli were tested from only one case, and these were fully virulent ten days after the disappearance of the membrane from the throat.

Tobiesen[23] found virulent diphtheria bacilli in the throats of 24 out of 46 patients at the time of their discharge from the hospital. The majority were children between six and twelve years of age. The following table gives the length of time after convalescence that the diphtheria bacilli were found:

Severity of Case.	Number of Cases.	Persistence of Bacilli after Disappearance of Membrane at Time of Examination at Discharge.
		Days.
Mild	1	4
Moderate	5	4
Moderate	4	5
Moderate	4	6
Mild	1	8
Moderate	1	8
Moderate	1	9
Severe	1	9
Moderate	1	10
Mild	1	10
Moderate	1	11
Severe	1	16
Moderate	1	22
Moderate	1	31
	24	214 Average, 8½

In the twenty-two in which the bacilli were not found the length of stay in hospital of the patients after convalescence was about the same. Tobiesen's studies indicate that the existence of throat lesions rendered the conditions more favorable for the persistence of bacilli. The virulence of the bacilli was proven in 19 out of the 24. In 16 cases the guinea-pigs died within a period of fifty hours, and the autopsies showed typical lesions; in 2, local necrosis developed, followed by death in one animal and recovery in the other. In the last case the animal developed paralysis five weeks after the local symptoms had disappeared. From these results he draws the following conclusions:

In 19 out of the 24 persistent cases the Lœffler bacilli proved virulent, and the probability is, they were also virulent in the 5 not tested. In other words, one-half of the patients who are allowed to leave the hospital under the usual conditions carry virulent bacilli in their throats, and are capable of giving diphtheria to others. Clinical investigation alone can decide the frequency with which these convalescent cases infect others. This investigation must be carried on with great caution. In the 24 investigated by Tobiesen he excluded those where numerous cases had occurred in the house besides the ones under investigation. Among those remaining he discovered one where the convalescent child was the almost certain cause of diphtheria in another.

Original Investigations.—In order to test the virulence of the bacilli in the throats of convalescent cases they were obtained in pure culture from the healthy throats of sixteen convalescent diphtheria cases and used for the inoculation of guinea-pigs. The following table gives the results of these experiments:

Case No.	Severity of Diphtheria in the Case.	The Bacilli Tested had Persisted after Recovery for—	Virulence.			Persistence from Inception of Disease.	
			Weight Guinea-pig. Gms.	Amount Injected.	Life of Guinea-pig after Injection.	Still Present.	Absent.
		Day		c.c.		Days.	Days.
1	Rather severe case.	8	392	1.33	60–70 hours.	13	17
2	Mild case	10	250	0.50	8 days.	12	19
3	Mild case	12	290	1.25	13 days.	.	..
4	Severe case	18	229	1.00	9 days.	21	30
5	Moderate case	6	549	1.25	14 days.	10	22
6	Mild case	33	226	1.00	Extensive necrosis with final recovery).	38	..
7	Very mild case.	12	440	1.50	40 hours.	14	22
8	Mild case	8	310	2.00	40 hours.	16	20
10	Very mild case.	25	505	1.66	40 hours.	30	..
11	Very mild case (nasal)	10	253	2.00	40 hours.	10	..
12	Mild case	6	490	1.66	40 hours.	24	..
13	Mild case	8	450	1.33	40 hours.	13	20
14	Mild case	12	367	1.33	40 hours.	19	..
15	Fairly severe case.	26	347	1.33	5 days.	35	44
16	Mild case	50	410	3.00	2 days.	56	..

In each case, in testing the virulence of the bacilli derived from it, we employed the last culture or the next to the last culture made from it in which the bacilli were found to be present. The results in the sixteen cases tested, as well as in those before recorded by others, prove conclusively that the bacilli, which in a certain proportion of cases persist in the throat after an attack of diphtheria, are always virulent for some time. In the exceptional cases in which the bacilli persist for a very long time, it is found they occasionally lose their virulence a few days before their final disappearance; while in other cases they retain their virulence to the end. That the cases themselves are not so liable to spread diphtheria is probably because of the relatively small number of bacilli present in convalescent throats as compared with the number found in those showing the lesions of diphtheria.

During the last year 2,566 cultures have been made from the throats of convalescent cases of diphtheria in order to determine the length of time during which the Lœffler bacilli persisted. The cultures were made at short intervals after the complete disappearance of the exudate, until the throat was found to be free of diphtheria bacilli. The custom was to make the second culture three days after the complete disappearance of the membrane, and then, when necessary, to make further cultures about every fourth or fifth day. Completed observations in 605 consecutive recovered cases give the following facts: In 304 of these 605 cases the diphtheria bacilli disappeared within three days after the complete disappearance of the exudate; in 301 cases the diphtheria bacilli persisted for a longer time, viz., in

176 cases for seven days; in 64 cases for twelve days; in 36 cases for fifteen days; in 12 cases for three weeks; in 4 cases for four weeks; in 4 cases for five weeks; and in 2 cases for nine weeks after the time when the exudate had to all appearances completely disappeared from the upper air-passages.

4. (a) What Relation has the Pseudo- and Non-virulent Diphtheria Bacillus to the True Virulent Bacillus? —In 1888 Hofmann published the results of the bacteriological examinations of a number of diseased and healthy throats, which for a time threw doubt on the specific character of the Loeffler diphtheria bacillus. Further research has entirely dispelled the confusion which his discoveries seemed to make, but the results of these studies and of similar ones on the virulent and non-virulent bacilli are of such practical importance in relation to the bacteriological diagnosis of cases of suspected diphtheria that a detailed account of the work of the subsequent investigators, as well as that of the Health Department, will be presented.

Hofmann's [15] results were similar to those of Loeffler, in that he found the virulent bacillus in all of eight cases of true diphtheria, but in further search he was surprised to find in the throats of twenty-six out of forty-five persons, none of whom was suffering from diphtheria, a bacillus which very closely resembled the Loeffler bacillus. Some of these persons were suffering from scarlet fever, measles, or some other disease, while many were entirely healthy. The bacilli from a number of these healthy throats were obtained in pure culture and inoculated into animals. The majority had no virulence whatever. The bacilli from the different cases varied somewhat in their characteristics. Some in appearance, manner of staining, and growth on media seemed identical with the Loeffler bacillus, while others presented slight but constant differences. Between the extremes were many gradations.

Those bacilli which did not possess all the characteristics of the virulent bacillus differed in the following respects: They were shorter, thicker, and more uniform in size. On agar they grew in whiter and thicker colonies whose circumference was more circular and less notched. They also grew at a lower temperature than the virulent bacilli (20° to 22° C.).

Hofmann was undecided whether all of these bacilli were really Loeffler diphtheria bacilli, which had lost their virulence, or whether they were a different species of bacteria and of a saprophytic nature. He was also undecided whether, even among these non-virulent bacilli, there might not be included different species. Hofmann's death prevented further attempts on his part to solve this problem, and different investigators since that time have been divided in their opinions; some taking the view that these bacilli were derived from true Loeffler bacilli, having merely lost their virulence; others that they were a different species, having no connection with the Loeffler bacillus; and still others consider the matter as undecided. The results of two other important series of investigations should be considered here, those of Roux and Yersin, and those of Escherich.

Roux and Yersin found in a hospital for children in Paris, where cases of diphtheria occurred from time to time, that fifteen out of forty five children contained in their healthy throats non-virulent bacilli resembling the Loeffler bacillus. In a French village where no diphtheria had been present for a long time they made cultures from the healthy throats of fifty-nine children living in a school. In twenty-six of these non virulent bacilli were found.

In an examination of the throats of ten attendants in a diphtheria hospital, non-virulent bacilli were found once. Thus, in one hundred and fourteen healthy throats the non virulent bacilli were found forty-two times. In all of these throats the bacilli were present in very small numbers. They found the same bacilli twice in six children with mild sore throats, and five times in seven children sick with measles. It should be noted that these examinations were made chiefly in a hospital and in a school, both for children, and in both of these the children were confined together for considerable periods of time, and the direct transmission of the bacilli from one throat to another would be likely to occur. The unusually large percentage of children in which they were found might thus be accounted for.

The bacilli found, when studied in pure culture, differed somewhat from each other. The majority were identical in all their characteristics with the Loeffler bacillus, except as to their lack of virulence. The minority resembles those described by Hofmann, being shorter and thicker and growing at a lower temperature than the characteristic Loeffler bacilli. They made the important observation that non-virulent bacilli, which they tested, when grown in broth, caused the same changes in the reaction as the virulent forms, namely, from alkaline to acid in forty-eight to seventy-two hours, and later back again to alkaline in the course of some weeks. These changes were found to occur even more rapidly in the cultures of the non-virulent than of the virulent bacilli. Roux and Yersin regarded the occasional slight differences in growth, shape, and staining, as too slight and inconstant to distinguish the virulent from the non-virulent bacilli. Animal experiments alone sufficed to determine the question of virulence, and they regarded as arbitrary a division founded on the reaction of the guinea-pig to inoculation; since they found bacilli from cases of diphtheria may possess every degree of virulence, from those which cause death within twenty-four hours to those which cause only a temporary œdema. With such variations it is a difficult matter to determine what should be the proper line of division between the virulent and the non-virulent bacilli.

To fully prove these bacilli belong to the same species they believe it is necessary to derive non-virulent bacilli from the virulent ones, and to give virulence to those entirely lacking it.

They found it was possible to produce an attenuation of the virulence of the bacilli in a number of ways. For instance, if a current of sterile air is kept passing through a broth culture of diphtheria bacilli, maintained at a temperature of 39½° C., after about two weeks some of the bacilli begin to lose their virulence, and at the end of about four weeks all of the bacilli have lost all of their virulence and produce non-virulent cultures. A little while after losing their virulence the bacilli remaining in the culture died.

They also found that if from time to time cultures were made from dried bits of membrane, a period finally came when the bacilli, although alive, had become non-virulent. Thus they had fulfilled the first condition.

The attempt to restore to bacilli the virulence which they had entirely lost was not so successful. They found it possible to greatly increase the virulence of bacilli by injecting them together with a virulent culture of the streptococcus of erysipelas. The bacilli obtained from animals which had succumbed to this double inoculation were found to have fully regained their virulence. Roux and Yersin were unable, on the other hand, to give back virulence to those bacilli which had been completely robbed of their virulence by the above methods, or to those which had no virulence originally when obtained from the throat. Thus of the two proofs necessary to establish the identity of the virulent and the non-virulent forms, they had obtained the first fully, the second only partially.

As additional proof of the identity of the virulent and non-virulent bacilli, they brought forward the fact that they found the latter more frequently in patients recently convalescent from true diphtheria than in those who had never had the disease, and that the bacilli which had artificially been deprived of their virulence frequently were changed in other respects, so as to resemble in all ways the bacilli which were originally lacking in virulence. From their studies they concluded the non-virulent and virulent bacilli were one and the same species of bacteria.

If we now turn to the work of Escherich we find results

which tend to show the virulent and some of the non-virulent bacilli are different species of bacteria.

He first lays stress on the methods to be employed in testing the virulence. He advises that the animal inoculations be made always from broth cultures, which have been grown for forty-eight hours at 37½° C., and that the amount of the culture be regulated by the size of the animal. Under these precautions he found the bacilli from every case of diphtheria examined to be fully virulent, and in a few cases, where he obtained characteristic bacilli from the healthy throats of persons exposed to diphtheria, he found them also to be virulent.

Escherich did indeed find in a moderate number of throats of persons not suffering from diphtheria a non-virulent bacillus similar to those described by Hofmann. Thus in Munich he found this non-virulent bacillus in 2 throats out of 70, and in Graz in 11 out of 250, or 13 times in 320 cases. These bacilli, however, all possessed certain cultural and morphological characteristics which were sufficient to separate them from the virulent bacilli. They were, as in some described by Hofmann, plumper and shorter than the Loeffler bacilli and more uniform in size. The growth on agar was more luxuriant and whiter than is the case with the diphtheria bacilli. He noticed two new points of difference which seemed to him important. The non-virulent or pseudo diphtheria bacilli, when spread on a cover-glass, lie in parallel rows, while the virulent diphtheria bacilli lie at every angle and in the most varied positions. The second difference was still more marked. He found, as had all others who had noticed this point, that the virulent bacilli in their growth in alkaline bouillon changed the reaction of the bouillon to acid in the course of forty-eight hours. The amount of acid formed differed in different cultures, and had no relation to the degree of virulence. He then noticed the pseudo diphtheria bacilli always made the bouillon more alkaline instead of acid. Therefore, if at the end of forty-eight hours litmus was added to the different bouillon-cultures it turned red in the virulent ones, and blue in the pseudo-diphtheritic non-virulent ones. Although this will be referred to again it should be noticed that this difference in reaction was not found by Roux and Yersin in the cultures of the non-virulent bacilli tested by them.

Escherich, in conclusion, states his position as follows: "Since we have found constant cultural differences between the true and the pseudo-diphtheria bacilli we can give the pseudo diphtheria bacilli no diagnostic value. We do not find it to be a frequent inhabitant of the mouth. Chronic throat inflammations and measles seem to render the throat more liable to its invasion."

He did not find, as Roux and Yersin and Fraenkel had, that it was possible to determine from the abundance of the colonies of bacilli present whether they were composed of virulent or non-virulent bacilli.

Up to the present time the results, so far as they are known to the writers, are given in the following tables:

	Von Hofmann.[15]	Loeffler.[3]
Morphology.	Some bacilli identical with those of Loeffler, others were shorter, thicker, and more uniform in size.	Somewhat larger than virulent bacilli, and more tendency to produce swollen ends.
Growth in bouillon and reaction.	Similar to virulent.	Similar to virulent.
Growth on blood-serum.	Sometimes identical with Loeffler bacilli; again found in larger and somewhat whiter colonies.	Similar to virulent.
Growth on agar.	Grows more luxuriantly and spreads more on the surface. May become of a dirty brown color in central part of colonies.	Colonies had less jagged edges and were of a whiter hue.
Frequency met with.	In 45 throats, comprising some healthy and some the seat of non-diphtheritic inflammations, they were found in 26.	Once with virulent bacilli from a case of diphtheria.
Opinion as to the nature of the bacilli.	Is doubtful whether these non virulent bacilli belong to the same species as the virulent diphtheria bacilli, or whether they are of a different species.	Believes them to be of a different species, but only to be separated by animal cultures.

	Escherich.[16]	Beck.[16]
Morphology.	Bacilli shorter, plumper, and more uniform in size. When a drop of bouillon-culture is smeared on a cover-glass the bacilli are found to lie in parallel rows.	Shorter, plumper bacilli as a rule, but some more like virulent bacilli.
Growth in bouillon and reaction.	More luxuriant growths, with tendency to cause cloudiness; when grown in neutral litmus bouillon the litmus turns blue after 2 or 3 days.	Quicker and more luxuriant in growth.
Growth on blood-serum.	Fairly characteristic, but apt to be a more luxuriant and whiter growth.	Somewhat more luxuriant and of a more yellow color.
Growth on agar.	Grows more luxuriantly and spreads more on surface; may become brownish in color after some days.	Colonies less jagged on margin and more yellow in hue.
Frequency met with.	In Munich in 2 out of 70, In Graz in 11 out of 250 healthy throats and those the seat of non-diphtheritic lesions examined. } 13 in 320	In 66 well children found in 22; in 41 non-diphtheritic affections in 14, or in a total of 107 found them in 36. Also along with virulent bacilli in true diphtheria.
Opinion as to the nature of the bacilli.	Believes that they have no relation to the virulent diphtheria bacilli, and that they can be separated pretty accurately by cultural differences.	Believed that the non-virulent forms found by him were of a different species from the virulent, and were saprophytic in nature.

	Koplik,[19] 1st Paper.	Koplik,[19] 2d Paper.
Morphology.	Short, plump, uniform in size. Take a more uniform stain.	Identical in form and size with virulent and characteristic stain.
Growth in bouillon and reaction.	More luxuriant, cloudy at first, afterward clearing, with abundant deposit; bouillon acid after forty-eight hours.	Cloudy; less abundant growth in bouillon to which glucose has been added; bouillon alkaline after forty-eight hours.
Growth on blood-serum.	More luxuriant and spreading.	More luxuriant, opaque, and whiter growth.
Growth on agar.	More luxuriant and spreading.	More luxuriant, opaque, and whiter growth.
Frequency met with.	In 4 mild throat inflammations.	In 2 following true attack of diphtheria. For first three weeks found virulent bacilli; then for two weeks there were non-virulent forms.
Opinion as to the nature of the bacilli.	Are of a different species from Loeffler bacilli.	

	Roux and Yersin.[4]	Abbott.[21]
Morphology.	Majority identical with virulent bacilli. The minority of shorter, plumper, and more uniform variety.	Bacilli from 3 cases were identical with virulent forms; from 1 they were larger than the virulent average.
Growth in bouillon and reaction.	Characteristic, except for slight cloudiness. Changes of broth were same as in virulent forms, but somewhat more rapid.	Growth in bouillon same as in virulent forms, except the changes from alkaline to acid, and later back again to alkaline were more rapid than in case of virulent bacilli.
Growth on blood-serum.	Same as in virulent.	Characteristic.
Growth on agar.	Same as in virulent, varying within the limits noticed in different virulent cultures.	Two of 4 characteristic, 1 more luxuriant in growth, and 1 giving colonies with darker central portion.
Frequency met with.	In 104 healthy children's throats found 41 times; 10 adults once. In 6 mild throat inflammations twice; in 7 sick with measles 5 times.	Four times in 53 throats. Some healthy, others the seat of moderately severe inflammations.
Opinion as to the nature of the bacilli.	Believed the non-virulent to be of the same species as the virulent; they were simply an attenuated form.	Non-virulent bacilli having all other characteristics of virulent bacilli to be of same species.
Note.		Pseudo diphtheria bacilli to show constant cultural differences.

	Fraenkel.[24]	Martin.[10]
Morphology.	Identical with virulent forms.	Short, plump bacilli.
Growth in bouillon and reaction.	Characteristic.	
Growth on blood-serum.	Characteristic.	
Growth on agar.	Characteristic.	More moist, luxuriant, and whiter. Grow at room temperature.
Frequency met with.	In number of healthy conjunctivæ and in some cases of mild tonsillitis, and with virulent bacilli in diphtheria. Figures not given.	In quite a number of diphtheria cases running a mild course.
Opinion as to the nature of bacilli.	Believes the virulent and non-virulent to be of the same species and includes under non-virulent, some causing local reaction.	An attenuated form of the virulent diphtheria bacillus.

If we review the remaining literature of this subject we find some investigators have been led by their results to adopt views similar to those of Roux and Yersin, others to those of Escherich, and still others have been forced to content themselves with the position of Hofmann, viz., that we are not yet in a position to affirm whether all these bacilli are of one or of different species of bacteria.

If we inspect closely the descriptions of the non-virulent bacilli, we find there seem to be two forms which stand out distinctly as separate varieties with which the others can be grouped:

1st. Bacilli which are in all respects, except that they lack virulence, identical with the Loeffler bacillus, and which, like it, produce an *acid* in their growth in broth-cultures.

2d. Bacilli which are shorter, plumper, and more uniform in size than the (characteristic) Loeffler bacilli, and which produce an *alkali* in their growth in broth-cultures.

As we look over the tables we see that some observers have chanced to find one of these varieties, some the other, and some both. This has led to the present confusion.

A COMPARATIVE TABLE OF NON-VIRULENT AND PSEUDO-DIPHTHERIA BACILLI.

	Non-virulent Diphtheria Bacilli.		Pseudo-diphtheria Bacilli.	
Case No. and Source.	New York, 66. (Throat.)	New York, 72. (Throat.)	Physicians and Surgeons, 30. (Throat.)	New York, 101. (Throat.)
Examination of bacilli in primary culture.	Abundant large characteristic diphtheria bacilli.	Abundant characteristic diphtheria bacilli.	Abundant short, even-stained bacilli. (See photograph of pseudo-diphtheria bacilli.)	Abundant short, even-stained bacilli (pseudo-diphtheria).
Growth in pure culture on serum at 37½° C.	Characteristic appearance of colonies.	Characteristic.	Fairly characteristic appearance of colonies.	Characteristic appearance of colonies.
Agar.	Fairly typical colonies.	Not typical colonies.	Coarsely granular colonies, with jagged, rough borders, and of about equal thickness throughout; brownish hue by transmitted light.	Fairly typical. More heavily pigmented and uniformly thicker than is characteristic of the virulent bacilli. Colonies nearly circular, with even borders.
Growth in neutral glucose broth.	Characteristic acid at end of forty-two hours.	Not characteristic. Broth cloudy for two days; acid at end of forty-eight hours.	Typical growth in rather coarse grains. Alkaline reaction at end of forty-eight hours.	Formation of thin pellicle and slight diffuse cloudiness. Alkaline reaction at end of forty-eight hours.
Virulence in guinea-pigs.	Guinea-pig, 216 gms.; 1.33 c. c. No reaction.	Guinea-pig, 164 gms.; 1.33 c. c. No reaction.	Guinea-pig, 405 gms.; 3 c. c. No reaction.	Guinea-pig, 400 gms.; 2 c. c. No reaction.
Clinical notes.	Bronchitis. Diphtheria in house three weeks previously.	Intestinal catarrh. No history of contagion.	Healthy throat.	Bronchitis. No history of contagion.
Sex.....	Female.	Female.	.....	Male.
Age.....	1 year.	15 months.	27 years.	10 years.

Original Investigations.—In order to study these various bacilli and to clear up, if possible, some of the questions connected with their classification, cultures were made upon blood serum from 330 healthy throats (children 280, adults 50).

When any of the varieties of bacilli described above were discovered in the cultures they were isolated, and in the great majority of cases tested, as to their virulence, on guinea-pigs. The results of these studies are given in the tables above. The bacilli formed may be divided into three groups.

1. Virulent Loeffler's diphtheria bacilli, characteristic in growth, producing acid in bouillon.

2. Bacilli identical with Loeffler's diphtheria bacillus in growth, producing acid in bouillon, but having no virulence.

3. Bacilli not having all the characteristics of the Loeffler bacillus in growth, producing alkali in bouillon, and having no virulence.

In the above table we find bacilli possessing the characteristics of the virulent diphtheria bacilli except that of virulence were found in 24 cases, namely:

Nos. 7, 33, 52, 63, 66, 72, 103, 105, 110, 114, 124, 132, 188, 189, 190, 191, 192, 193, 198, 212, 258, 259, 260, 297.

These bacilli were abundant in the primary cultures from 17 cases, and present in small numbers only in the cultures from 7.

They were on the average a little longer than the virulent bacilli from the cases of suspected diphtheria examined on the same days. In broth the bacilli from 13 of the 24 cases grew characteristically, while from 6 they caused a more or less dense cloudiness. It was found, however, that sometimes the virulent bacilli produced the same effect, though never to the same degree, as the bacilli from case 191. In 5 cases the bacilli were not grown in broth. In all the cases in which broth cultures were made (19) the bacilli produced acid in their growth. When their acid-producing power was compared with that of an equal number of virulent cultures no marked difference could be noted. Some virulent bacilli were found to produce more acid than the non-virulent ones, while others produced less.

Upon blood-serum the bacilli grew in a manner characteristic of the Loeffler bacillus.

Upon agar the bacilli from 11 cases grew as the virulent bacilli usually grow, while from 7 they grew in a less typical manner, but always in ways seen exceptionally in the virulent form. Guinea-pigs were inoculated with the bacilli from 15 cases. The lack of virulence in the bacilli from the remaining 9 cases was taken for granted from their close association with the 15 tested. Half-grown guinea-pigs were employed, and they were inoculated under the skin with from one-half to three-fourths per cent. of their weight of a forty-eight hour broth-culture. In only one animal was there any appreciable reaction, and in this the local induration caused passed away within four days. A very slight degree of immunity was given to some of the pigs by the injection.

The bacilli persisted in 4 of the throats for four weeks, in 1 for three weeks, in 3 for two weeks, and in some of the others for shorter periods.

Column three of the table shows that in 27 cases pseudo-diphtheria bacilli were found corresponding to those described by Hofmann and Escherich and photographed by Koplik.[19] Upon agar some of the bacilli grew in a similar manner to the diphtheria bacilli, while others grew as described in the table given opposite. The bacilli were smaller, shorter, thicker, and more uniform in size than the Loeffler bacilli and always formed alkali in their growth in broth. These bacilli were never virulent in animals.

Guinea-pigs were inoculated with large amounts—one-half to one per cent. of their weight—of broth cultures of bacilli obtained from 8 cases without showing any reaction.

As is shown in column one of the table, virulent diphtheria bacilli were found in 8 of the 330 cases.

They were in all probability derived from mild cases of unrecognized diphtheria, or from healthy children who were carrying the bacilli in their throats. The number of such infected children is indicated by the results of studies described in the following pages.

4. (*b*) *Are Virulent Diphtheria Bacilli ever Present in the Throats of Healthy Persons who have been brought in Contact with Diphtheria?*—The search for the origin of obscure cases of diphtheria has revealed the fact that it is possible for the human throat to become the habitat of the virulent Loeffler bacillus without any visible lesions resulting. Thus Loeffler[3] found the virulent bacillus once, Fraenkel[24] twice, and Escherich[18] found it in several cases. In one of Escherich's cases the history is so significant as to be worth repeating. It was noticed among the children coming under the care of a certain apparently healthy nurse a number of cases of diphtheria were developing. A bacteriological examination being made, her throat was found to contain very numerous virulent diphtheria bacilli. These remained present and virulent for weeks. A similar and interesting case is reported by Feer.[25] In a diphtheria epidemic occurring in a hospital ward, due to a single infection, the throats of seven children became infected. The infection caused fatal diphtheria in four, an acute angina without membrane in two, and no symptoms whatever in one. In all of these the bacilli were abundant and equally virulent. Many similar examples have been met with by us.

A very interesting investigation has been carried on to determine how frequently the throats of healthy children became infected in families where one is sick with diphtheria, and where little or no isolation is possible.

As will be seen by the following tables, the throats of the healthy children of fourteen families, in which one or more of the other members had diphtheria, were examined. There were in all forty-eight healthy children. In fifty per cent. of these diphtheria bacilli were found; forty per cent. developed later, to a greater or less extent, the lesions of diphtheria.

Family.	No. of Cases examined aside from the Original Case of Diphtheria.	L. Bacilli found in—	L. Bacilli not found in—	Remarks.
A.	1	0	1	Isolation partial.
B.	3	3	0	No isolation; all three cases subsequently developed diphtheria.
C.	2	1	1	No isolation
D.	1	1	0	No isolation
E.	3	1	2	No isolation.
F.	4	1	3	Isolation partial.
G.	5	3	2	Isolation partial.
H.	4	3	1	No isolation.
I.	4	1	3	Isolation partial.
J.	8	3	5	Isolation partial.
K.	4	1	3	Isolation partial.
L.	3	1	1	Isolation partial.
M.	5	3	2	Isolation partial.
N.	1	1	0	No isolation.
14	48	24	24	

Of the above cultures in which the Loeffler bacilli were found, in six the virulence was tested in the usual way. The results are stated in the following table:

Family No.	Case No.	Amount Bouillon-cult. inoc.	Guinea-pig. Weight.	Virulence.	Clinical History.
B.	1	1.33 c. c.	337 gm.	Died in 40 hrs.	Developed fatal diph. 1 day after cult. was taken.
G.	2	1	205 gm.	Died in 44 hrs.	Developed tonsillar diph. 2 days after cult. was taken.
H.	3	1.33	222 gm.	Died in 48 hrs.	No subsequent development of diphtheria.
K.	4	1.33	300 gm.	Died in 40 hrs.	No subsequent development of diphtheria.
M.	5	1.66	490 gm.	Died in 40 hrs.	No subsequent development of diphtheria.
N.	6	1	250 gm.	Died in 40 hrs.	No subsequent development of diphtheria.

In considering the high percentage of cases in which the virulent Loeffler bacillus was found, it must be remembered in these families the conditions were the best possible for the transmission of the contagium.

In numerous instances cultures have been made from the throats of healthy children in families where the diphtheria case was well isolated; in such cases the bacilli have been found in less than ten per cent. of the children.

It may be interesting to detail here two instances out of many observed in which the virulent bacilli of diphtheria derived from healthy throats have been the cause of diphtheria in others.

1. A child was admitted into a hospital ward in an anæmic condition and with a chronic coryza. Five days later four children in his neighborhood developed diphtheria. Two of these died. In seeking the cause of the diphtheria suspicion was directed to the child by a slight nasal discharge. Bacteriological examination showed this secretion contained many diphtheria bacilli. On further examination it was found the child came from a family in which three weeks before there had been a case of diphtheria.

2. In a family of eight children one child sickened with diphtheria; and a second child, a baby, was sent to a neighbor. The next day cultures showed this baby, as well as two of the other children, all of whom were apparently healthy, were infected with diphtheria bacilli. The three apparently healthy but infected children, as well as the sick one, were at once quarantined, but already one of the family to which the baby had been sent had contracted diphtheria from it.

The practical value of bacteriological examinations of the throats of healthy children in families where isolation has not been carried out in the first days is further shown by the fact that those children in whom the bacilli are found are extremely apt to develop diphtheria in the course of a few days, when no cleansing treatment is adopted, while they seem much less liable to do so if kept under treatment.

The detection of the virulent bacilli in throats prevents the dissemination of diphtheria by allowing us to isolate those infected. A very striking instance of this was the following: In a family of four children one was sick with diphtheria. The Department Inspector found three other children in the same bed with the sick one, who was constantly spitting upon and soiling the bedclothes. He made cultures from these three children, whose throats appeared healthy, as well as from the sick one; all contained abundant characteristic Loeffler bacilli. (These were later shown to be virulent by the inoculation of guinea-pigs.) When the Inspector visited the same family three days later, he found two of the previously healthy children had meanwhile sickened and died, and that the third was severely ill. This child finally recovered.

From the observations detailed above we cannot escape the conclusion that all members of an infected household should be regarded as under suspicion, and in those cases where isolation is not enforced, the healthy as well as the sick should be prevented from mingling with others until cultures from the throat have shown the absence of bacilli or a sufficient lapse of time gives the presumption that they are not carriers of the contagium.

Summary and Conclusions on Diphtheria Bacilli in Healthy Throats.—We have found that children, and to a less extent adults, who are brought in direct contact with true cases of diphtheria very often receive the diphtheria bacilli into their throats, and that these bacilli may persist and develop in these throats for days or weeks. In some cases we have found that true diphtheria followed the appearance of the bacilli in the respiratory passages, while in others no disease developed, though they might be the source of diphtheria in others. The examination of the throats of three hundred and thirty healthy persons in whom no contact with diphtheria was known, revealed the presence of virulent bacilli in but eight persons, two of whom later developed diphtheria.

We must conclude, then, that virulent diphtheria bacilli are to be found in the throats of a small proportion of healthy persons throughout the city, and that they have been derived either directly from diphtheria cases or from those who have been in contact with them. The examinations of the throats of the three hundred and thirty healthy persons showed that in twenty-four bacilli existed in every way identical with the Loeffler bacillus, except that they were not virulent in animals. As the bacilli in cases of true diphtheria are known to gradually lose their virulence, and as this loss of virulence can be caused artificially, it seems to the writers that these bacilli, characteristic except as to virulence, should be regarded as true diphtheria bacilli which have lost their virulence.

The examination of the same throats showed that, in twenty-seven there were bacilli present which were so uniform in their peculiarities as to staining, size, shape, and the production of an alkali instead of an acid, that there seems to us to be even more reason to separate them from the diphtheria bacillus than there is, for example, to separate the colon bacillus from that of typhoid.

TABLE I.—FALSE DIPHTHERIA.

Family Number.	Children in Family.	Case Number.	Age.	Severity.	Duration of Illness.	Mortality.	History of Contagion, etc.
1	1	1	4 years	Mild	7 days	Recov.	Came from a house where diphtheria was present.

50	6	57	7 years	"	3 days	"	"

We have never found bacilli possessing these peculiarities to be virulent, nor have they seemed to have any connection with diphtheria. It seems to us that to these bacilli alone the name pseudo-diphtheria bacillus should be given. The few bacilli which do not seem to come under either of these divisions must await further study before being classified.

5. *To what Degree is Pseudo-diphtheria Communicable?*—In the general circular issued by the Department, it was announced that cases which bacteriologically proved to be false diphtheria would not be kept under the supervision of the Department. Some who approve heartily of the rest of the work of the Board in its dealings with diphtheria believe in this step it has made a mistake, and that the pseudo-diphtheria cases, though less contagious than the true, are yet sufficiently so as to render isolation necessary. From the experience obtained in the diphtheria hospital, it was believed these cases were

so little, if at all, contagious, that visiting by the Department inspectors was unnecessary. Nevertheless, to investigate this question thoroughly, four hundred and fifty cases of false diphtheria, as nearly consecutive as possible, were investigated, all sources of contagion sought for, and the cases followed up for two weeks after complete convalescence. In none of these was isolation or disinfection enforced by the Health Department.

TABLE III.—TRUE DIPHTHERIA CASES FROM THE SAME DISTRICT AS THE FALSE DIPHTHERIA IN TABLE I.

Family Number.	Children in Family.	Case Number.	Age.	Severity.	Isolation.	Mortality	History of Contagion, etc.
1	5	1	4 years	Moderate	Poor	Recov.	None.
2	4	2	11 years	"	"	"	Previous case four weeks before.
3	1	3	3 years	Severe	Good	Died	None.
4	4	4	2 years	Slight	None	Recov.	"
5	1	5	10 years	"	Good	"	Other cases in school.
6	2	6	3 years	Moderate	None	"	Two days before two children in same family died of "diphtheria." At time of culture child was not sick, but developed diphtheria later.
7	1	7	5 years	"	Good	"	None.
8	4	8	5 years	"	None	"	"
9	2	9	6 years	Slight	Poor	"	Two children had just died of diphtheria in family.
10	1	10	2 years	Severe	Good	Died	None.
11	4	11	3 years	Slight	None	Recov.	From Case 3, which was in adjacent room.
12	4	12	10 years	"	Good	"	None.
13	1	13	8 years	Severe	"	"	"
14	2	14	7 years	Slight	"	"	Sent away for safety from family in which there was a case of diphtheria.
15	2	15	4½ years	Severe	"	"	Fatal case previously in family.
16	1	16	1½ year	"	"	"	Servant had just come from Case 9, where there had been three cases in family.
17	1	17	2 years	Moderate	"	"	None.
18	4	18	5 years	"	Poor	"	Case of diphtheria on floor below.
19	3	19	9 years	"	Good	"	Two fatal cases just previous to this case.
20	3	20	3 years	Severe	"	"	Other cases in school.
21	1	21	4 years	"	"	Died	None.
22	5	22	6 years	Slight	Poor	Recov.	From a candy store. The proprietor's child had diphtheria. This store seemed the cause of several cases in street, and in a school.
23	3	23	5 years	Severe	"	"	Previous case in house.
		24	3 years	"	"	Died

SUMMARY OF TABULATED CASES.

	Table I. (50 Families) Pseudo-diphtheria.	Table II (50 Families (Pseudo diphtheria.	Table III. (50 Families) True Diphtheria.
Total number cases	56	57	60
History of contact with other cases	7	7	33
No history of contact	49	50	27
Families in which more than one case developed	5	4[1]	13
Recovered	56	53	46
Died	0	4[2]	17
Cases complicated by scarlet fever	4	6[3]	

[1] Two had scarlet fever.
[2] Three of which had scarlet fever.
[3] Six others had been in contact with scarlet fever, but never showed any characteristic rash.

This is such an important question that the results of the investigation of one hundred consecutive cases are given here in tabular form. As a comparison, a similar table is given of fifty consecutive cases of true diphtheria which were taken from the same district and at the same time of the year as the first fifty cases of pseudo-diphtheria.

We find, therefore, in 113 cases of false or pseudo-diphtheria, occurring in 100 families, that 14 occurred at the same time with, or shortly after, some other case, and that it is possible to assume the disease had been directly communicated to them. In 9 of the 100 families more than one case developed. In these, as in the other 350 cases of pseudo-diphtheria investigated, it did not seem secondary cases were any less liable to occur where the primary case was isolated, than when it was not. In this connection we must remember mild throat inflammations are very frequent, especially in the early spring months, and that it is quite possible where two cases occurred in a family together, or within a short period of each other, that they may have both been due to exposure to some common condition rather than to direct transmission. The presence in nearly all healthy throats in New York City of streptococci renders this assumption almost a probability. The presence of the same germs in healthy throats as in those of patients suffering from pseudo-diphtheria prevents us from deciding the point by bacteriological examinations. A good illustration of the difficulty in determining whether these cases are communicable is the following:

In a family of eight there were, a mother, aged forty-five, six children whose ages ranged from twenty-five to ten, and a grandchild aged two. The family lived on the top floor of a tenement. Two days before being visited by the Inspector of Diphtheria a heavy, wet snow had fallen, which, as the roof leaked, caused the walls to become very damp. The next morning four of the children were attacked by more or less severe tonsillitis, which later developed follicular deposits or croupous patches. On the following day the baby had an attack of croup. All recovered and no further cases developed in the tenement. Here the exposure to dampness certainly seems to be the explanation of the first four cases of tonsillitis, but the occurrence of laryngitis in the baby might with equal justice be considered as due to the dampness, or as the result of communication from the others.

Even if further investigation should seem to prove the 14 cases of pseudo-diphtheria out of 113 tabulated which were found to have had some connection with other mild sore throats, were due to contagion and not to the simultaneous effects of atmospheric or other deleterious conditions, there would still be an important practical objection to sanitary supervision or enforced isolation. All of the 14 cases, except 3 who had scarlet fever, were mild, and, indeed, leaving out of consideration the cases which occurred as complications of scarlet fever, there was only 1 death in 103 cases of pseudo-diphtheria, and in this case, as has been said, there was no history of infection or contact with other cases.

6. *What are the Means by which Diphtheria is Trans-*

mitted?—The facts brought out by the investigations of the Department throw important light on the manner in which diphtheria is transmitted.

As related to this question let us first consider very briefly what is known of the duration of life of the Loeffler bacillus outside of the body.

In actual experiments the Loeffler bacillus has been found to live for long periods of time, namely: by Hofmann, on blood serum, for one hundred and fifty-five days; by Loeffler and by one of us (Park) for seven months; and in gelatine by Klein, for eighteen months. The bacilli have been found to live in bits of dried membrane by Loeffler for fourteen weeks, by us for seventeen, and by Roux and Yersin for twenty weeks. Dried on silk threads, Abel [26] reports they may sometimes live for one hundred and seventy two days, and upon a child's plaything, which had been kept in a dark place, they lived for five months.

As examples of the manner in which diphtheria may be contracted, he gives the following from Johannessen: [27]

A teacher developed diphtheria from passing the night in a room in which three weeks before a fatal case had occurred.

A child developed diphtheria after putting on the clothing worn by a child which had died of diphtheria two months before.

In a number of isolated dwellings diphtheria developed nearly a year after previous outbreaks, without there being any apparent possibility of a new infection taking place from outside.

We ourselves have met with a number of cases where the infected bedding or clothing has undoubtedly been the source of the infection.

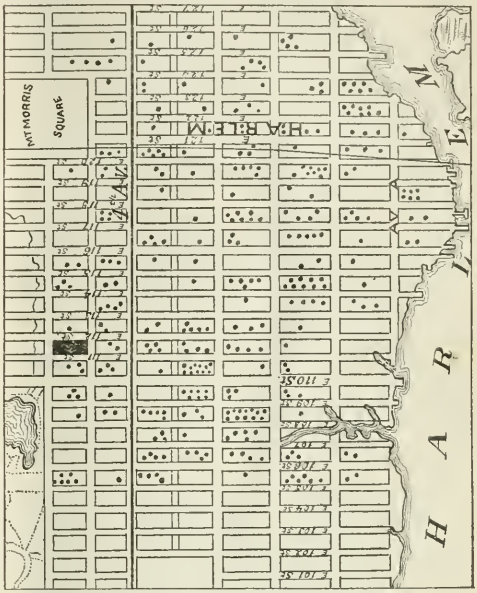
Sources from which Virulent Bacilli may be Received.—1. From the pseudo membranes, exudate, or discharges from diphtheria patients. 2. From the secretions of the nose and throat of convalescent cases of diphtheria in which the virulent bacilli persist. 3. From the throats of healthy individuals who have acquired the bacilli from being in contact with others having virulent germs on their person or clothing. In such cases the bacilli may sometimes live and develop for days or weeks in the throat without causing any lesion.

When we consider it is only the severe types of diphtheria that remain isolated during their actual illness the wonder is, not that so many, but that so few persons contract the disease. This seems to be more remarkable when we observe that, in a city like New York, the whole tenement-house district at least is an infected area. This has become evident from the observations made by the Department.

It has been the practice of the Department during the last year to plat upon a city map the location and date of every case of diphtheria in which the diagnosis had been settled by bacteriological examination. After several months the map presented a very striking appearance. Wherever the densely crowded tenements were located, there the marks were very numerous, while in the districts occupied by private residences very few cases were indicated as having occurred. It was also apparent the cases were far less abundant, as a rule, where the tenements were in small groups, than in the regions of the city where they covered large sections. At the end of six months there were square miles in which nearly every block occupied by tenement-houses contained marks indicating the occurrence of one or more cases of diphtheria; and in some blocks many cases (fifteen to twenty-five) had occurred.

As the platting went on from time to time the map showed the infection of a new area of the city, and often the subsequent appearance of a local epidemic. It was interesting to note two varieties of these local epidemics; in one the subsequent cases evidently were from neighborhood infection, while in the second variety the infection was as evidently derived from schools, since a whole school district would suddenly become the seat of scattered cases. At times in a certain area of the city, from which several schools drew their scholars, all the cases of diphtheria would occur (as investigation showed) in families whose children attended one school, the children of the other schools being for the time exempt.

Another fact noted—perhaps as important as the foregoing—was that with the most careful inquiry it was impossible to find, in about one-half of the cases of diphtheria which first occurred in a house, any connection with preceding cases of diphtheria.



An Average Section of the City in which each Dot indicates where a Case of Diphtheria Occurred during a Period of Six Months.

The two following histories are instructive as showing that special conditions, which are largely unknown to us, determine in every individual the occurrence or escape from diphtheria under exposure. Two children in a family were taken sick with diphtheria and removed to the hospital. The servant who was, and remained apparently, healthy went to another family, where the youngest child developed diphtheria a week later. In the meantime a case developed in the family living in the next apartment. There were in this latter family three other children which were not isolated at all from the sick child, yet none of these developed diphtheria.

The child of a man who kept a candy store developed diphtheria; there were four other children in the family and these were in no way isolated from the sick, yet none of them developed diphtheria, but children who bought candy at the store, and other children coming in contact with these in school developed diphtheria. The secondary cases ceased to develop so soon as the candy store had been closed.

Many similar histories could be given to illustrate the fact that the majority of persons, and even perhaps the majority of children, are not ordinarily very susceptible to diphtheria, and that in addition to receiving the germs of the disease into the respiratory passages they must be in a condition favorable to the development of the disease, and their mucous membranes must be vulnerable.

It seems to be generally true that the more malignant a case of diphtheria is, the more likely it is to cause diphtheria in others. This may be due to the high grade of virulence possessed by the bacilli or to the peculiar association of other micro-organisms in the membrane, or to

the wider dissemination of the infectious matter through the discharges.

It is also well known that young children are much more susceptible to diphtheria than older persons. It is comparatively rare for the parents of children sick with diphtheria to contract the disease, although in nearly every case they must at some time receive the germs into their throats.

Conclusions.—1. All inflammations of the mucous membranes due to the diphtheria bacillus of Loeffler should be included under the name diphtheria, and in this report they have been so included. An acute hyperæmia of the mucous membrane, caused by the Loeffler bacilli, is considered as truly diphtheria as an inflammation with pseudo-membrane or exudate, and a case in which the lesions are confined to the larynx or bronchi as truly diphtheria as one in which the tonsils and pharynx are involved.

2. Under pseudo diphtheria should be included all inflammations of the mucous membranes which simulate true diphtheria and which are due to streptococci, or, more rarely, other cocci.

3. The name croup, or membranous croup, should be regarded as a term merely indicating that the location of the pseudo-membranous or exudative lesion is in the larynx, and not as describing the nature of the disease, whether diphtheritic or pseudo-diphtheritic. In New York City at the present time eighty per cent. of the cases of "croup" are diphtheria.

4. The examination of cultures made upon solidified blood-serum under the conditions insisted on by the Department form a reliable method for determining whether the diphtheria bacillus is present or absent in a throat. For diagnostic purposes cultures should be made before the pseudo membranes or exudate begins to disappear.

5. Virulent diphtheria bacilli were apparently present in about one per cent. of the healthy throats in New York City at the time of these examinations. Diphtheria was, however, rather prevalent at this time. Most of the persons in whose throats they existed had been in direct contact with cases of diphtheria. Very many of those whose throats contained the virulent bacilli never develop diphtheria. We must therefore conclude that the members of a household in which a case of diphtheria exists should be regarded as sources of danger, unless cultures from their throats show the absence of virulent diphtheria bacilli.

6. The bacilli found in the original serum cultures, which in appearance and staining are identical with the typical Loeffler diphtheria bacillus, may be regarded, for diagnostic purposes, as virulent diphtheria bacilli, if the cultures have been made either from throats containing exudate, or from those of persons who have been in contact with true diphtheria, for investigation has shown that over ninety-five per cent. of such bacilli are virulent. Bacilli, on the other hand, which resemble the pseudo-diphtheria type must be subjected to both cultural and animal experiments before their nature or virulence can be judged.

7. All bacilli which are identical with the virulent Loeffler diphtheria bacillus, morphologically, biologically, and in staining by reagents, should be classed with the diphtheria bacilli, whether they have much, little, or no virulence when tested on guinea-pigs. Bacilli which have entirely lost their virulence rarely, if ever, regain it. They probably are incapable of causing diphtheria, for the twenty-four cases in which they were found by us never developed any lesions, nor were they the original of any case of diphtheria, so far as could be ascertained.

8. The name pseudo-diphtheria bacillus should be regarded as applying to those bacilli found in the throat which, though resembling the diphtheria bacilli in many respects, yet differ constantly in others equally important. These bacilli are rather short, and are more uniform in size and shape than the typical Loeffler bacillus. They stain equally throughout with the alkaline methyl-blue solution, and produce alkali in their growths in bouillon. They are found in about one per cent. of the healthy throats in New York City, and seem to have no connection with diphtheria. They are never virulent.

9. One or more varieties both of streptococci and of other forms of cocci exist in the great majority, and possibly in all, of the healthy throats in New York City. Cultures from the throat in cases of pseudo-diphtheria contain more cocci, especially more streptococci, than those from healthy throats, but otherwise do not seem to differ.

10. The investigations of the Health Department have given striking evidence of the marked difference in mortality between true and pseudo diphtheria, for while it was twenty-seven per cent. in diphtheria, it was under two per cent. in pseudo diphtheria.

11. The combined clinical and bacteriological investigation of over five thousand cases has demonstrated clearly the fact that many of the less characteristic cases of diphtheria and pseudo diphtheria are so similar in appearance, symptoms, and duration, that it is impossible to separate them, except by bacteriological examinations. In the more severe cases, and after the disease has fully developed, cultures are less necessary, although their systematic use is desirable.

12. Persons who have suffered from diphtheria should be kept isolated until cultures prove the bacilli have disappeared from the throat, for not only are the bacilli which persist in the throat virulent, but they are not infrequently the cause of diphtheria in others. Where cultures cannot be made, isolation should be continued for at least three weeks after the disappearance of the membranes, for our experience has shown that it is not unusual for the bacilli to persist that length of time.

13. In pharyngeal cases in which thorough irrigation of the nostrils and throat with 1 to 4,000 bichloride of mercury solution has been practised every few hours, the bacilli have not remained in the throat for as long a time after the complete disappearance of the pseudo-membrane as when no antiseptic has been employed. Other antiseptic and cleansing solutions may be also useful.

14. Inflammation of the mucous membranes due to streptococci, either alone or associated with other cocci, are usually mild in character. These inflammations may be more serious when the lesion is located in the larynx, or when they are complicated by scarlet fever or measles.

15. While the streptococci, and perhaps other forms of cocci, may be considered as the primary etiological factor in pseudo-diphtheria, yet, in the majority of cases at least, certain predisposing factors, such as exposure to cold or other deleterious influences, or the presence of certain infectious diseases, appear to be of great importance in determining the occurrence of the disease.

The streptococci which under these conditions apparently cause the disease are probably those which had for a long time existed in the throat, and not those freshly derived through communication with other cases of pseudo-diphtheria. In a small number of cases, indeed, the histories suggest a direct communication, but the causation may be equally well explained by the supposition that the second case shared with the original one the same predisposing cause.

16. The slight mortality and the usual mildness of the cases of pseudo-diphtheria do not warrant us in enforcing isolation, even if further investigation produce positive proof that this disease is directly communicable.

With the results of these investigations before us we can appreciate the difficulty of exterminating diphtheria from a city like New York. On the one hand, we have cases of diphtheria scattered all through the city, many of which are so mild as to be unrecognized, and on the other hand, we have the crowded tenements with their ignorant and shifting population, where proper isolation of the patient from other members of the family, or of the family from other inmates of the building, is usually impossible unless harsher measures are adopted than

are now customary. With stricter isolation of patients, and intelligent and systematic supervision of the schools and tenements, we can certainly reduce the number of cases of diphtheria in the city, but the total extermination of the disease, under the existing conditions of life here, does not seem probable unless one can acquire new means to combat the disease.

THE AFFINITY OF GOUT AND RHEUMATISM.

BY R. SHAWE TYRRELL, M.D., L.R.C.P. LOND.,

TORONTO, CANADA.

THE time, no doubt, is rapidly drawing to a close when retention of excess of excrementitious matter will any longer be tolerated during the treatment of diseases in general.

Not a score of years ago the practice in London was, as everybody knows, to lock up the bowels for a fortnight or more during the course of enteric fever, and this mode of treatment was instituted by the very man, viz., Murchison, who enlightened the medical world on the subject of lithæmia, and as his custom in typhoid fever has long since been abandoned, so also has his theory regarding the production of lithæmia been brought into question. The object, however, of this paper is to endeavor to show the close relation which exists between gout and rheumatism. And if the cause of gout is, and has been for some time quite apparent and beyond dispute, viz., uric acid in excess in the system; and if, on the other hand, the cause of rheumatism is still in doubt, may it not be justifiable to draw attention to this close resemblance between these diseases, and, if possible, to explain why their effects are somewhat different.

I well remember the late Dr. Murchison diagnosing a case of severe inflammatory affection of the elbow joint, which was not preceded by a local injury, as a first attack of gout, and his opinion was corroborated by subsequent events. This case, I need hardly say, occurring on one of the larger joints as a primary attack, would probably suggest the conviction to many minds of so-called rheumatic origin. And Garrod says, "It is not uncommon to hear a patient call the disease gout as long as it is confined to the feet, but rheumatism or rheumatic gout when the upper extremities become attacked, although the same condition of the system which causes the one gives rise to the other." One naturally infers that the patient referred to above calls his disease what his physician does, and that a certain amount of doubt is in many cases manifest in regard to its etiology, particularly if the disease be of a chronic character or situated in the muscles; many aches and pains and neuralgias which were formerly designated rheumatic are now held to be lithæmic, and give way under an eliminative mode of treatment. It is, I say, in the chronic forms of rheumatism and gout that one notices the resemblance is the most marked. I think that lumbago, which is considered a form of muscular rheumatism, is always lithæmic in origin, and certainly purgation and diaphoresis have, in my hands, given more satisfactory results than the accepted mode of treatment by acupuncture. Osler says, "persons of a rheumatic or gouty habit are certainly more prone to this affection." Here again we have an uncertainty expressed.

Dr. Beverley Robinson, of New York, has stated that in his hay-fever patients he has frequently noticed a rheumatic habit, while Dr. Bishop, of Chicago, and I have independently proved, at least to our own satisfaction, that the affection is lithæmic in origin. There is, no doubt, in that pronounced form of gout occasioned by an excess of alcohol some characteristic appearances which frequently stamp it as a distinct affection from acute rheumatism, caused, I will state, by a loaded condition of the system due to inactive organs, plus some exciting cause; but in many cases the physician is severely taxed before he arrives at any definite conclusions, possibly because there has been noticed not only an alcoholic habit, but also defective elimination; with exposure. In the one case the attack has been occasioned solely by the effects of an excess of alcohol or its products circulating through the blood. In the other case the supply of alcohol or food may not have been in excess, but due to faulty elimination—the effete products circulate through the blood and give rise to the inflammatory condition known as rheumatism. The hypothesis which I rely upon is, that both gout and rheumatism are due to inefficient elimination; if in the one case the kidneys, bowels, and skin could be made to do excessive duty we would have no gout, and if this same activity could be constantly kept up we would have no rheumatism. If this be tenable I think we are approaching the cause of rheumatism, and may possibly class it with gout under the term "Lithæmia." Now in regard to the results of these affections Garrod says that in all cases of gout you have a diseased condition of the kidneys, and it is well known that one finds a small amount of uric acid and urates in the urine in cases of gout due to this diseased condition, and consequently one naturally expects that this uric acid and urates will make their appearance somewhere, which always occurs frequently, but not always, in the joints; but in the case of rheumatism the kidneys are not diseased, and hence you do not have a deficiency of uric acid and urates in the urine, but an excess, and consequently you would not look for uric acid in the blood or deposits of urates or biurates in the joints or elsewhere, because the kidneys being active and healthy are able in time to carry them off, so that this distinction between gout and rheumatism, in regard to uric acid in the blood, and biurates of soda in the joints, is explained by the condition of the kidneys. I have had many cases of so-called rheumatism which have in after-years developed the usual symptoms of gout, and I explain the fact in this way, that at first the kidneys were active and healthy and afterward became diseased.

Again, youth is the special time for rheumatism, when the kidneys are liable to be healthy. Middle age is the choice time for gout, when these organs are more prone to disease. And in this connection I may say that experience has taught me that there is a transitional stage between healthy and diseased kidneys when chemical and microscopical examinations of the urine is of small practical value.

I have stated that rheumatism is caused by a loaded condition of the system (by this I mean an excess of uric acid and urates), plus an exciting cause, viz., cold and dampness; this exciting cause occasions an explosion, as it were, in this way. That it not only shuts off

all excretion by the skin, but also causes a congested condition of the internal organs which interferes with their eliminative action, particularly that of the liver, and hence you have the system suddenly charged with waste products, so that cold is essentially the exciting cause in producing this congested condition which prevents elimination as is evidenced from the fact that in tropical climates we find no rheumatism. Do you not always find a state of constipation in acute rheumatism, and is not purgation combined with diaphoresis the most satisfactory mode of dealing with this disease? as it is also, in my experience, the most efficient way of cutting short an attack of gout, and it is hardly necessary to say that the large class of dyspeptics which we come across daily are relieved most effectually by purgation; in fact, elimination by the bowels and skin probably relieves more suffering and avoids more acute attacks of illness than all other forms of treatment combined. I have been in the habit for several years of advocating the theory that in order to enjoy good health it is, as a rule, not only necessary that the bowels should be moved daily, but that they should be freely moved daily, and I think that if this principle were urged to a greater extent than it is we would have much less rheumatism and gout, or, as I will take the liberty of saying, a marked diminution in cases of lithæmia in general.

KLEBS-LOEFFLER BACILLUS IN HEALTHY THROATS AND IN MEASLES THROATS.

By ROBERT S. ADAMS, M.D.,

RESIDENT PHYSICIAN NEW YORK FOUNDLING HOSPITAL, NEW YORK.

As the present belief in this city is that the Klebs-Loeffler bacillus in nose or throat is diagnostic of true diphtheria, and its absence characterizes false diphtheria, and that until the bacilli are absent from the nose or throat, no matter how long after the disappearance of a pseudo-membrane, the case is to be considered as one of true diphtheria, the following account of a series of investigations made at the New York Foundling Hospital, in March of this year, Dr. J. J. Reid attending, may prove of interest:

Seventy-nine cultures in all were made. All cultures were sent to the Board of Health and examined by the inspector of diphtheria, Dr. Park. Of these 79 cultures 51 were made from throats that appeared, clinically speaking, perfectly healthy, while 28 were made from throats of children during or shortly after the eruption of measles. Of the 51 clinically healthy throats 10 were in perfect health and in a nursery entirely free from disease, and 12 were convalescent or surgical cases in hospital, but able to be about, and enjoying in general excellent health. Nineteen were made from throats of children coming to the Out-door Department. In these 51 healthy throats the Klebs-Loeffler bacillus was found in 7 cases, while 1 had suspicious bacilli which in subsequent cultures seemed to be pseudo-diphtheritic bacilli. Only one of these cases has since developed any clinical symptoms of diphtheria, viz., laryngeal diphtheria and stenosis requiring intubation. He recovered, but died of pneumonia one month after stenosis had disappeared.

In the 28 measles throats Klebs-Loeffler bacilli were found in 9 cases, pseudo-diphtheritic bacilli in 3 cases, and suspicious bacilli in 2 more, one of which proved to be genuine Klebs-Loeffler. Of these 10 cases of Klebs-Loeffler bacilli in measles throats none showed any clinical manifestations of diphtheria, while the one showing at first suspicious bacilli, and afterward true Klebs Loeffler, died of broncho-pneumonia, but showed no membrane in air-passages post mortem. The pneumonia was the typical catarrhal pneumonia of measles. Almost all the cultures were made from children of three to four years of age, and were made with the greatest care. In many cases extra cultures were made subsequently for greater certainty. To take up the cases somewhat more in detail: Cases I. to X. were made on one floor of the hospital proper from convalescent children who were allowed to eat at the same little table in an adjoining room and play together. When the reports of Klebs-Loeffler in two of the cases were received, they were promptly isolated and treated.

Case I. (Culture No. 3).—Eugene W——, aged three, suffering from anæmia, well nourished, no cough, called "doll baby" from his perfect face and pettish actions. Soft blowing murmur, generally heard best over pulmonary interspace, which disappeared entirely under treatment until at the time culture was made it could no longer be heard and child seemed perfectly well. Three days after culture was made laryngeal diphtheria developed, and intubation became necessary; tube removed on fifth day, reinserted on sixth day, and finally removed four days later; patient gradually improved, but remained in weakly condition and died of broncho-pneumonia a month after first intubation. Culture of this case proved virulent in guinea pigs.

Case II. (Culture No. 1).—Denny C——, aged four, convalescent from croupous pneumonia for two weeks and playing around with the other children. Throat appeared perfectly normal, culture contained many typical Klebs-Loeffler bacilli, which proved virulent in guinea pigs. No membrane or further manifestations of diphtheria appeared, and a little treatment soon removed bacilli. Has been perfectly well since. An interesting point in connection with these two histories is that three days later No. 4 developed typical diphtheritic patches on both tonsils, and cultures showed abundant Klebs-Loeffler. She recovered nicely under treatment, and culture about a week later showed no Klebs Loeffler, none having been found in her original culture.

Culture No. 2.—Maggie W——, a child suffering from marked rachitis showed two well-marked patches of pseudo-membrane a few days after original cultures; some temperature, enlarged glands, prostration, etc., but no Klebs Loeffler were found in original or two later cultures. Hers was an obstinate case, but she recovered after vigorous treatment. Now here were ten children not having been exposed to diphtheria, in good general condition, with apparently perfectly healthy throats, no enlarged tonsils, nor adenoids, nor nasal catarrh, one of whom developed laryngeal diphtheria, apparently giving diphtheria to another, and infecting one with true and another with false diphtheria.

Culture No. 7, who had suspicious bacilli at first culture, showed pseudo-diphtheritic bacilli, but no further manifestations of diphtheria, and the bacilli disappeared with treatment.

The following cases were in other wards:

Case III.—Stephen ——, aged five, tubercular osteo-arthritis ankle, showed Klebs-Loeffler typical, but no further sign of diphtheria, and treatment begun shortly after isolation. Showed no further bacilli.

Case IV.—Thomas C——, granular conjunctivitis, showed typical Klebs-Loeffler. No further manifestations of diphtheria.

Case V.—Annie W——, talipes equino varus, with special shoe fitted. Klebs-Loeffler found, but no subsequent diphtheria.

The two cases from the Out-patient Department showed true Klebs-Loeffler, but treatment removed bacilli, and no further symptoms appeared.

Of the 28 measles cases, in which cultures were made in all but 6 at time of eruption, typical Klebs-Loeffler were found in 10 cases. Four of these had croupy coughs, but only one of them had Klebs-Loeffler, while one had pseudo-diphtheritic bacilli. None showed any further trouble with the throats, the peculiar cough doubtless being due to a greater degree of catarrhal inflammation of the larynx. Two of these cases died of pneumonia, but no membrane was found post mortem.

From these cases, to sum up, we note:

1. Of 51 healthy throats, Klebs-Loeffler bacilli in 7; that is, 28 healthy throats in hospital, 5 Klebs-Loeffler;

19 healthy throats in Out-patient Department, 2 Klebs-Loeffler. Nearly one in seven is the proportion of Klebs-Loeffler in healthy throats.

2. Probable infection of a case from the Klebs-Loeffler bacilli in a throat in which at time of culture they were doing apparently no harm.

3. Occurrence of severe pseudo-diphtheria in a throat which contained no Klebs-Loeffler.

4. Cases of pseudo-diphtheritic bacilli in healthy throats.

5. The occurrence of Klebs-Loeffler bacilli in 10 out of 28 cases of measles throats, or in about one-third of cases examined, but apparently not adding clinical manifestations of diphtheria at a time when they should have found it easiest, *i.e.*, in inflamed measles throats. The bacilli were removed with much greater difficulty from half of the measles throats, they apparently finding the inflamed mucous membrane a good habitat. As all of these cases were promptly isolated and treated as soon as bacilli were found, no idea of the virulence of the bacilli can be obtained other than the few cultures inoculated in animals. All of these children have been under observation for the past three months, and none of them, save the single case requiring intubation, have since showed any sequelæ or further manifestation of diphtheria.

THE CERVICAL GANGLION OF THE UTERUS.

By BYRON ROBINSON, M.D.,

CHICAGO, ILL.

It would astonish any student to know how little has been published in regard to the nervous system of the female genitals which is of an original character. The reason for this is at once apparent when one pursues the study for several years. Of course, the simplest and easiest way is to dissect the genitals of man and animals. But few do that. And besides, to dissect with value and discrimination requires time, experience, and patience. The best way is to secure an infant cadaver and drop it in alcohol for several weeks, and for comparison secure some six to eight weeks' fœtal pigs from the slaughter-house and treat them likewise.

To get at the parts most readily, open the infant's abdomen and take away the hip-bone. Unjoint it at the sacro-iliac joint, then cut it away at the tip of the ischial spine, and then saw through the pubic rami at the centre of the obturator foramen. The field is now clear. Next, observe the course of the hypogastric plexus just beneath the peritoneum at the promontory of the sacrum. It will show itself like white threads shining through the peritoneum. The white lines are the hypogastric plexus and should be carefully followed by a sharp-pointed scissors as far as the region of the cervix. Now, with gentle care, clear away the various tissues from the roots of the first, second, third, and fourth sacral nerves. It will, by this time, be clear to the sight that the lower end of the hypogastric plexus and the branches from the sacral nerves (especially the third and fourth) converge near the cervix into a mass of white tissue. This mass of whitish-gray tissue is the ganglion of the cervix uteri. So far as I can ascertain, this ganglion was first described by a physician named Walter. The existence of the ganglion has been denied by Snowbeck, of the English, and by Kilian, of the French. The defenders of the ganglion are chiefly Lee (1842) and Frankenhausen (1867). The names of those who have worked at this ganglion are very few even to this day. The only worker on this ganglion that I know of in the last generation is Dr. Jastrobef, of St. Petersburg, in the clinic of Professor Slavjansky. Dr. Jastrobef used thirty bodies to secure anatomical and pathological knowledge. I have been working at the nervous system of the female genitals for some five years, and I did not become aware of Dr. Jastrobef's labors until August, 1894. Nearly every worker in this subject comes to essentially the same conclusions, but some little manifestations arise which induce said observer to think every other investigator overlooked. Lee and Frankenhauser showed with anatomical positiveness the largeness and solidity of the cervical ganglion; while Snowbeck and Kilian tried to belittle its size, and even its existence. Jastrobet's short account simply sides with the idea that the cervical ganglion is a mere plexus of nerves.

After careful dissecting (man and animals) I must say that the cervical ganglion is a veritable ganglion, just as the superior cervical ganglion is. The cervical ganglion is a real ganglion. It is true it varies in shape and size, as all sympathetic ganglia do. But it is constant and real. I shall carry on this investigation for the next few years in man and animals and prove its constancy. The last cadaver which I dissected for the purpose of identifying the ganglia for study was that of a woman about seventy years old. The ganglion was fully three-fourths of an inch long, and over one-fourth of an inch wide. It was a thick, hard, irregularly shaped mass of nerve-tissue receiving the hypogastric plexuses and the branches of the sacral nerves, and sending out many small nerves to the uterus, bladder, and rectum. The ganglion in this special case received all the branches of the sacral nerves before they entered the uterus, and all the nerves of the hypogastric plexus, except two or three, before they were sent to the uterus. It appears, then, that the cervical ganglion is the distributor of nerves to the uterus. It is no doubt the ganglion of the uterus. Its business is to control the uterus. Leashes of nerves start out of this ganglia to the uterus, bladder, and vagina. The vagina was, next to the uterus, the favored organ for numerous strands. The ganglia lie near the cervix, one on each side. In the above case the right cervical ganglion was much more solid and compact than the left. More than a dozen branches could be counted going to the uterus, to the vagina, and to the rectum, in the order of abundance. In this case of a woman seventy years of age the ganglion was perfect and distinct, as it is in an infant cadaver. The wonderfully intimate nervous connection of the uterus to both rectum and bladder should be a lesson to the gynecologist. The uterus, rectum, and bladder are richly supplied by many strands from the same great trunk (hypogastric plexus). It is almost impossible to irritate one organ without the other two being brought directly into the disturbed field.

During the last five years I have had many subjects (man and animals) to study the sympathetic nervous system, and one fact has, time and time again, impressed me. This fact is the widespread and profoundly intimate nervous connection of the kidney and genitals. So far as the nerve connection is concerned the organs should be written genito-urinary, with a distinct hyphen. The explanation arises in embryology, where both genital and urinary organs arise from the same source—the Wolfian body. I wish to give credit for this same idea to Dr. Frankenhauser, whose work I was able to secure only a few months ago, as it is out of print. A glance at a well-dissected sympathetic nervous system lying *in situ* would enable a physician to cast aside forever an error long propagated in obstetrics, and to my own knowledge taught even to this day from obstetric chairs. It concerns pressure over the sacral promontory to stop post-partum hemorrhage. It is taught that pressure compresses the aorta so that the blood is checked from going to the uterus. A few actual trials in obstructing the aorta by pressure will soon dispel the delusion. The facts in the case are that the irritation of the hypogastric plexus (in attempting to compress the aorta) induces the uterus to contract. The more pressure and vigorous irritation applied to the sacral promontory the more vigorous and certain will be the uterine contractions, so that the explanation of how post-partum hemorrhage is checked by compressing the aorta is certainly wrong. The mechanism is accomplished by the irritation of the hypogastric plexus. So far I have not had the opportunity of dissecting a pregnant uterus, to determine whether the cervical ganglia enlarge, but both Lee and Frankenhauser say

they do. It is probable, however, that John Hunter is correct in his suggestion that it is the connective tissue, and not the nerves themselves, which enlarges in pregnancy. Almost every investigator of the uterine nerves has come to the opinion that it is the infant cadaver which serves the best purpose. The nervous system of the infant is disproportionately large and is plain to the eye, and it can easily be separated from the delicate connective tissue. The cervical ganglia are very plain in the infant. Two to four nerve-branches pass along with the ovarian vein and artery to the ovaries. At the junction of the tube and uterus (*i.e.*, at the origin of the round ligament) the ovarian and uterine nerves join—anastomose. The cervical ganglion, of course, shrink after the menopause, but its shrinkage must be limited, as many of its branches supply the rectum and bladder, organs which persist in further use. Yet it appears to me that the rectum and bladder in old female cadavers are considerably atrophied as well as the uterus.

Jastrobef in his short article notes that in disease of the genitals on one side the ganglion of the same side is affected. He reports two cases where the ganglion and the genitals of the same side were both diseased. As a considerable portion of the cervical ganglia rests on the vagina, even total extirpation of the uterus would include but a very small part of the ganglia, for the cervical ganglia are situated too low down to be included in the extirpated uterus. These few remarks may call attention to the cervical ganglion of the uterus, its limited literature, the varied opinions as to its existence, shape, and size, as well as the slight records of its functions and pathology.

Progress of Medical Science.

The Significance of the Venous Pulse.—Dr. James Mackenzie divides the venous pulse into two forms, the auricular and the ventricular. The former, he says, presents distinct evidence of the functional activity of the right auricle. In this form there is also a wave due to the ventricle, and as it increases the auricular wave decreases and finally disappears, and thus the ventricular venous pulse is developed. The latter form is a more advanced stage than the auricular, and, as during its development there is a gradual fading of the auricular wave, there is a period when such terms do not sufficiently denote the character of the pulse; but the terms are convenient for descriptive purposes. The ventricular venous pulse appears only when there is organic disease of the heart itself (most commonly in valvular disease). When failure of the heart is functional and not due to organic disease of the valves, the auricular pulse persists to the end. Similar types of pulse may be recognized in the liver. Here the pulse appears only when there is organic disease of the heart. In many respects, says Dr. Mackenzie, more information regarding the various cavities of the heart can be obtained from the study of the venous pulse than from that of the arterial pulse. Thus, during a cardiac revolution the arterial pulse is in free communication with but one chamber, the left ventricle, only a portion of the time, whereas in the venous pulse the effects of the right auricle during its systole and its diastole may be observed, while the time of the appearance of the ventricular wave gives information regarding the degree of incompetence of the tricuspid orifice. Information may be gathered regarding the exact time of closure of the pulmonary valves, and the persistence of the ventricle in systole for a short time after the outflow through the arterial orifices has ceased may be noted. There is also distinct evidence of the diastole of the right ventricle in the venous pulse. In heart failure the venous pulse affords information of a kind entirely different from that supplied by other means. Its appearance, increase, decrease, and disappearance may give evidences of changes in the blood-pressure quite inappreciable by any signs given by the arterial pulse. While, as a general rule, an increase of the venous pressure implies a diminution of the arterial pressure, that, nevertheless, is not always the case. Although in some cases the disappearance of the venous pulse is a sign of the restoration of the body to a healthier condition, yet in other cases it may precede a fatal termination. In these last cases there is also a failure of arterial pressure. In pulse irregularities no true knowledge of the action of the different chambers of the heart can be obtained except by the study of the venous pulse, and this study, says the author, throws a new light upon the heart's movements, and reveals a variety of them hitherto unsuspected.—*New York Medical Journal.*

Obliteration of the Superior Vena Cava.—According to the Paris correspondent of *The Lancet*, Dr. Merlin has published the details of a case of plugging of the superior vena cava—a very rare phenomenon; but what constitutes a still greater rarity is the recovery of Dr. Merlin's patient, who has since (a space of four years) remained well. His patient was a man, aged thirty-four, who, after an effort, was affected with a swelling of the face which, spreading to the whole head, rendered it of an enormous size. The cheeks were puffed out, œdematous, the eyes bulging out of the orbits, the lips (especially the lower) double the normal volume, the tongue swollen so that the mouth could hardly contain it, and articulation was difficult. The œdema of the neck was great, the circumference having increased from thirty-nine to fifty-six centimetres. The jugular veins were dilated, and the establishment of collateral circulation was apparent from the presence of varicosities at the base of the neck. The œdema was marked as low down as the base of the thorax, and the patient had attacks of dyspnœa. The voice was cavernous, cough was frequent, and deafness was complete. The upper extremities were much less swollen than the face or trunk. Below the umbilicus there was no œdema. The patient denied having had syphilis. He was, nevertheless, ordered one drachm of potassium iodide *per diem*, with the result that considerable improvement began as early as the second day. The improvement continued progressively, and he was discharged in a month cured. As above mentioned, the recovery has been since (for four years) maintained.

Suprarenal Tumor.—According to the Berlin correspondent of the *Medical Press* Dr. Lazarus showed a preparation before the Gesellschaft taken from a child, aged three and a half, which had been received into hospital in the middle of February. According to the mother's story the disease commenced with pain in the body, which soon began to swell. In the right upper part of the abdomen a firm, hard swelling was found, which was taken for disease of the liver. The lungs, heart, and kidneys appeared to be healthy; the child became feeble and pale, the hæmoglobin of the blood fifty per cent., and at no time in the history of the case was there fever. Repeated punctures from the margin of the ribs to the umbilicus, over the region of the swelling, emitted very little fluid, of which the microscopical examination gave no confirmation of a malignant character. Closer diagnosis revealed a renal tumor. The child rapidly emaciated, while the weight of the body as quickly increased, till, eight days after admission, it died. On section the abdomen was found to be filled with a tumor; the total weight of the child was thirty-seven pounds, the tumor alone twelve pounds, which originated from the left suprarenal body, which was firmly adherent to the cortical surface of the kidney. The small bowel was pressed upward and backward, the stomach and large intestine were crushed into a small space on the right side of the diaphragm. During life no discoloration of the skin was present. Over the surface of the tumor small nodules were found rising in knots, which, on examination, proved to be sarcomatous degeneration. The liver appeared as a sheet of paper enveloping the tumor.

MEDICAL RECORD:

TYPHUS AND TUBERCULOSIS.

AT a recent congress of hygiene in France, two important subjects received special attention: the spread of contagious diseases, especially typhus and small-pox, by tramps and other vagabonds; and the social as distinguished from the hereditary causes of tubercular consumption, this disease being probably the greatest physical evil known to humanity.

Typhus had been practically absent from Paris for seventy years, until last year, when tramps brought it into a night refuge at Amiens. It soon spread to other institutions and to the soldiers' barracks, in spite of energetic disinfection and segregation. This year it has appeared as virulently as ever, and is tending to become endemic in France. Deschamps read the first paper on the subject of typhus, stating that, unlike most epidemic diseases, this is one which easily attacks persons in perfect health and without physical defect or predisposition, ending mortally with them oftener than with those of weakened or inferior constitutions. The tramp who has not as yet the slightest exterior or visible symptom of typhus may already give it to those with whom he comes in contact or leave it behind him in the night refuge, especially during the ten or twelve days before he finally comes down with the disease. Contagion is ever to be feared when cure seems to be complete. Dronineau spoke of the tendency of typhus to fix itself permanently in a region to which it once gains admittance. It was thought best, however, by others, not to suppress the night refuges, as these combine public safety with public charity. Constructed of brick or stone, with framework and furniture exclusively of iron, such refuges could each morning be thoroughly disinfected and the straw of the floor and beds be burned. In concluding, the association decided to ask the ministers of the interior and of agriculture, that sanitary inspectors, both of men and beasts, might enjoy permanently the powers now granted them only during a period of a declared epidemic. Republican France accepts the duty of sheltering its vagabonds, and should also have the right of preventing the contagion of disease to its citizens.

An interesting feature of the meetings was a paper by Tison on pulmonary tuberculosis, to which he attributes one quarter of the whole number of deaths in Paris and in other large cities everywhere. At once infections and contagious, very difficult to expel when it has once invaded the organism, tuberculosis remains the cause of death that science has least succeeded in mastering. The preventive measures that might be taken by society, correspond to the three great social causes of tuberculosis as distinguished from hereditary predisposition. These are "troglodytism," alcoholism, and excessive labor, three influences most at work between the ages of eighteen and forty-five. Troglodytism is that condition of modern society that lodges human beings in small rooms, insufficiently supplied with pure air and light, similar to the cave dwellings of the prehistoric troglodytes, with advantages on the side of the cave dwellers. They crept into their holes only to sleep or to shelter themselves from storm or attack, spending most of their time hunting and fishing in the open air. The modern cave-dweller spends most of his time in a luxurious hole or apartment house, and but little, comparatively, outside in the open. Alcoholism, as a cause of pulmonary tuberculosis, must not be confounded with drunkenness, which is uncommon in France. By alcoholism, Tison means that light but constant sipping of liquors and brandy, especially before and after meals, which daily comes more and more to prevail among the men and women of France. In nearly all of these drinks there is from fifty to seventy per cent. of pure alcohol; and even when water dilutes them, more alcohol enters the system than can well be borne. Modern chemists find that alcohol does little more than pass through the system without change or assimilation, remaining as a clog to liver or brain when not eliminated. Even when it has disappeared, a morbid condition of the organs by which it is eliminated remains. The forced elimination of alcohol by the lungs is a direct cause of pulmonary tuberculosis. The physiological impoverishment resulting from insufficient nourishment, Tison states with much bitterness, is due largely to the adulteration of important articles of food and drink. In ordinary canned goods there is only a trace of genuine food. Modern legislation allows the counterfeiting of food and drink, and punishes severely the counterfeiting of money. When the public health is considered as important as the public purse, there will be less pulmonary consumption.

A PRIVATE AMBULANCE SERVICE.

IN this city all the ambulance service has been furnished by the public or private hospitals. The city is divided into districts, and connection with the hospitals and police stations is established by telegraph and telephone. The system works well, though at times the service is slow. When a person who is very ill needs some conveyance to his home or a private hospital he has usually to go to some of the large hospitals and hire an ambulance for his purpose. This is expensive, and often slow and annoying. There are, we believe, some specially arranged carriages by which an invalid can be conveyed from the ferry or a train to his destination. Recently an enterprising firm has undertaken to establish a private ambulance service which may be called upon at any hour of the night or day for the convenience of small institutions or physicians in private practice. Already we are informed that some of the private hospitals are using this service, and as its rates are much more reasonable than those of the public ambulances, it seems as though it would supply a demand.

SNAKE-POISON A TOXIC PROTEID.

In *Science Progress* for September, W. Halliburton has a most interesting paper on snake-poison. Not the least strange of the many puzzling facts in connection with the proteids, says the author, is that many of them are poisonous. The proteids are the most important class of chemical substances, forming the most essential of the constituents of a diet, and are the most constant and abundant of the materials obtainable from protoplasm and living structures generally. Yet practically nothing is known of their chemical constitution. The poisonous proteids are not distinguishable by any well-marked or physical properties from the non-poisonous or food proteids. Both animals and vegetables furnish poisonous proteids; notably jequirity seeds and the yellow lupin in the vegetable kingdom, and snake-poison among animals, together with the proteids in the serum of the conger-eel and other fish, and the proteid poisons found in certain spiders. Proteid poisons are also formed during ordinary digestive processes in the human alimentary canal, from the proteids taken as food. Normally animals are protected from this poison by the lining membrane of the alimentary tract, so that no proteose or peptone is found in blood or lymph during the most active periods of digestion. The cells of this membrane possess many remarkable properties, but one of the most important is this power of regenerating albumin from peptone.

Allied to the albumoses of ordinary gastric activity are the similar products produced by bacteria. In some cases poisons produced by the growth of micro-organisms are alkaloidal in nature. In by far the greater number the toxic product is a proteid. There is still another important class of proteid poisons, the nucleo-albumins obtained by suitable methods from most of the cellular organs of the body. Out of all the work necessary to make the foregoing discoveries, the practical recognition of the alexines or protective proteids has been reached. These alexines appear to belong to the nucleo-albumin class also. In small doses they confer immunity on animals to large doses of similar poisons. The long hidden secret of the *modus operandi* of vaccination and other forms of protective inoculation begins at last to be revealed.

The small quantity of poisonous proteid that the snake secretes is atoned for by its quality. One thousandth part of a grain of the Australian black snake's poison invariably kills a rabbit five pounds in weight in about a hundred seconds. And this deadly proteid is as yet undistinguishable by chemical methods from those in daily use as foods!

In the researches on the venom of the Australian black snake, Martin and Smith found it necessary to exclude various classes of poisons, as well as to determine positively the nature of the venom. They excluded in the first place by appropriate experiments the presence of micro-organisms, ferments, alkaloids, ptomaïnes, and crystalline acids. Next they showed that the poison itself was a proteid mixture, containing three distinct proteids, one an albumin, and the other two albumoses. The albumin is not virulent, but the two albumoses (corresponding to proto- and hetero-albumoses of Kühne) are extremely poisonous. They each have the same physiological action, and this is the same as that produced by the venom itself. Momentary boiling of the venom does not impair its activity, but prolonged boiling for days destroys its virulence.

The most marked local effect of serpent proteid poison is œdema. The general symptoms consist of twitching and convulsions in non-lethal doses. Continued fluidity of the blood has been noted by numerous observers in the case of various snake-poisons. Martin found that different doses produced different results; and these results show a great resemblance between the action of the venom and that of tissue-fibrogen and nucleo albumin. Does the poison contain nucleo-albumin, which itself is a proteid united to a substance rich in phosphorus called nuclein? Snake-venom contains no nucleo albumin; and its action not only opens up a novel aspect of the subject of snake-poisoning, but also sheds light on the vexed question of blood coagulation.

GRIEF, EMOTION, AND INFECTION.

Many violent maladies have been supposed to have been produced under the operation of moral influences. Fear has been considered capable of provoking erysipelas. Laënnec believed that griefs and annoyances were important constituents in the frequency of tuberculosis in large cities. Reproaches and agitation have been known to be shortly followed by puerperal infection, in cases that were doing perfectly well up to the untimely interference of parents or relatives. Many observers, according to Fèré, in the *Popular Science Monthly*, for January, attribute an important part in the etiology of the diseases of women in child-bed to moral affections. Theories recently put forth to explain contagion and immunity from infectious disease seem to agree with the facts in the case. One, that mesodermic cells are charged with the protection of the organism, explains why diminutions of circulation and decrease in the calibre of the blood-vessels is necessarily unfavorable to the sally of protective cells and phagocytosis. Asthenic emotions, from this point of view, lead to the same condition as traumatism, fatigue (Charcot, Boyen); chill (Pasteur, Wagner, Platania, Chairin); inanition, (Canalis, Morpurge); loss of blood (Serafini); and nervous sections (Ruffer, Roger, Herman).

That grief prostrates, often causing physical disease and sometimes death, has long been a matter of everyday knowledge. The way in which such effects are brought about has been the subject of careful study by an investigator named Bassi, who has recorded observations on animals which apparently died in consequence of capture. Birds, moles, and a dog, finally succumbed to conditions that correspond in the human animal to acute nostalgia and a "broken heart." These humble cousins of the human race were examined post mortem.

Generally there was hyperæmia, says *The Lancet*, sometimes associated with capillary hemorrhages of the abdominal organs, more especially of the liver, with fatty and granular degeneration of their elements, and sometimes bile was found in the stomach with or without a catarrhal condition. The clinical symptoms were at first those of excitement, especially in the birds, and followed by depression and persistent anorexia. The theory suggested by Dr. Bassi is that the nervous disturbance in-

terferes with the proper nutrition of the tissues in such a way as to give rise to poisonous substances—ptomaïnes—which set up acute degeneration of the parenchymatous elements similar to that which occurs in consequence of the action of certain poisonous substances, as phosphorus, or to that met with in some infectious disease. In support of this view, it may be remembered that Schule earlier found parenchymatous degeneration in persons dead from acute delirium, and that Zenker found hemorrhages into the pancreas in persons who had died suddenly.

MENTAL SEDATIVES.

THOUSANDS of men and women, says the *London Spectator*, use novels as mental sedatives, read them to steady their nerves. Busy brain-workers, or those who otherwise exhaust their nervous energies, want some form of mental sedative. They cannot rest while doing nothing. In order to quiet the thinking machine, it must be kept gently at work. The easier and more mechanical that work is the better, but the mental powers must just be kept running. A douche of fiction quiets them, so novels are poured over the weary in a gentle easy stream. This physical need creates the novel market. To one accustomed to use fiction to soothe his mind, there comes a positive craving for novels, like the craving for any other sedative. Hence the demand for fiction, good or bad, of a kind that does not obtain in other forms of literature. And if the novel is in a foreign language, be it said in passing, the sedative effect is complete.

News of the Week.

The Progress of Medicine in China.—The Viceroy Li Hung Chang has established in Tientsin an imperial medical college, with a staff of western (English) medical men who assist native Chinese in teaching. A four years' graduated course is required and a well-equipped hospital has been built.

Cesario's Body.—Professor Lacassagne applied to have Cesario's body, in order to make a post-mortem examination. Menacing letters, it appears, were sent to the medical faculty, and the body has been buried. Thus probably interesting pathological and physiological data have been lost, and it is shown that the anarchist does not favor scientific any more than he does social progress.

On the Use of Cinnamon and Other "Cures" for Cancer.—Mr. J. W. Hulke writes to *The Lancet* that a regulation of the Middlesex Hospital respecting its in-patient cancer wards requires the surgeons in charge of these to try every alleged remedy the composition of which is not "secret" and for which obviously there are not sufficient grounds for judging that its effect, if any, will be injurious. A letter from Dr. J. Carne Ross having been published in *The Lancet* on the great value of cinnamon in cancer, it was agreed to try the drug in the way recommended. Five cases were chosen as best fulfilling the conditions under which Dr. Ross had obtained the best results. Three were uterine cases, one was rectal, and one was a case of recurrent masses in the neck everywhere covered with sound skin. The preparation used was made by slowly boiling one pound of Ceylon sticks with three pints of water till the bulk was reduced to one pint. Half a pint was drunk daily. Four of the patients were under observation in the hospital the whole time; the fifth patient was treated for part of the time as an out-patient. In four of the cases administration was continued for between two and three weeks, after which the drug became intolerable to the patient and was vomited. The patient in the fifth case continued to take it for a month before he begged to have it changed. In three of the cases there was definite evidence of increase of the growth during the administration. In none was there any evidence of relief of the pain, and in no case was it possible to diminish the dose of morphia or opium, but rather this had to be increased with the increase of the growth or as the drug lost its power from custom. Mr. Hulke adds: "It has fallen to me to make trial of various remedial measures, suggested here and abroad for the relief and cure of sufferers from cancer, in the course of some twenty-five years or thereabouts. Of such "pharmaka" I may mention "Fells' paste" (the active ingredient in which is zinc chloride colored with red snakeroot), slow injection of acetic acid through a capillary tube, sundry escharotic pastes and powders having arsenic as their essential component, condurango, and more recently Chian turpentine; also besides these the dietetic treatment laid down by Beneke, without and with the association of arsenic administered internally recommended by Esmarch. Several years ago the conjecture that cancer might have a parasitic origin induced me to try cinnamon, being influenced in the selection of this by the common ascription of germicidal properties to aromatic oils, and by my recollection that my old teacher, Dr. A. Farre, held strongly that cinnamon had something like a specific or particular influence over some uterine functions, a belief which led him to prescribe large doses of the tincture in certain cases of dysmenorrhœa. I gave cinnamon a long trial, chiefly in cases of cancer of the uterus, but also in that of other organs. The result was wholly negative.

The Craig Epileptic Colony.—Dr. Frederick Peterson, President of the Board of Managers of Craig Colony, writes that our informant was in error in the statement, recently published in these columns, that the epileptic colony would not be opened under two or three years. The colony will be opened for actual work, he says, next spring. "There are six hundred patients eagerly waiting in the almshouses of the State to patronize the colony; besides which the managers are receiving daily letters from numberless unfortunates, not in almshouses, anxious to enter the colony as soon as they can be received."

Dr. George W. Davis, of Holyoke, Mass., died in that city, on September 18th. He was born on March 26, 1847, and was graduated in medicine from the Vermont University in 1868. He began practice in Craftsbury, Vt., but removed to Holyoke in 1871 where he resided continuously up to the time of his death. The cause of his death was disease of the heart following an attack of influenza in 1892.

A New Charity has been organized at Brooklyn, known as the Non-Sectarian Hospital and Home for Epileptics, having accommodations for forty inmates.

The New York State Association of Railway Surgeons.—The annual meeting of this Association will be held at the Academy of Medicine, in this city, on November 15th next. All railway surgeons of the State are invited to be present. The Secretary of the Association is Dr. J. B. Hulett, of Middletown, N. Y.

The Southern Surgical and Gynecological Association.—The Seventh Annual Session of this Association will be held in Charleston, S. C., on November 13th, 14th, and 15th. Papers will be presented by a number of the leading surgeons and gynecologists of the South. The medical profession is cordially invited to attend. The President of the Association is Dr. Cornelius Kollock, of Cheraw, S. C.

Dr. Albert H. Buck, of No. 14 East 45th Street, New York, writes: "On page 810 of the MEDICAL RECORD (issue of June 30, 1894), I speak of Dr. Frederic Lange, the distinguished surgeon of this city, as Dr. Theodore Lange. You will do me a favor if you will insert a suitable correction of this error in one of the next issues of the MEDICAL RECORD.

The Malarial Organism in the Blood Plaque.—Dr. George J. Preston, of Baltimore, writes: "In examining the blood of a considerable number of malarial cases this summer, I observed quite frequently a speck of pigment in the blood plaques. Careful observation showed beyond any doubt that this pigment possessed motile properties. Generally there was but one clump of pigment, occasionally two or three granules. At first the single granule was mistaken for a nucleus, but it was soon noted that the supposed nucleus moved from one part of the plaque to another. The movement is not the rapid zigzag motion of the free malarial organism, but a much slower motion. The pigment can be seen to slowly change its place in the plaque, now in the centre, now at the periphery. In patients taking methyl blue the pigment was slightly stained. The organism was observed most frequently in the blood of patients taken during the chill or a few hours before or after the paroxysm. It was seen, however, sometimes in the interparoxysmal period. The physiology of the blood plaque is still so uncertain that this note is recorded in the hope that further observation may confirm the presence of the malarial organism in this structure."

The American Medical Publisher's Association.—The first annual meeting occurred at Hot Springs, Va., on August 13th and 14th. After the transaction of the usual routine business, the president, Dr. Landon B. Edwards, read a paper on "Advertising and Advertising Agencies." Upon motion, it was decided that all annual meetings hereafter should be held just prior to the sessions of the American Medical Association, the next meeting being set for Monday, June 5, 1895, at 9 A.M., in the Utah House, Baltimore.

Dr. Charles H. Dare, of Bridgeton, N. J., died on August 25th. He was for seventeen years County Physician, and was Surgeon of the Fourth New Jersey National Guard.

A Worm Specialist on Third Avenue advertises to remove the worm, head and all, in two hours. This hardly gives tænia solaris, which is naturally a slow animal, a fair show.

Dr. Jacob Newkirk, of Binghamton, N. Y., died August 13th, aged eighty-nine.

Dr. Charles H. Williamson, formerly a surgeon in the United States Navy, died at St. John's Hospital, Brooklyn, N. Y., in the sixty-ninth year of his age. He was a native of Portsmouth, Va., and a graduate in medicine from the University of Pennsylvania.

Railway Accidents.—From the advance sheets of the Statistics of Railways in the United States prepared by the Interstate Commerce Commission for the year ending June 30, 1893, the following statistics are prepared and published in the *Railway Surgeon*.

COMPARATIVE SUMMARY OF RAILWAY ACCIDENTS FOR THE YEARS ENDING JUNE 30, 1893, 1892, 1891, 1890, 1889, AND 1888:

YEAR.	EMPLOYEES.		PASSENGERS.		OTHER PERSONS.		TOTAL.	
	Killed.	Injured.	Killed.	Injured.	Killed.	Injured.	Killed.	Injured.
1893..	2,727	31,729	299	3,229	4,320	5,435	7,346	40,393
1892...	2,554	28,267	376	3,227	4,217	5,158	7,147	36,652
1891...	2,660	25,140	293	2,972	4,076	4,769	7,029	33,881
1890...	2,451	22,396	286	2,425	5,598	4,206	6,335	29,027
1889...	1,972	20,028	310	2,146	3,541	4,135	5,823	26,309
1888...	2,070	20,148	315	2,138	2,897	3,632	5,282	25,888

A Hopeful Candidate.—A late applicant before the Texas Examining Board was asked: "What is histology?" "Histology is the history of medicine."

"What system of medicine do you practise?" "The Vanderbilt and St. Louis systems, and sometimes the homeopath system."

"What is the homeopath system, as you call it?" "Sweatin' the patient."

The Abuse of the Reprint.—It is a courteous and commendable custom for an author who has written an article of real value to send reprints thereof to libraries for reference, to his friends for preservation, and to those pursuing the same line of investigation, who might not otherwise become so soon acquainted with his researches. When, however, the reprint is used merely to advertise the fact that the writer is peculiarly skilful in a certain specialty it is less commendable; and when it is used to advertise Messrs. Enterprise & Paywell's Panacea, or some similar substance, it becomes anything but commendable. These thoughts are suggested by the receipt of a pamphlet, reprinted from a journal published in a neighboring city, and bearing the title "Functional ———," by X. Y. Z., M.D., Professor of ——— in the ———, etc., which publication, although ostensibly coming to us from the author, is quite evidently circulated as an advertisement by, and at the expense of, the firm whose "trade-mark" product is therein recommended (no doubt honestly) as a sovereign remedy for the affection in question. Apart from all questions of propriety, men who permit their names thus to be misused are very shortsighted. Their advice, however unjustly, comes to be looked upon with suspicion, as not wholly scientific and disinterested; and their reputation becomes upon a par with that of the "advance-agents" of theatrical notorieties—an honorable reputation when one does not pretend to be other than an advance-agent. The advertising-reprint and the reading-notice are twin growths of the same poisonous root, and should be utterly condemned by thinking, self respecting physicians.—*Medical News.*

Clinical Department.

SECONDARY SUTURE OF THE SCIATIC NERVE.

By LEONARD FREEMAN, M.D.,

PATHOLOGIST CINCINNATI HOSPITAL; SURGEON TO CHRIST'S HOSPITAL, CINCINNATI, O.

On July 19, 1889, a colored boy, aged nineteen, was brought to the Cincinnati Hospital suffering from a cut across the left thigh. The incision, which reached to the bone, began about two inches below the trochanter major and extended backward and downward for a distance of about five inches. The wound soon healed, but, according to the history of the case, sensation remained absent in the foot and the limb could not be used freely.

On August 15, 1891, he again entered the hospital, about twenty-five months after the original injury. Paralysis and atrophy of the muscles of the leg and foot were present, with some atrophy of the thigh. Sensation was absent on the entire outer side of the leg and on the sole and dorsum of the foot, except in a line about one and one-half inch broad along its upper and inner aspect. The anæsthetic area was dry and covered with a scaly, whitish epithelium, and was separated in a beautifully distinct manner from the adjacent soft, dark, and moist skin. There was œdema of the foot, and the nails of two or three toes were missing. A large, deep, trophic ulcer occupied the under surface of the heel.

It was difficult to make the man understand that there could be any connection between the injury to his thigh above and the trouble in the foot below; he suspected that we wished to "experiment" on him. Finally he consented to an operation, and about twenty-seven months after its division the sciatic nerve was reunited with sutures.

A longitudinal incision six inches in length was made, with the line of the old cicatrix as a centre. The inferior segment of the nerve, owing partially to its atrophy, was found with some difficulty. The superior segment revealed itself at once by the spindle-shaped bulbous enlargement, the size of an English walnut, which occupied its extremity. This was removed by a wedge-shaped incision with its apex well within the normal nerve above. Below the old injury the nerve was much atrophied, its fibres spreading out and losing themselves in the cicatrix. These stringy fibres were separated as thoroughly as possible from the surrounding tissues, and the end of the nerve resected. The distal and proximal nerve-sections were then repeatedly and forcibly stretched with as much force as was considered safe, in order to bring them closer together.

On flexing the knee and extending the hip it was possible to approximate the ends of the divided nerve, the separation between which had at first been at least four inches. Cat-gut sutures were employed, some being tied to portions of the neurilemma and others introduced through the body of the nerve itself, the end of the distal segment being dove-tailed into the V-shaped incision in the end of the proximal segment.

The operation and subsequent dressings being conducted with aseptic and antiseptic precautions, the wound healed by first intention, the knee being retained in flexion and the hip in extension by plaster of Paris.

On the third day following the operation, wishing to demonstrate the absence of sensation in my patient's leg, I suddenly stuck a pin into the part. The result was startling; the man gave a yell, and raised very pointed objections to a repetition of the experiment. This was the first intimation which we obtained of returning sensation.

On the eighth day, quoting from the history, "sensation is greatly increased," and "the scaly appearance of the skin over the entire leg is disappearing, and the cuticle approaching more nearly its normal condition. The ulcer on the foot is healing steadily."

In two weeks, during which time sensation gradually returned to the leg, the plaster splint was removed and the patient instructed to straighten his limb slowly and carefully, a little each day. On the outer surface of the foot, and more especially about the little toe, the power of feeling remained markedly deficient.

In seventeen or eighteen days the history reads, "sensation is gradually passing to the foot, and now deep prickings with a pin can be felt in the little toe." In about three weeks the patient was walking about on crutches. In a month from the date of the operation the skin of the leg had recovered its softness and smoothness, and had almost returned to the normal, while the ulcer was nearly healed. Sensation having become even abnormally acute in places.

At the end of about five weeks the patient insisted on leaving the hospital. He could walk well without the use of crutch or cane, the ulcer was healed, and the skin of the leg nearly normal. There was some sensation in the foot, although very deficient on the outer border, but sensation in the leg was nearly what it should be. The muscular paralysis, however, had improved little if any.

In July, 1892, nearly a year after the operation, the patient was again in the hospital. The ulcer on the foot was present, although, as near as could be ascertained, it had healed and broken out several times. Unfortunately nothing was mentioned in the history as to sensation or motion in the foot.

On May 24, 1894, the patient was again examined. The leg above the ankle was perfectly normal; the skin being soft and moist and the sensation perfect. The foot, however, was in bad condition—a large and deep ulcer occupied the posterior surface, while another smaller ulcer had appeared on the outer edge of the foot near the little toe. In fact, the condition of the foot was such that amputation was resorted to in order to rid the patient of his incumbrance.

After a careful search of all the literature at my disposal, I have been able to find but three other cases of secondary suture of the sciatic nerve—although there have probably been others—one by Welhouse and one by Langenbeck, in 1876, and one by Weir, in 1882. Wyeth, although he did not suture the sciatic itself, reunited to that nerve the severed internal and external popliteals.

Langenbeck's operation was made two and a half years after the injury to the nerve; and, similarly to my own, was followed by a return of sensation on the third day. The patient, a man, aged nineteen, had motor paralysis in the leg and foot, together with anæsthesia of the area supplied by the sciatic. A large, deep ulcer existed near the base of the fifth metatarsal bone. The operation-wound healed by second intention. The ulcer filled up rapidly, and sensation returned steadily to the parts, some portion even becoming hyperæsthetic.

At the end of a year the patient was again seen. Motor paralysis was still as complete as before the operation. Considerable of the sensation which had been gained was found to have again disappeared, although a certain amount of improvement remained, and the ulcer had not broken down.

In Wyeth's case the popliteal nerves were sutured to the sciatic ten weeks after the injury. Sensation began to return in five days, and was almost fully restored at the end of twenty-two days. The ulcers which had appeared on the foot healed rapidly. After two months, sensation still existed in the part, accompanied by considerable pain. The subsequent history is not given.

In Welhouse's case complete paralysis of the sciatic followed an injury to the left thigh just below the gluteal mass. He operated nine months after the injury, the wound healing in two or three weeks. The first few signs of returning sensation and motion did not occur for three months, and it required two years for the leg to

regain its original usefulness. At the end of that time only a slight œdema and a subnormal temperature remained of the original disturbance.

Weir sutured the sciatic nine years after its division. There was no gain in motility, but some in sensation, and great improvement in the trophic changes, which had progressed to ulceration.

It strikes one in this connection that too much stress should not be laid on the healing of ulcers, because confinement to bed after an operation must have a tendency in itself to produce improvement.

Considering the history of my own case and that of Langenbeck, it seems reasonable to suppose that the ultimate disappearance of sensation which had reappeared following the operation might have been due to pressure on the nerve from cicatricial contraction. This view is strengthened by a case reported by Tillaux, in which suture of the median was followed by restoration of function which subsequently disappeared. A second operation revealed a cicatricial mass pressing on the nerve, the removal of which rapidly restored the lost functions. Pye describes a similar case. I have myself seen in a case operated upon by Dr. Dandridge the removal of a cicatricial band, which pressed upon a nerve, greatly benefit the motor and sensory disturbances which had resulted.

Where there is much danger of such cicatricial contraction, might it not be practicable, at least in regard to the deep-seated sciatic, to conduct the sutured nerve over the dangerous region through a suitable aluminum or other light, non absorbable, non-compressible cylinder? Aseptic bodies, such as drainage-tubes, bullets, gauze, wire, etc., heal into the tissues without any difficulty or irritation, even splinters of wood sometimes do this, and there seems to be no reason why an aluminum cylinder should not do the same. In addition, Gluck asserts that nerves regenerate more rapidly over long distances when their severed ends are connected by a bone drainage-tube. Vaulair mentions a case in which a regeneration of two inches was thus obtained after a lapse of four months, the new nerve-substance originating by a process of proliferation from the end of the proximal segment alone.

The suturing of nerves, although rather a recent surgical procedure, has been done a great number of times, especially in connection with the median and ulnar; and the results, particularly if the operation is undertaken at the time of the injury, or soon afterwards, are generally excellent. But in cases where weeks, months, or even years have elapsed the chances of success are not so good. Successful cases have been recorded, however, after a great lapse of time. Jessup, for instance, operated on the median nerve nine years after it had been divided, and succeeded in obtaining restoration of function.

F. J. Hodges has collected 108 cases of secondary nerve-suturing, including Brun's 33 cases, with eighty-eight per cent. of successes. This percentage is probably too high. There are a number of reasons why it is easy to be mistaken in the assumption that reunion of a divided nerve has taken place. It must be remembered that there is such a thing as anastomosis of nerves as well as of arteries, and that these anastomotic filaments may take on the sensory functions of the injured nerve. The areas of innervation of nerves also at times overlap each other to a greater or lesser extent, so that sensation is only slightly or temporarily interrupted by division of a nerve-trunk. It has been asserted by Brown-Séquard that irritation of the proximal end of a divided nerve, such as would result from an operation, would so stimulate the spinal centres that a reflex and heightened sensibility would be communicated to alien filaments going to the anæsthetic area, leading the operator to think that the nerve operated upon had been reunited.

It is of course possible that something of this sort may have taken place in either of the cases described above. In such a process as that just mentioned motion is not apt to return to any marked extent, even though the restoration of sensation be complete. As regards motion, deception is easy. Patients become, in the course of time, quite expert in overcoming the loss of power in a set of muscles, by the use of others. Also the natural elasticity of the tissues, especially when aided by contractures, may cause movements which seem as if produced by nerve action. For instance, if the flexors of the hand are paralyzed, the opposing muscles will extend the fingers, which may partially flex themselves again simply from elastic contraction of the muscles and tendons. A reliable sign of nerve regeneration is probably the return of the faradic excitability of the muscles.

It is a common thing for sensation to return first, followed after a time by motion. Motion may not appear at all, or only after the lapse of weeks, months, or even years, and then it may be but partial. The case may improve for a time, and then grow progressively worse; which may be due occasionally, as I have stated, to cicatricial contraction. Absolute failure cannot be declared, however, until two or three years have elapsed.

It is truly astonishing how soon sensation will sometimes reappear. Tillaux states that following suture of the median four years after its division all the functions of the nerve reappeared in three hours; and we read of cases of immediate suture in which recovery of function took place within fifteen minutes, or even as soon as the nerve ends were approximated (Segond).

Catgut is probably the best material to employ, although silk and even silver wire have been used. The suture may pass directly through the substance of the nerve, in which case, for obvious reasons, a Hagadorn needle is better than one with sharp edges; or they may include only the neurolemma. In the latter method a small portion of the sheath may advantageously be caught in a knot on either side, so as to prevent tearing out of the thread. Or both these methods may be employed in conjunction, which seems to be ordinarily preferable, as it permits of accurate adjustment of the divided surfaces, and at the same time gives considerable strength to the union.

In case the ends of the divided nerve have contracted too far to be easily brought together, one of several expedients may be adopted: Gluck has suggested that the extremities of the segments be connected by a section of decalcified bone drainage-tube, in order that the nerve may regenerate along its lumen. By use of this procedure Vaulair succeeded in obtaining a regeneration of two inches after four months.

Experiments have been carried out on animals which show that sections of nerves may be grafted from one animal to another, and probably from animals to man. Nerves have occasionally been successfully spliced—a flap turned down from one segment being joined to a flap from the opposing segment, similarly to the way in which tendons are spliced.

The distal portion of a divided nerve may also be grafted into the side of an adjacent nerve, or onto the proximal end of a second nerve if it be likewise divided. Good results have been thus obtained. Again, both the proximal and distal ends may be grafted onto another nerve at different levels, so as to use the latter as a conducting medium for a short distance. Billroth resected a portion of the humerus in order to bring the ends of the divided nerve closer together.

Explosive Power of Modern Bullets.—Dr. Du Bois Reymond has been making experiments to record the effect of the modern German rifle-bullet, and finds it very destructive. The bullet of the old style rifle, he says, bored only a comparatively small hole through the portions of the body through which it passed, whereas the new bullet has an astonishing explosive effect. If, for instance, the ball passes through the head of the corpse, the skull is burst asunder in all directions, and very little of the head remains. The speed of the bullet is so great that when it meets an obstacle it explodes like a Prince Rupert's drop and destroys all the tissues around it.

TUBERCULOSIS OF THE LARYNX AND PHARYNX.[1]

By FRED. S. CROSSFIELD, M.D.,

HARTFORD, CT.

I DO not propose in the present paper to bring forward new ideas respecting the theory or treatment of this form of laryngeal disease. My purpose is rather to state my experience with it, and to outline the course of treatment I have adopted, and the results that have followed.

I have selected two cases entirely unlike in their general features, and I shall give the histories of these cases in detail.

The first case is that of a young woman, aged twenty-three, American, unmarried, of slight build, employed in a silk mill. She was brought up amid the most favorable hygienic surroundings, and her health had always been good. There was nothing unfavorable in the family history. Her father, mother, brother, and two sisters were living, and in good health.

She came to me with the following history: In the month of May, 1886, at the age of eighteen, she was injured by a runaway horse. She was thrown some distance, striking upon the side of her head; the injury caused concussion of the brain and meningitis followed. This sickness lasted three months, at the end of which time, having regained her health, she went back to her work in the mill. About three months afterward she took a severe cold, and from that time her health failed. Aside from a sense of continued fatigue, she complained only of her throat, where she felt a constant burning irritation with a desire to cough, but no expectoration. Deglutition produced but slight discomfort. Her throat was not examined at this time. Her physician told her she was overworked and run down, and advised her to go to Vermont for a change. She deferred the trip, however, until June of the following year, 1887. Meanwhile the discomfort in the throat increased, dysphagia being added. She remained in Vermont thirteen months. Soon after her arrival improvement began, and it continued during her stay. Her weight increased from 88 pounds to 108½ pounds. The throat difficulty entirely disappeared, and she says she felt perfectly well.

Three months after returning to her home she resumed her position in the mill and worked steadily until June, 1891—three years. At this time there was a recurrence of the throat trouble.

I first saw her in October of the same year. Up to this time there had never been an examination of the throat, nor had she received any local treatment. Her condition was as follows: Pale, emaciated, easily fatigued, no appetite, slight rise in temperature in the latter part of the day. Deglutition was painful and a troublesome cough interfered with sleep and with the taking of proper nourishment; the expectoration at this time was muco-purulent. The voice was husky and at times lost. The lungs were repeatedly examined, but were always found free from disease.

On examination the pharynx was found to be reddened and covered over the entire surface with a thick, tenacious, ropy mucus, streaked with blood. This mucus being wiped away, several small ulcerations were noticed upon the posterior wall, hardly deeper than the mucous membrane. The larynx presented the same appearance but without ulceration. The epiglottis and vocal cords were reddened and slightly œdematous.

The patient was placed upon a nutritious diet, and cod-liver oil, iron, and wine were administered. The local treatment consisted of thoroughly cleansing the surface, and afterward applying lactic acid, twenty-five per cent. every second day.

In three weeks the ulcerations had healed, the parts had assumed their natural color, and what little œdema there was had disappeared. The voice regained its normal quality, and the appetite and strength returned. The secretions from the pharynx and larynx were examined microscopically, but no tubercle bacilli were found. I therefore considered the condition one of simple catarrhal ulceration. The existence of syphilitic taint was considered highly improbable, as the local conditions were wholly unlike those found in syphilitic lesions of the larynx. Furthermore, the social position of the family would not warrant any such supposition.

I did not see this patient again until four months later, in February, 1892. The old trouble had apparently reappeared with increased intensity. She was pale and had grown rapidly weak and emaciated. She had night-sweats, and coughed constantly, the expectoration being tenacious mucus. The voice was now entirely lost. The pain in swallowing was severe, and her sleep much disturbed. In fact, the general condition was discouraging in the extreme. The pharynx was one mass of ulceration, from a point a little below the uvula down and into the larynx. The ulceration was shallow—but little below the surface—and covered with a grayish, tenacious mucus. The epiglottis was enlarged by infiltration to twice its normal size, and ulcerated nearly its whole length. The arytenoids were also infiltrated and ulcerated. An imperfect view only could be had of the vocal cords. Though œdematous, I do not think they were ulcerated. The entire surface of pharynx and larynx had a peculiarly blanched and sodden appearance.

The lungs were examined carefully at different times, always with the same negative results; but microscopical examination of the secretion from the pharynx now showed unmistakable signs of tuberculosis. Cod liver oil and iron were administered as before, and inhalations of oxygen were given frequently. The surfaces were thoroughly cleansed, and the ulcerations were curetted after applying a ten per cent. solution of cocaine. Lactic acid, fifty per cent., at first, and afterward undiluted, was rubbed into the surface. Several applications were required. Improvement began right away. The ulcers healed rapidly, so that at the end of six weeks healthy cicatrices marked their former location. The œdema gradually subsided and the membrane throughout resumed its normal condition and function. At the same time her general health improved.

It is now a year since cicatrization was completed, and she continues well and says she is stronger than she has been for several years. I have recently examined the throat, and could find no evidence of there having been such wide-spread destruction. I hope to be able to report favorably upon this case at some future time.

It was to me an extremely interesting case, both because the whole progress was unusual, and because it was a case of primary tuberculosis of the larynx and pharynx of extreme severity, and demonstrated what can be done, even in what would seem to be a hopeless case, toward alleviating the distress, if not absolutely producing a cure.

The second case that I shall describe was that of a printer, twenty-seven years of age, American, married. His father, brother, and one sister died of consumption, and he had had general tuberculosis himself for a year and a half previous to his coming under my care, in November, 1889, and at that time he had also been suffering for three months with throat complications.

I saw the patient at his home, he being too weak to come to my office. I found him pale, emaciated, very weak, and able to sit up only a few moments at a time. The cough was constant and painful; respirations, 40; pulse, 120; temperature, 102½° F.; voice entirely lost; dysphagia marked. The pain on swallowing was so severe that he could take no nourishment, nor even swallow the secretions from the mouth. The pharynx and larynx on inspection presented the characteristic pale, sodden appearance, and large superficial ulcers were found upon the posterior wall of the pharynx and upon the soft palate. Infiltration was everywhere present. The larynx was

[1] Read in the Section of Laryngology, New York Academy of Medicine, May 24, 1893.

œdematous and ulcerated. The epiglottis was nearly covered with ulcerations, and was so much enlarged by infiltration that no satisfactory view of the larynx and vocal cords could be had. A rhinoscopic examination showed a large ulcer upon the posterior wall of the pharynx on a level with the Eustachian orifices, and ulcers were also found upon the septum, and on the middle and inferior turbinated bodies on both sides.

Several small nodules were also seen upon both sides of the septum, but none upon the outer walls of the nose.

The prostration of the patient was so great that I did not dare to resort at once to curettement, indeed I had grave doubts that such treatment would be warranted at all. A five per cent. solution of cocaine was sprayed into the nasal cavities, pharynx, and larynx every three hours for four days, and whiskey and oxygen were administered freely. On the fifth day there was an evident improvement in his general condition, and he had taken considerable nourishment. I then ventured, after applying a ten per cent. solution of cocaine, to curette the pharynx, afterward rubbing well into the surface undiluted lactic acid. Later the ulcerations in the nasal cavities and the larynx were similarly treated. Though this procedure is usually very painful, it was not especially so in this case. Improvement began immediately, and the patient said he felt much relieved. Cicatrization was everywhere apparent, and nourishment was taken in sufficient amount, without difficulty, and with relish. He slept well and awoke refreshed. He increased in strength and was able to be up and about the house most of the day. Within four weeks the ulcerations had all healed, and the epiglottis had nearly resumed its usual size. The vocal chords were slightly œdematous, however, and the voice remained husky.

The patient gradually failed, and died from general tuberculosis five months after local treatment was begun. There was no return of the discomfort in the throat, and an examination of the throat and nose a week before death showed the membrane very free from ulceration, but in a pale, slightly œdematous condition throughout.

This case presents one especially interesting feature—the appearance of ulcers and nodules within the nasal cavities. I have never seen this condition before.

Bosworth, in his work on "Diseases of the Nose and Throat," vol. i., states that twenty-seven cases with this complication are reported in medical literature, and these, from lack of positive evidence, he reduces to twenty.

There can be no doubt regarding my second case, because abundant evidence of tuberculosis was found microscopically.

This case also demonstrates the efficacy of curettement and lactic acid, even in hopeless cases of general tuberculosis with laryngeal complication, in relieving the distress referable to the throat, and giving comparative comfort to the sufferer during the few remaining weeks of his life.

It has been said that it is only by looking backward that we can wisely look forward. It is certainly interesting to note the progress which has been made during the past few years in the theory and treatment of this disease. Some of the older writers make no mention of the tubercular form of laryngitis as a primary disease. Quoting from an article written upon this subject in 1883, it says, "Primary laryngeal tuberculosis may possibly occur, but the few claimed cases of its occurrence are at least open to doubt as to correctness in diagnosis." Another writer says: "Neither the catarrh nor the ulceration of phthisical subjects present any characteristic signs by which they could be recognized as such." Heinze, writing in 1879, states that of 1,226 deaths from phthisis 51.3 per cent. had laryngeal ulcerations. He also says that ulcerations were never found with tuberculosis of other organs when the lungs were intact.

The microscope and the demonstration of a specific bacillus make the diagnosis much less obscure. The advancement along these lines, and the knowledge derived from experimental investigation, now place these cases in the list of remediable diseases.

February 1, 1894.—The patient in the first case reported is still in good health, with no indications of a return of the laryngeal trouble.

THE RELATIONSHIP BETWEEN BOVINE AND HUMAN TUBERCULOSIS, WITH THE REPORT OF A CASE.

By W. H. SHERMAN, M.D.,

ATTENDING SURGEON TO ST. JOHN'S RIVERSIDE HOSPITAL, YONKERS, N. Y.

Veterinary Report,

By J. S. LAMKIN, D.V.S.,

YONKERS, N. Y.

GRADUATE OF AMERICAN VETERINARY COLLEGE.

The following case deserves, in my opinion, to go on record as a contribution to the important subject of the etiological relationship between human and bovine tuberculosis. The brief history herewith given is sufficient to thoroughly establish the diagnosis, and the veterinary report, in connection with that of the pathologist, would seem to indicate that the disease of the cattle bore a causative relationship to that of the young patient.

B. H——, male, aged four. Well nourished and of average size. Maternal grandfather died of phthisis some years ago. Mother died as the result of an accident. Family history otherwise entirely negative. His nurse had, about a year previously, attended her daughter who died of consumption. She did not contract the disease, however, nor did any of the servants in the house have tuberculosis in any form. The boy's previous history is good. He has slight adenoid vegetations in the vault of the pharynx, which render him prone to attacks of bronchitis. Two years ago he had a mild attack of pneumonia, and one year ago a second attack; from both of these he recovered entirely, and for one year has had no cough nor illness of any kind. His development has been good, and his growth and dentition normal. His uncooked food has all been raised on the place, and it is believed that he has never eaten raw fruit from market until thoroughly peeled.

I was called to see him on February 21, 1894, as it was observed that he walked with a spastic gait, on his toes, and that he would frequently tumble. From this time on he gradually but progressively developed the classical symptoms of meningitis, namely, spastic contraction, thickness in speech, difficulty in deglutition, loss of power to protrude the tongue, lack of co-ordination, opisthotonos, etc. On March 5th Dr. M. Allen Starr, Professor of Neurology at the College of Physicians and Surgeons, New York City, saw him in consultation, and confirmed the diagnosis of meningitis, probably tubercular.

Treatment.—Iodides and bromides. In spite of treatment the disease progressed in the usual way until death occurred on March 27th. No autopsy was allowed. During the latter part of the boy's illness, having some suspicion in regard to his milk supply, I requested Dr. J. S. Lamkin, Veterinary Surgeon, to inspect and examine the cows on the place, with the result as shown in his report hereto appended.

Veterinary Report.

On March 22, 1894, I was requested by Dr. W. H. Sherman to visit and examine three cows, which were stabled on the place of Mr. B——, Yonkers, N. Y., with a view of determining whether they were the subjects of tuberculosis. Two of these animals were the property of Mr. B——, and the third was owned by his son-in-law. The mixed milk was consumed by all the members of the household, including B. H——, a boy four years of age, who was at this time suffering from tubercular meningitis. A short time previous to my first visit the cows had been examined by a local veterinarian who gave them a "clean bill of health." The attending

physician, Dr. Sherman, being dissatisfied with this examination, as by physical examination alone it is sometimes impossible to detect tuberculosis in cattle, asked me to see the animals and express my opinion as to the presence or absence of tuberculosis.

Inspection showed that they were thoroughly well-housed, well cared for, and well-nourished.

Physical examination failed to disclose anything which could lead to any suspicion that they were other than perfectly healthy, except an enlargement and thickening of one section of the udder of one cow (No. 3). None of them were (or had been) suffering from cough, dyspnœa, or respiratory disturbances of any kind. After a consultation with the family and the attending physician it was decided to employ the tuberculin test, the writer being thoroughly impressed with its value as a diagnostic agent. Accordingly, on March 23d, the temperatures of the three animals were taken at 8.30 and 10.30 P.M. At 11 P.M., in each case, 2½ c.c. of a ten per cent. solution of tuberculin in one per cent. solution of carbolic acid was injected hypodermatically after the hair over the shoulder had been removed and the hide rendered aseptic.

The following morning (March 24th) at 6 A.M. the temperatures were again taken, and every three hours thereafter until 9 P.M.

The following table shows the results obtained:

	March 23, 8.30 P.M. Before injection.	March 23, 11 P.M.	March 24, 6 A.M.	March 24, 9 A.M.	March 24, 12 M.	March 24, 3 P.M.	March 24, 6 P.M.	March 24, 9 P.M.
	Deg. Fah.		Deg. Fah.	Deg. Fah.	Deg. Fah.	Deg. Fah.	Deg. Fah.	Deg. Fah.
Cow No. 1.—Five years of age. Pale red Alderney. Not in calf.	101.0	Tuberculin injection 2½ c.c. of ten per cent solution.	101.2	101.2	101.4	101.4	101.2	100.0
Cow No. 2.—Six years of age. Brown Jersey or Alderney. Aborted last August. Due to calve in May.	101 4	Tuberculin injection 2½ c.c. of ten per cent. solution.	101.4	104.2	106.0	104.2	104 2	104.4
Cow No. 3.—Ten years of age. Cream-colored Jersey. Aborted in December. Not in calf.	100.6	Tuberculin injection 2½ c.c. of ten per cent. solution.	100.2	102.2	105.8	104 4	104 2	103.4

March 25, 9 A.M., temperatures all normal.

These results seemed to prove that two of the three cows (Nos. 2 and 3) were the victims of tuberculosis, although this seemed difficult to believe in the case of Cow No. 2, who showed every other evidence of the most robust health. In view of the results of this test the writer communicated with the Secretary of the New York State Board of Health requesting that the Board send an inspector to condemn and destroy the two cows which reacted to the test, and recompense their owner.

As there was considerable delay in obtaining the desired permission to destroy and examine the animals post mortem, it was decided to retest all three of them. This second test was conducted in the same manner as before, except that the injection was given at 9 P.M. April 1st.

The following table shows the results obtained:

	April 1, 12 M.	April 1, 9 P.M.	April 1, 10.30 P.M.	April 2, 9 A.M.	April 2, 12 M.	April 2, 3 P.M.
	Deg. F	Deg. F.		Deg. F.	Deg. F.	Deg. F.
Cow No. 1.—Pale red Alderney.	102.2	101.2	Tuberculin injection 2½ c.c. of ten per cent. solution.	101 6	101.8	101.5
Cow No. 2.—Brown Jersey or Alderney.	101.6	101.4	Tuberculin injection 2½ c.c. of ten per cent. solution.	103.2	105.8	104.0
Cow No. 3.—Cream colored Jersey.	103.8	101.6	Tuberculin injection 2½ c.c. of ten per cent. solution.	101.2	102.4	102.2

April 3, temperatures not taken.
April 4, temperatures normal, except Cow No. 2 = 102.6° F.

It will be noticed from this table that Cow No. 3 did not present the characteristic reaction as in the original test.

On April 16th the two cows which responded to the test were slaughtered and a post-mortem examination was conducted by Dr. E. F. Brush, of Mount Vernon, Professor of Cattle Pathology in the American Veterinary College, and the writer, in the presence of several physicians and veterinarians, with the following results:

Cow No. 3 (White Cow) —The thickened mass from the udder was first removed. It apparently consisted of fibrous tissue, a few small cysts, and a little caseous matter, but no gross appearance of tuberculosis was observed.

The mediastinal glands were markedly involved, ranging from the size of a marble to that of a lemon, with cheesy degeneration well advanced. There were also tubercular masses of various sizes in the lung substance beneath the pleura.

Cow No. 2 (Black Cow) —Mediastinal glands enlarged, but not to so great an extent as in Cow No. 3, the largest mass being about the size of a large marble—caseous degeneration well under way.

Small nodular masses in lung under pleura with cheesy centres. On section the lungs were found to be studded with tubercles in various stages of development. Liver and kidneys not involved in either cow. Specimens from the mediastinal glands and lungs of both animals, and a portion of the mass from the udder of No. 3, were submitted to Dr. George A. Tuttle, of New York, Pathologist to the Colored Home and Hospital, for microscopical examination.

His report is here appended.

"NEW YORK, May 1, 1894.

"DEAR DOCTOR:—The examinations of the pieces of tissue from the two cows resulted as follows:

"WHITE COW, No. 3.—Lung: A cluster of tubercles about the size of large peas in and beneath the pleura. The centres of these tubercles consisted of soft cheesy material. Microscopic examination showed minute tubercles in various stages of development. Tubercles consisting of epithelioid cells and giant cells. Older tubercles with considerable fibrous tissue and with tubercle tissue and giant cells around the edges; and others with cheesy centres and tubercle tissue and giant cells around the edges. Tubercle bacilli found in moderate numbers.

"Mediastinal gland, about the size of an egg, consisted of a thickened capsule containing a mass of soft, yellow, cheesy material. Sections of the capsule showed tubercular inflammation, tubercles with cheesy centres, and epithelioid cells and giant cells. Not examined for tubercle bacilli.

"Udder contained several cheesy nodules. Sections through these showed considerable diffuse inflammation and infiltration with leucocytes, also a number of minute tubercles of epithelioid cells, but no giant cells. Not examined for tubercle bacilli.

"BLACK COW, No. 2.—Lung tissue: Result of examination identical with that of lung of White Cow, No. 3.

"Bronchial gland found in the piece of lung showed characteristic changes of tubercular inflammation, cheesy degeneration, tubercle tissue, and giant cells.

"Respectfully,

(Signed) "GEORGE A. TUTTLE, M.D.

"236 WEST FORTY-FOURTH STREET."

Large Families in North Carolina.—Dr. J. M. Hays, of Greensboro', N. C., writes: "*A propos* of a recent item in your columns in regard to the fecundity of women, I wish to state that in Granville County, N. C., there lives a mulatto woman, the wife of Daniel Boone, who is the mother of twenty-seven living children, several of whom have been my patients. This family belongs to a rather large class in that section popularly known as the 'issue free,' they and their ancestors for several generations having never been slaves."

METHOD OF TESTING FOR ALBUMINURIA.

By PHILIP JAISOHN, M.D.,

WASHINGTON, D. C.

THERE are innumerable methods for testing for albuminuria, but one must select the best process and use it constantly in order to be thoroughly familiar with the method, and derive practical benefit therefrom.

Among the common methods, the one most frequently used by the practitioners is: Boil the urine, then add a few drops of nitric acid to ascertain whether or not the urine is cloudy. But this method is too inaccurate to be of any service; and there is another method known as Heller's test, which consists in adding nitric acid carefully to the urine contained in a test-tube, and observing whether or not a band of cloudiness exists at the junction between the urine and the acid. This method is preferable to the former, yet there is a chance of making a mistake; because if there should be phosphates present in the urine, there will be a cloudy band, which, however, differs from the cloudy band caused by albumin; but it is sometimes very deceptive to the inexperienced eye.

I know another test, which is as follows: First acidulate the urine with acetic acid. (Filter it if turbid.) Fill the test-tube one third to one-half with the reagent composed of the following ingredients: Bichloride of mercury, 8 grains; tartaric acid, 4 grammes; distilled water, 200 c.c.; glycerine, 20 c.c.; and then add the urine, drop by drop. By this method one can detect albumin in the urine, when present in the proportion of 1 to 50,000. This is the most delicate test known; even more delicate than the trichloracetic-acid method, which is considered one of the most delicate.

But I have come to the conclusion that these two methods are of no practical use for clinical purposes, because by them one can detect albumin in the majority of cases, whether healthy or unhealthy. This is especially true of the bichloride of mercury test. I have examined twenty specimens of healthy urine and have found albumin in eighteen cases, by the mercurial reagent, which shows the worthlessness of the test. It is a well known fact that even healthy people pass a very small quantity of albumin during certain hours of the day; especially during digestion, and there is no pathological significance in this.

However, if one applies such a delicate test as the one I mentioned, the albumin will show plainly, and will cause unnecessary apprehension to the physician as well as to the patient.

There is one method I am in the habit of using, and which I consider the most reliable and practicable. It is more accurate than the method of boiling the urine and adding a few drops of nitric acid, and not so delicate as the trichloracetic acid, or the mercurial mixture.

Put a few drops of liquor potassii in a test-tube full of urine and filter it. Fill the test-tube one-half with the filtrate; then add fifteen to eighteen drops of fuming nitric acid. By this time the clear urine will be somewhat cloudy if it contains albumin. Boil it over an alcohol lamp or Bunsen flame, and let it stand for one half hour. There will be a sediment of whitish flakes or brownish granules. Boil it again and observe whether or not these will dissolve. If it is albumin they will not dissolve by the second boiling.

This is a fact of especial importance to medical examiners for insurance companies. It is their duty to guard against the admission of undesirable persons to the companies with which they are connected. But, at the same time, they must not apply too delicate a test in examining the applicant's urine; as, by applying such test, the albumin is apt to be found in most cases, resulting in the rejection of the applicant upon the ground that he has albuminuria. Of course such rejections by the medical examiner will be a loss to the company.

On the other hand, the medical examiner makes a grave mistake who applies such a crude and inaccurate method as boiling the urine, and adding a few drops of nitric acid, and then declares that there is no albumin; and the applicant is accepted, even though he may have albuminuria. The last-named test will not always bring out the albumin, unless there be a considerable amount in the urine.

Admitting applicants to the companies on the strength of such a test, in my opinion, is running a great risk. The method I prefer, and already described, is really the modification of so-called "heat and nitric acid test." If albumin shows by this test, it is a case for clinicians to watch the patient more carefully, and for the examiners of insurance companies to be justified in rejecting the applicant.

I may add here, that examination of urine should be required by the army, navy, and marine hospital service, in connection with physical examination of candidates for soldiers, officers, and sailors.

There is no other secretion or excretion in the human body which gives more information about the internal affairs of the constitution than urine, and it is therefore a subject deserving a careful study and investigation. It is hoped that in the near future all the practitioners in the land will realize the importance of this, and examine the urine of their patients whenever it is possible. It is true that most general practitioners have neither time nor facilities to do the chemical and microscopical examination of the discharges of their patients; but it is advisable for them to have this kind of work done by some one who has experience, skill, and time to do it. It is a justice to the patient as well as to the attending physician.

Correspondence.

THE DOCTOR'S WIFE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Your editorial on "Some Experiences of the Doctor's Wife," in last week's issue, strikes the key-note of your innate gallantry, which doubtless will cause many physicians' help (?) mates to induce, I almost said compel, their derelict husbands to subscribe to the MEDICAL RECORD.

At the risk of appearing less chivalrous than we would like the entire profession to be, I crave a little space anent your comments on the Brooklyn physician's wife who enriched the columns of the *Tribune* with her experiences.

Ab initio, the tone of discontent which characterizes the quotations you publish is all too prevalent among physicians' wives. They should rather be proud to have been selected by men who sacrifice themselves for the good of humanity.

Madam says, in connection with her life as a physician's spouse that "this is a big world and a hard world." Big in a sense it is, to those who have travelled much, *e.g.*, from the Bridge to the "L" terminus and back. But those who voyage from continent to continent, find distance annihilated and the world made very small by the people they meet, especially those who find nothing but cause for complaint in their destinies. The latter, like your fair writer, find it also a hard world. They forcibly suggest the woman who, on reaching heaven was welcomed by her optimistic husband with: "Well, at least you will say that this is a pleasant place!"

"To people of a certain taste, it may be," she sniffed, "but your professional engagements doubtless left you no time to select a dry cloud for me. I am consequently full of rheumatism, and this wretched halo neither sits straight on me nor has it any pretence to style. Had it been a fetid ulcer, or a broken bone, or some filthy disease on some immoral low wretch, you would have given it attention, but as to me——"

An anthem by the celestial choir drowned the remainder of her speech.

Madam objects to being "Mrs. Doctor." I once tried to meet this objection by saying that German women are very proud of the marital title "Frau Doctor;" the fair objector sneered that this was "too tonic" (pray remember it was *her* pun). But would your, or rather the *Tribune's* Brooklyn medical spouse rather be Mrs. Butcher, Mrs. Baker, or Mrs. Candlestick-maker? If so, why did she elect to become "Mrs. Doctor?" If she made so serious a mistake in her choice, why does she flaunt it before the world in a widely circulated medium? Why does she advertise that intellectual smallness which prevents her appreciating the exalted position she occupies?

She says that the certificate she obtained at the marital altar "has nothing to do with degrees." She is manifestly, then, one of that class which cannot be elevated by association with her husband. What if she has been asked to "set a broken arm or pull a tooth when the doctor (with a lower-case initial) was out?" Would there be anything degrading in having learned to apply a temporary dressing, or in cleansing the cavity and for the time being stuffing the tooth with cotton soaked in laudanum? Aside of thus holding the case for her husband—of course I refer to the broken arm—would it not be better if she gave attention to relieving human suffering, rather than to be moaning her lot and incidentally trying to besmirch the profession?

Madam objects to life in a house behind a brass sign. She correctly explains the cause with "when you stand in the window you are not a private woman in a private house." A woman who properly attends to her house and family has no time to stand in the window.

Madam complains that the physician's wife is not sure of her evening amusements, and finishes with a pathetic protest that she must "look after the family carving."

What hardships indeed! While her husband loses the very entertainments from which, by the way, his wife does not abstain, he is earning, by the hardest of hard work, the means for her to enjoy life and leisurely complain about it. And as to the family carving—a man who would allow his wife to carve while he goes off to save a life, is capable of any iniquity, even so vile a one as to neglect to button her shoes.

When one reaches the age that entitles reminiscences, one cannot but recall antitheses. I once had occasion to call on a successful practitioner, whose home life, because of its happiness, was the object of much comment. The doctor was not at home. His wife urged me to wait for the doctor, as she had sent for him a moment before I explained that I was not a patient, but a colleague. "I am so glad, Doctor," she responded, "won't you come in quickly, please. I have a man on the operating-table with, I think, his posterior tibial artery cut. I controlled the hemorrhage with an improvised tourniquet, but of course would not attempt to ligate."

I then observed that Mrs. Doctor (with a capital initial) had stained her elegant dress with blood. Her hat and gloves were on the floor of the operating-room; the patient was lying with his injured leg raised on an inverted chair, the trousers and drawers (I blush for the Brooklyn Madam at their mention) slit, and as neatly applied a tourniquet as I ever saw controlling the bleeding.

Just then her husband came in. She assisted him at the ligation; pride in her husband and in herself gleamed in her eyes and when all was done, she patted him affectionately on the cheek and said, "Good boy, darling."

"But, dearest," he said, "you have lost the matinée in consequence, and your new dress is ruined."

"What is a matinée or a dress to seeing a good operation performed by a good surgeon, and that surgeon *my* husband?"

That woman, whose name may not have been Harris, was proud to *possess* her husband; she sought happiness in being "the wife of Dr. Harris," and did not complain of the world not calling him "the husband of Mrs. Harris."

Is it a wonder that such a man succeeds? He leaves home with encouragement from her; he hurries home when tired, exhausted, and in doubt, to get more encouragement and stimulus for study and work from her; she is all and everything to him; both are happy, and she consequently does not fly into print to proclaim what a miserably wretched creature she is—probably because she fails to wreck her husband's career.

Are these lines too severe for Mrs. Brooklyn Doctor's Wife? Perhaps. But as she is one of very many who talk exactly as she writes, the reproof may not be *malapropos*.

Yet the morbidity she expresses is not her fault. In reality she should not be blamed. The real culprit is her husband—he should not have been such an idiot as to marry her, nor, having married her, so great an ass as to permit such sentiments to grow in her.

FERD. C. VALENTINE, M.D.

"THE WINCHESTER," 1242–1248 BROADWAY, NEW YORK.

"AS OTHERS SEE US."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Having read the leading article entitled "As Others See Us," in the MEDICAL RECORD for September 15, 1894, which article treats on Dr. Polaczek's book, "The Medical Science in the United States," I think it may interest your readers to learn what another German, Professor Dr. M. Schüller, of the University of Berlin, who has visited America, has said on Dr. Polaczek's publication. He writes in *Der ärztliche Praktiker*, No. 32, as follows:

"The book disappoints us in so far as it contains just the least of that which the title promises to give. The author confounds science with practical medical arrangements for instruction, with the modes of providing for the sick in public hospitals, with institutions of public hygiene, etc. A picture of medical science in the United States, on account of the part which the Americans have taken, and which is by no means a small one, in the progress of medical science, for instance in the field of anatomy, surgery, pharmacology, and especially operative gynecology, the reader of the book will look for in vain. What the author gives in his book are treatises on American hospitals, on therapeutic currents, on the caring for the insane, on the American physician, on American universities, on the sanitary and hygienic conditions of the large cities. We find everywhere the intention to give the German reader a true picture, to do justice. According to our judgment the author has but succeeded in the chapters on the Insane, on Quarantine, on Sanitary and Hygienic Conditions of the Large Cities, on the American Physician. The chapters on the American Hospitals and the American Universities are, it is true, quite correct in what they give, but they do not by far exhaust the subject treated. In regard to the hospitals, we notice in America, as it is quite natural in such a large continent with different distant States and cities, and therefore different climates, considerable variety in regard to architectural plans and inner organization. Besides, some of the arrangements which differ from those in Germany are not specific American, but originally English. Especially incomplete, however, appears the superficially written chapter on American Universities. We cannot overlook some of those easily recognizable drawbacks of the specific American University education, but we should not overlook, either, the fact that just at present mighty exertions are made in almost every State to remedy the existing evils, and to make the medical instruction more profound."

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 22, 1894.

	Cases.	Deaths.
Tuberculosis	68	84
Typhoid fever	27	7
Scarlet fever	38	5
Cerebro-spinal meningitis	0	0
Measles	24	5
Diphtheria	107	25
Small-pox	5	3

The Anti-tetanic Serum and How to Use it.—In the treatment of tetanus an anti-tetanic serum, obtained from the horse and prepared in the dry state and sent out in tubes each containing four to five grammes, is a little more than the minimum dose considered curative in the case of a man. The substance is to be dissolved in distilled water, and injected subcutaneously. The dose must vary according to the gravity of the symptoms, and requires to be repeated in smaller quantity for several days. In regard to the cases hitherto reported, doubt has been expressed by some as to the severity of the attack, it being well recognized that the less acute forms of tetanus by no means partake of the gravity which attaches to those of more acute onset. These doubts are, however, in some cases ill-founded, and now that the material for the treatment can be stored and kept at hand we ought quickly to accumulate sufficient evidence to decide on its utility in surgical practice.—*British Medical Journal.*

Anarchists, Anti-vaccinators, and Anti-Pasteurists.—Anarchists, anti-vaccinators, and anti Pasteurists appear to be foregathering just now in a friendly and instructive fashion. The anarchists have been assembling at a friendly meeting at the house of the president of the Anti-vivisection League in Paris, and a little outdoor gathering, including a quaint collection of "Anti's" generally, to protest against the British Institute of Preventive Medicine has had its little innings and is reported in all the papers. It is just as well that these wild people should have their silly say unanswered and without comment. But it is rather painfully comical to find a minister and a man of Mr. G. W. Russell's culture writing to them to announce that he detests Pasteurism—and of course also Listerism. Why not add that he has a contempt for the equator and grave doubts about gravitation? It reads oddly at this moment when the whole world has been meeting to do honor at every quarter of the globe to its two greatest benefactors—Pasteur and Lister, and on the day after Lord Salisbury's eulogy *urbi et orbi* of the Listerian conquests as among the few great positive victories of modern science on which he could definitely congratulate mankind. But oddity is the badge of the anti-party, who delight in posing as "against all science" and "agin all government," and appear to think that there is something progressive, emancipated, and metaphysical in this attitude. To be logical, Mr. Russell should add the inevitable converse of his proposition, and declare that he loves small-pox, is much attached to hydrophobia, and adores blood-poisoning and high hospital mortality. This would put him quite in sympathy with his friends, the orators in the cart to whom he addressed this interesting missive.—*British Medical Journal.*

A Monument to Semmelweiss.—During the session of the Congress of Hygiene and Demography at Budapest, a monument was unveiled to Semmelweiss, the precursor of Lister. As long ago as 1847 he urged the necessity of washing of their hands in an antiseptic solution by surgeons prior to undertaking an operation.

The Sterilization of Bread.—At the meeting of the British Medical Association, on August 3d, the investigations of Mr. Walsh, of London, and Dr. Waldo, of Southwark, as to whether baking sterilizes a loaf of bread, were the subject of an interesting discussion. Mr. Walsh read a paper based on a large series of experiments. Its main conclusion was that baking does not necessarily destroy the vitality of micro organisms contained in dough. With regard to temperature, they had found that the average maximum temperature in the centre of a large loaf varies from 163.4° to 186° F., and in a small loaf from 186.8° to 203° F. As the heat increases steadily in the centre of a loaf, any organisms present are exposed for a short time only to the maximum temperature reached. The average micro organism will withstand a prolonged exposure to a much higher temperature without being destroyed. Spores are much more resistant again, so that on theoretical grounds alone, having ascertained the maximum temperatures in the centre of the loaf during baking to be those mentioned, they might venture to predict that organisms (or their spores) would not be destroyed by the process of baking. By the method of plate cultivations they succeeded in obtaining thirteen different species of micro-organisms from the centre of recently baked (a few hours after baking) loaves. The latter were obtained from bakeries in different parts of London, rich and poor. Numerous experiments were carried out for them by Mr. Walter Severn on sixty-two loaves. It was clearly shown, if the results were trustworthy, that certain non-pathogenic organisms are able to survive the process of baking.

Some Curious Life Insurance Details.—According to the *Medical Press* it appears that in Germany a man who loses both his hands in an accident can claim the whole of his life insurance money, if he be insured, on the grounds that he has lost the means of maintaining himself. The loss of the right hand reduces the claim to from seventy to eighty per cent. of the total; that of the left to from sixty to seventy per cent.; the thumb is valued at from twenty to thirty per cent.; the right index finger at from fourteen to eighteen per cent.; and so the reduction continues until the little finger is reached, when the percentage is put down at from nine to twelve. No figures are given as to the value of the various segments of the lower extremities.

Cramps in the Legs in Diabetes.—Unschuld calls attention to an early symptom of diabetes, which is seldom mentioned by writers on the subject but which is yet frequently found, and may assist in an early diagnosis of the affection. This symptom consists in cramps in the calves of the legs, and is found in about twenty-six per cent. of all cases. The pains occur with especial frequence in the morning upon waking, and occasionally also during the night, when they are usually accompanied by a desire to urinate. They are rarely troublesome in the daytime, unless after a nap or a bath. Cramps of this nature, occurring in a person in feeble health, should always, Unschuld holds, suggest the necessity of an examination for sugar.

The Confidential Relations of the Physician.—A correspondent, "Medicus," writes: "Your view of the decision of Judge Cole in your editorial of September 1st, is doubtless that of the majority of the medical and legal professions, but the learned jurist's action must be based upon the ruling of the Attorney-General of the United States and Supreme Court, since the Naval Regulations require medical journals (containing as they must do, a record of personal and family secrets 'patient's confidences' and 'privileged communications' necessary for diagnosis and for pension claims) to be 'subject at any time to the inspection of the captain and fleet surgeon.' This violation of the spirit of the Hippocratic oath is not required in the army nor in the Marine Hospital Service."

THE TREATMENT OF DIPHTHERIA, WITH SPECIAL REFERENCE TO THE EFFICACY OF ANTITOXIN.

By ADOLF BAGINSKY, M.D.,

A. O. PROFESSOR OF PEDIATRICS, UNIVERSITY OF BERLIN.

In 1891 I published, in the "Archiv für Kinderheilkunde," a paper on "The Therapeutics of Diphtheria from the Kaiser and Kaiserin Friedrich Children's Hospital," in which I stated that certain requirements of the remedy should be formulated: 1. The remedy should be capable of destroying the diphtheria bacillus at the seat of infection without injuring the surrounding tissues or the body. 2. The remedy should prevent the formation of pseudo-membranes, which latter might cause laryngeal stenosis and asphyxia. 3. The remedy should prevent and neutralize the products of the bacilli in the blood and lymphatic circulation, possibly also the septic material in the nerves.

The therapeutic measures consisted in applying local treatment to the pharynx, and strengthening nourishment, with cardiac tonics. Other remedial agents, when the diphtheritic process extended to the larynx, threatening laryngeal stenosis, were tracheotomy and intubation.

The local remedies used were those which had both a solvent and an antiseptic effect, namely: Acid. salicylic., 1–2 to 1,000 for gargling and irrigation with the syringe; acid. boricum, 3 per cent.; kali hypermanganic, 3 per cent; iodid. chlorid., 1 to 2,000; auro-natrio-chlorat., 1 per cent., for swabbing. Acidum lacticum, 10 per cent., for swabbing; 2 per cent. for spraying. Acidum carbolicum, alcoholic solution of 5 per cent., for swabbing; 2 per cent. to 3 per cent. for gargling. $HgCl_2$, 1 to 3,000, for gargling; 1 to 500 for swabbing. Oleum citri for spraying; acid. acetic., 2 per cent. to 3 per cent., for gargling, and 5 per cent. for swabbing. Ol. terebinth. for inhalation. Ichthyol, 2½ per cent., sublimat., 1 per cent., watery solution.

Iod-phenyl mercurial preparation by a chemist (Goldmann) is at present being tried. Ferric chloride is applied as an ointment with pledgets of cotton, and mechanical friction avoided.

Of all remedies mentioned thus far, those containing bichloride, and after the latter the 3 per cent. (alcoholic) carbolic solution proved most efficient. Boric acid, salicylic acid, iod trichlorid., and auro natrio chloratum were absolutely inefficient and useless. Acetic acid proved useless. The kali hypermangan. proved beneficial against the fetor, but negative in diphtheria. The ol. citric. and ol. terebinth. were decidedly inefficient; the latter was used in a steam spray. I am decidedly opposed to the application of local caustic treatment, having always had deleterious results from it. Besides solvent remedies like lactic acid, and aq. calcis, 5 per cent. to 10 per cent., solutions of papayotin were used, and were applied with cotton swabs; this did not, however, prevent the extension of the process to the larynx. Besides the local remedies mentioned, an ice-bag externally and cracked ice internally were used, until the inflammatory infiltration of the pharyngeal mucous membrane had disappeared. Subacute and chronic swellings, rather late hyperæmias in the pharynx, were treated with a tannin solution, 1 to 80, with twenty parts of glycerine added.

In two cases treated with submucous injections of 3 per cent. carbolic solution (Heubner), injected in the vicinity of the infiltrated tonsil, they were decidedly useless, and showed at post-mortem hemorrhages at the seat of the injection. Among internal remedies sherry, port wine, champagne, and Greek Alicante wine were used. Cognac, subcutaneous injections of camphor in oil, and 10 per cent. alcoholic solution were also employed. In mild cases 1 to 2 per cent. kali chloric. was used, but was always discontinued, fearing nephritic complications. The same was true of ol. terebinth., which most children vomited. Decoct. china, 10 to 100, and added to this, aq. chlori. ten parts; tinct. ferri chlorati æth.; tinct. ferri pomati; and papayotin wine were used internally. Inhalations of oxygen did at times redden the lips and mucous membrane of very sick children, but did not have any curative action.

To counteract the deleterious effects of heart failure subcutaneous injections of strychnine, camphor, and caffeine were used. I have recently discarded entirely the use of strychnine. The complications—pneumonia, pleuritis, nephritis—were treated in the regular way. Antipyretics must be very cautiously used in all complications following diphtheria; even cold packs must be cautiously administered. Of 244 cases 125 were cured, 9 were transferred, 9 refused to be treated, 5 were convalescing, 95 died. The mortality was 40.04 per cent. Thirty-seven of these cases were of the severe gangrenous septic diphtheria, and all died. Deducting the latter, and including a great number in which tracheotomy was performed, there remains a mortality of 23.01 per cent.

Since the time of the German and French authors, more especially of the Koch school, things have changed considerably. Behring is credited with giving us a new remedy for diphtheria. In an elaborate book published by Behring he details the subject, and treats of it exhaustively. Behring uses the blood-serum of animals immune against diphtheria as a specific remedy for the treatment of diphtheria, or for the prophylaxis of cases having been exposed to diphtheritic infection. Associated with Behring have been Ehrlich, Wassermann, and Wernicke, besides a great many others. Hans Aronson has followed the directions of Behring, and has made a serum which appears to be equally as good, if not better, than that made by the former gentleman.

In the Kaiser and Kaiserin Friedrich Hospital in Berlin we have used an antitoxin which was generously given to us by Aronson. The results obtained by the use of antitoxin have been reported by one of my assistant physicians, Dr. Katz. From March 14th until July 25th, 163 cases of diphtheria were treated, including numerous malignant cases. Of this number only 23 died, so that the mortality was 14.37 per cent. This excellent percentage has never yet been equalled with our best form of treatment even in the mildest epidemics. Among the fatal cases there were several tuberculous children, and several whose genuine diphtheria was complicated with scarlet fever, so that the mortality of uncomplicated cases of diphtheria will be much less. It is difficult to say if a nephritis would have appeared as well without as with the injections. The course of nephritis in the cases treated with antitoxin were exactly the same as otherwise. Severe cases of nephritis following injections were never noticed; whereas several cases

with severe albuminuria had wonderful improvement following the use of antitoxin injections. The heart did not show any difference in rhythm, or in the heart-sounds, or in the character of the pulse. On the fourth day following an injection a small abscess appeared in one case, which was treated by incision, and rapidly healed. Child discharged cured.

Several cases showed exanthema following an injection, especially on the extremities and in the region of the knee-joint. No elevation of temperature accompanied the exanthema, nor was there pain. They appeared like scarlet fever, but in small, confluent places, with no temperature and rapid disappearance, proving them to be simple exanthemata.

Other cases looked like measles. There was, however, no desquamation noticeable. There were four typical cases of urticaria of the whole body. Katz noticed in a four-year old child a distinct capillary pulse when the nettle-rash appeared. Constitutional symptoms were never noticed, and erysipelas never occurred. The membranes in the pharynx behaved variously. In some they appeared to spread, while in others they seemed to disappear. Not one single case had laryngeal diphtheria nor stenosis after the injection. Those cases with laryngeal stenosis and croupy cough were admitted with these symptoms, and all were treated either by tracheotomy or intubation soon after their admission. In one case, a child with excessive dyspnœa (laryngeal) was tracheotomized, and recovered. The glands did not seem to be influenced by this treatment. There was no specific action noticeable which could be attributed to this remedy. Some cases appeared very bright; this might have been the case otherwise.

The temperature showed nothing of interest In two children there was a sudden rise followed by a sinking to normal. In most cases the temperature sank after the injection. If the pulse was bad, the heart-sounds weak, and the rhythm irregular, the remedy did not seem to influence the same. At times, absence of patellar reflexes, processes of accommodation, rhythm of the heart, paralysis of the musculi aducentes, paresis of the respiratory muscles frequently appeared. Death took place in the same manner as in ordinary cases. Among the cases mentioned several died of pneumonia, paralysis of the heart, and septicæmia. Those that died of croup were so far gone that we did not expect to save them; still, tracheotomy was performed, and large membranes pulled out of the bronchial tubes. Of the septic cases three were admitted moribund, and a fourth case was in a typical state of septic diphtheritis. Pneumonia cases that died were of the severest kind. Improvement appeared so frequently during its course that at times there was good hope. In those children (brothers and sisters) where at times the disease was treated within the first few days, the mortality was less than 10 per cent. In former times the mortality among children where tracheotomy was performed was much greater; whereas formerly from 22 per cent. to 24 per cent. were cured, since using the antitoxin on severest cases 34.30 per cent. were cured. It was difficult to ascertain the cause of the disease. Twenty-five cases which had been exposed to diphtheria were carefully examined a number of days, and all developed diphtheria. As they were examined daily, they were attended when the first symptom appeared. Not one of these developed nephritis nor cardiac trouble. Their sisters and brothers, who had been previously admitted to the hospital, some as severe cases, died. All twenty-five cases were discharged cured.

Dr. Aronson gave us a mild solution of his remedy, which was used in seventy two cases for immunity. Of all these cases but eight took sick very mildly and recovered easily. We learned that much larger doses were necessary to produce immunity in children. Not one case relapsed nor showed a single symptom. It will therefore appear that we have been using a remedy which deserves further trial. If, therefore, the remedy will give even more beneficial results than heretofore, then we have in the blood serum therapeutics inaugurated by Behring one of the greatest triumphs in the annals of medicine.

DIPHTHERIA ANTITOXIN OR HEALING SERUM IN THE TREATMENT OF DIPHTHERIA.

By LOUIS FISCHER, M.D.,

NEW YORK.

INSTRUCTOR IN DISEASES OF CHILDREN AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; PHYSICIAN TO THE CHILDREN'S DEPARTMENT OF GERMAN POLYCLINIK, PHYSICIAN TO THE MESSIAH HOME FOR CHILDREN, ETC.

WHILE in Berlin a month ago, Professor Baginsky gave me every possible opportunity for acquainting myself with the new antitoxin treatment for diphtheria. The clinical experience seen abroad is my reason for detailing the method for use in both hospital and private practice

It will be proper to state that at present two kinds of "serum" are being used. They vary only in strength and are made by rival firms.

The one firm sells it under the name of "Behring-Ehrlich Heilserum," the other is "Aronson Heilserum."

As I saw but a limited number of cases of diphtheria at the Institut für Infektions Krankheiten (Koch), by courtesy of Dr. Wassermann, I will confine myself more particularly to the consideration of Aronson's serum, with which my experience is more extended.

This serum is a clear, colorless liquid of thick consistence, quite sticky, and has a slight carbolic odor. In order to preserve it, it is mixed with 0.2 per cent. trikresol, as some of the organic material might otherwise decompose.

Two objects are sought for in using antitoxin: 1. Immunity during an epidemic, or where a person has been exposed to diphtheria. 2. Healing after the disease exists.

In giving antitoxin it has been customary not to neglect the other usual forms of treatment, and it will be interesting, I hope, to detail a typical case.

The place for injecting the antitoxin is behind and between the shoulder blades and also the connective-tissue of the arm and the thigh. Gentle massage at a slight distance from the point of injection is done to diffuse the injection; but this is not absolutely necessary.

Of almost two hundred cases treated in the Kaiser and Kaiserin Friedrich Hospital but one abscess appeared, which was incised and healed promptly. No reaction followed injections.

It will be remembered that when Koch's tuberculin was injected, fever, chills, diaphoresis, etc., were noticed, which made a typical and distinct reaction as the result of the injection. These phenomena were evidently the natural consequences of a septic material thrown into the circulation, as was demonstrated by Dr. Shrady and others who used the lymph in New York.

When antitoxin is injected, however, there is no reaction. The quantity used varies according to the severity of the symptoms, the gravity of the epidemic, and the age and vitality of the patient. In some cases one injection suffices, whereas in others a second injection on the succeeding day may be required. The usual dose is 5 to 10 c.c., hypodermically. At times 20 c.c. is administered when a very rare epidemic exists.

The instrument used is an ordinary hypodermic syringe with asbestos fitting, which can be sterilized in a Bunsen burner, or the Koch's syringe is used in some hospitals abroad.

Exanthemata, the rash of scarlatina or measles, resembling typical urticaria, sometimes appeared following injections, but without an evolution of temperature. These eruptions last several days and then disappear without special treatment.

Malignant cases of diphtheria are greatly improved and frequently recovered; quite frequently even cases with laryngeal stenosis recover rapidly, and in which tracheotomy was even performed.

Professor Baginsky, who has prepared a special paper

for the MEDICAL RECORD, will give a detailed account of the use of antitoxin, by Dr. Katz, under his directions. All of his assistant physicians, notably Dr. Lewin, in the diphtheria pavilion, gave me detailed accounts of their cases, which are virtually the same as Professor Baginsky has reported. Complications were rarely noticed, and symptoms of cardiac weakness directly attributable to the antitoxin were not observed.

The immunity conveyed by an injection of antitoxin lasts about three or four months, after which it will be wise to repeat the injection.

Dr. Hans Aronson told me that the serum made by Schering's factory is much stronger than Behring's, and expressed it by saying that his serum of 400 Einheiten was equivalent to 800 of some specimens obtained by him.

It is the aim of Aronson to produce a serum much more concentrated than the one in use at present, for he informed me that 5 gm. of the present serum was as strong as one litre or 500 gm. of what was previously made in the beginning of the manufacture of this remedy.

The following case is the first one in which I have had occasion to use antitoxin in private practice.

Dora T——, aged eleven, a healthy, well-nourished girl, had been ill about one day. On the same floor of this tenement-house, in an adjoining room, a boy, aged fifteen, was sick with diphtheria, being attended by Dr. Schmid. My patient was exposed, and her cautious mother examined her throat and discovered some patches. When I first saw her I found the temperature in the axilla 102⅗° F. There was intense thirst, general pains in the body, marked malaise, dysphagia, and a headache. Pseudo-membranes covered both right and left tonsils and the posterior pharyngeal wall. I ordered a placebo, and returned with Dr. Gerlach, at present a physician at the New York Post-Graduate Medical School.

I first made a culture from the throat, the report proved Klebs Loeffler bacilli, verifying the clinical diagnosis. I then injected 5 c.c. of serum with a small hypodermic syringe, at which injection quite some serum was wasted. I then took a better syringe, and having sterilized the point in an alcohol lamp, injected 5 c.c. of Aronson's serum in the back by pinching a fold of skin between the shoulder-blades. No reaction followed. The next day my little patient was greatly improved in both subjective and objective symptoms. Greenish-yellow pseudo membranes remained about two days following the injection, and on the third day no trace of membranes were visible, although the pharynx and tonsils were still inflamed. On the fourth day no sign of the disease remained, and the little girl was up and seemed to be quite hungry. The general malaise seemed to pass off about one day after the injection. This is near the sixth day and the membranes have entirely disappeared. The child eats and sleeps well and is apparently in perfect health.

This little patient was attacked much more severely than the first child that infected her. My patient eats and sleeps well, and is apparently very bright. A careful examination of the urine was made. Albumin sparingly and an excess of phosphates were present. The trace of albumin also disappeared. No reaction followed the injection of antitoxin.

In the same family one other child has received 2 c.c. of serum as a prophylactic. I am anxious to see if she will be infected or remain immune.

In some severe cases much larger doses may and should be used, for Aronson told me in Berlin that he frequently injected 50 c.c. at one injection, and this may even be repeated on the following day, although the usual dose injected was 10 c c.

This will convey a general idea of how this remedy may be employed, and if we can rely on statistics, then we have in antitoxin not only a positive remedy in diphtheria, but the beginning of a new form of treatment which will eventually save the lives of thousands of patients.

187 SECOND AVENUE.

SURGICAL PROBLEMS IN INTRA-PELVIC AND ABDOMINAL DISEASES.

BY A. H. CORDIER, M.D.,

KANSAS CITY, MO.

SOME time ago, while doing special work in a large Eastern city, I had many opportunities to see the work of the various operators, and it was a noticeable fact that, while one operator would have a mixture of the worst neglected and complicated cases imaginable, including old adherent and caseous Fallopian tubes and ovaries in emaciated and septic patients, another operator's cases would be confined to the removal of cystomas and plastic vaginal and cervical cases. This led me to inquire of one of the operators why he did not have so many "pus cases" as some of his confrères. He replied that he believed that "the woods are not full of them," as some would have us believe. A few days later I visited this same gentleman's clinic, which is a large one, and in two hours I found six pairs of old, sequestrated Fallopian tubes full of pus, carried around by six of the most careworn and miserable-looking women imaginable. They had their vaults frescoed with Churchill, and were directed to return for another decoration the following week.

Conservatism is a grand principle, but unfortunately, in the hands of skilful men the application of this rule is only too frequently responsible for destructive or complicative delays, if I may use such a term. Conservatism is a prophylactic if early and intelligently carried out or applied. It is equally injurious, if used with this same idea in view, in cases where time and experience have demonstrated its futility.

Occasionally an article appears in some of the many valuable medical journals of our country entitled "A Plea for Conservatism," or the like. That these articles are well worded by conscientious practitioners in most instances no one will doubt, and to one unaccustomed to seeing the true pathology from a practical stand point, they carry with them weighty evidence that, with rare exceptions, all surgical procedures for the relief or cure of the same, are unnecessary and unwarrantable. But to him who has handled these cases surgically, and understands their progress, the position of the so called conservative is not well taken. Many are attempting to do this class of surgery (pelvic) who have not the anatomical or pathological knowledge or practical experience to enable them to make a diagnosis between an operable or non-operable case. To this class sermons on qualifications and attainments should take the precedence of lectures on operative conservatism.

Good missionary work is being done in this field by educating the general practitioner and the specialist that they should go hand in hand in their work. By friendly discussions and exchange of views on topics of vital import to both, the patients reap the benefit of the combined council.

We have men of renown in this country as operators and authors, whose utterances along the line of so-called conservatism are producing much mischief and causing many deaths by the adoption of these false doctrines by lesser lights. After seeing much of the work of some of these men I am surprised to see some of their ideas in print so foreign to the practice actually pursued by them in their work. One is almost tempted to doubt the sincerity of some of their utterances.

We should advise against the removal of sound organs, but at the same time endeavor to impress upon our associates the necessity for early surgical work where experience with like cases has demonstrated the futility of any other course.

Operations for the removal of diseased appendages are not followed by the same amount of reflex disturbance as are those cases where sound organs are removed to cure (?) a globus hystericus, or the like—an unwarrantable procedure. Most women with suppurating diseased tubes and ovaries are unsexed by the pathology, and I

have had women with these diseases at an age too early for a normal menopause to present all the climacteric phenomena. In many cases it is not a question of "Will this woman have an exaggeration of the menopause phenomena if we operate?" so much as "Will she be free from pain after the operation, and can she recover without the aid of surgery?" These questions have been answered many times, both by non interference in the cases, with failures, and by demonstrations at the operating-table—the successes. Women whose appendages are diseased to such an extent as to require removal are sick women, and are necessarily in that low vital state that where there is an inherent tendency to insanity or neurasthenia the surgical procedure for the removal of the diseased structures may precipitate the mental phenomena to an exaggerated and disagreeable degree.

If we are not to remove life-endangering and comfort-breaking pathological processes when found, pray tell us what are we to do? Fold our hands and let nature (pathology) take its course? Or do worse, visit these cases with poultices, Churchill, and hypodermics? We can illy afford, as true surgeons, to cater to the plea that the poor sufferer will be robbed of her womanly traits; that she will be despondent, lose her sexual desires, suffer from flushes and flatulence, and that her husband (too often responsible for the wife's sufferings) will become dissatisfied with the post operative condition of his wife. I have never seen a woman suffering with diseased appendages where the disease was of sufficient severity to require removal of the organs, who was not a sexually useless and despondent wife, and a sick woman as well. Sound organs should not be removed. Any condition that may be induced by the surgical procedure may likewise be induced by the continuance of the disease requiring the surgery.

I believe the sexual system is located elsewhere than in the tubes and ovaries. The nymphomaniac manifests not only an increased sexual desire, but a loss of self-control, often with hallucinations and delusions, the whole cycle having its origin in the cerebrum.

Radicalism is a dangerous expression to use; equally harmful is the term conservatism applied to a disease the tendency of which is to destroy function, make life miserable, or produce death if too long a delay of a proper procedure for its cure is permitted.

Many cases early in the history of the malady are permanently cured by intelligent and skilled surgery. The same case, if allowed to run an uninterrupted course for any length of time, may assume proportions or characters of some magnitude or danger that to attempt to relieve the same would not only be fraught with danger from the operation, but the crippled surrounding organs would preclude the possibility of a complete restoration to health.

These are cases that bring disappointment to the patients and friends, as well as to the sanguine physician and surgeon, run up the mortality, and give surgery a bad name.

It is the early removal of diseased structures, the history of which is to continue a downward course, that gives us a *nil* mortality, the patient renewed health, and the family physician increased confidence in the justifiability of the operative procedure.

Early operations are not only curative measures, but prophylactic methods as well. It is not only the diseased and worse than useless organs and structures the true abdominal surgeon is removing, but he is liberating sound imprisoned organs, the function of which is essential to life. This is not only life-saving work, but a comfort-giving procedure. No true surgeon is clamoring for a thousand or ten thousand laparotomies, but is ever pleading for timely needed work—is ever pleading for the recognition of the necessity for quick surgery in cases where surgery, at some time in the history of the malady, becomes necessary.

No one at this time would think of advising a woman to wait until the growth was so large or her physical condition such that she could not walk a mile, before having the tumor removed, as was done a few years ago, by a great writer. This would be dangerous conservatism.

It is as absurd to call the removal of a sequestrated Fallopian tube and ovary a mutilation, as it is to call an amputation of a hopelessly injured leg a mutilation. These operations are performed to fulfil strictly surgical indications—saving life and relieving suffering. It is a daily occurrence to see reported that a case diagnosed as appendicitis has recovered. That this is true no one will doubt. Many cases reported as recovered have since died from recurrence of the disease, and many an appendix, supposed by the medical attendant to be dangling healthfully in the peritoneum of his patient, is saturated with Müller's fluid or alcohol, in a specimen jar, while the patient has long since died from a perforation, or has been saved by good, timely surgery. No operation in surgery has a higher mortality than that of the delayed operations for the removal of a diseased vermiform appendix, but if done early the procedure has an almost *nil* mortality. A late writer reports twelve cases treated on the expectant plan with two deaths (sixteen per cent. mortality), and two cases with recurrent attacks (sixteen per cent. of recurrences). The writer says of the two who died that they were almost in *articulo mortis* when first seen by him. He does not tell us whether he put on a fresh poultice and hid from view the big abscess bulging in the right iliac fossa, or gave the patient an extra dose of opium to relieve the pain of the sufferer and obtund the senses of the doctor. These cases should have been seen by a good surgeon who would have stopped all opiates and let out the pus, applying the same surgical principles to this locality as to other parts of the body: "When you find pus, let it out." Appendicitis is a surgical disease, and the surgeon should see the case with the physician as soon as the diagnosis of appendicitis is made. Let the physician and the surgeon watch the case together.

The modern application of the principles of surgery as applied to diseased Fallopian tubes is the same that has been practised for ages as applied to the surface of the body. A felon is lanced, the earlier the better. The good surgeon does not advise delay, and while waiting paint the finger with Churchill or apply hot irrigation. As soon as evidences are present that pus is forming he lets it out.

How thankful the abdominal surgeon would be could he lift up a pus-filled Fallopian tube without entering the peritoneum, "rip it up the back" (as suggested by a late writer), scrape it out, destroy all the remaining epithelium, and by redressing it restore its calibre so that the spermatozoa may throng its canal and pregnancy take place, just as though this culture tube had not been a hot-bed for gonococci and other pathogenic bacteria for months previous.

All cases of salpingitis are not operable cases, but the majority of cases seen by the specialist are old purulent cases with tubes filled with pus and caseous *débris* strictured in one or more places, uterine and abdominal ostia closed. Here it is conservatism to remove these dangerous sequestra.

Hardly a week passes without seeing one or more cases of far advanced cancer of the cervix uteri extending into the broad ligaments, bladder, or rectum. These are inoperable cases when so far advanced. Again I see cases where a diagnosis of a cauliflower growth has been made, which proves to be a badly lacerated cervix, with the resulting local mischief attending an unhealed tear in this locality. Surgical diseases should be attended by the surgeon in conjunction with the regular medical attendant. The time to operate, if necessary at all, could then be arrived at mutually and timely.

When the masses are educated in every sense, when gonorrhœa is stamped from the face of the globe, when the perniciousness of criminally induced abortions

and the dangers of the indiscriminate use of the sound are understood, then there will be less necessity for the practitioner to hurl at the specialist his "bucket or barrel of ovaries;" then the specialist will cease his cry against needless tinkering and dangerous procrastination; then our women will have their babies at full term, in the good old way. Until this goal is reached, the use of the knife will be found necessary in properly selected cases to relieve the suffering and save the lives of these unfortunate women with diseases, the result of the above-mentioned causes.

A STUDY OF THE MEDICAL ASPECT OF FOUR RECENT CASES OF ACUTE APPENDICITIS.[1]

By JOHN L. HEFFRON, M.D.,

PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE, COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY.

MR. PRESIDENT, AND MEMBERS OF THE ONONDAGA COUNTY MEDICAL SOCIETY: As a preliminary to the study of the salient features in the four recent cases of appendicitis which it is proposed to discuss to-day, it will be necessary to give, briefly, the history of each case, from its inception to the time when surgical treatment was resorted to.

CASE I.—Mr. G. K——, aged thirty-nine, a German, of sturdy build, weighing about two hundred pounds. He worked all day July 25, 1893, at his trade, stone-cutter, doing heavy work. He had a diarrhœa, attributed to indiscreet eating, of which he made no complaint until he returned from his work in the evening. His diarrhœa continued during the night, with occasional vomiting and colicky pains.

In the morning, not being relieved, he sent for me. I found the patient in bed, and an examination showed, in addition to the above symptoms, that the pain, which had at first been indefinite in location, had become limited to the right iliac region, though it radiated, in paroxysms, from this point upward and inward toward the umbilicus, but was never intense.

Palpation revealed slight tenderness, most marked over McBurney's point, but also extending to a considerable area in every direction.

Percussion indicated an area of diminished resonance in the right iliac fossa.

His pulse was 70, of fair strength and volume, and his temperature was normal. A tentative diagnosis of appendicitis was made, and he was given an opiate and salol.

At the evening visit it was found that he had had a severe chill, lasting several minutes, which was followed by an increase in the pulse-rate and fever, with sweating. At this visit his pulse was 90, and his temperature was 100° F. He had vomited twice during the day; his bowels had moved several times, and the pain was more intense, though not constant, and the tenderness was increased. There was some tympanitis, so a saline was added to the treatment. The family were apprised of the serious nature of the disease, and were told if no decided improvement was manifested by morning, surgical measures must be resorted to.

July 27th.—Patient was seen about 10.30 A.M. He had passed a fairly comfortable night; his bowels had moved early in the morning, the stool being a watery discharge of very foul odor, but containing scarcely any fecal matter. His pulse was 100, and of diminished strength and volume; his temperature was 102° F. There was a little increase in tympanites, the abdomen being quite soft, but the pain was more marked, and the tenderness was much greater, and most exquisite over McBurney's point.

The opiate treatment was continued, and the family notified that I would bring a surgeon at the earliest possible moment in the afternoon.

At 4.30 P.M. Dr. Jacobson saw the case with me. At this time the temperature had fallen to 101° F., but the pulse had increased to 116, and was irritable. The local symptoms were aggravated, both pain and tenderness having increased since morning, and the abdomen was somewhat distended. It was agreed that the only hope was in an immediate operation, which was at once acceded to, and prepared for, and accomplished by six o'clock—forty-eight hours from the time he had complained of any abdominal trouble, and thirty hours after there had been any elevation of temperature or increase of pulse rate.

A general septic peritonitis and a gangrenous appendix were disclosed, the details of which will be given by the operator. Death followed about twenty hours after this operation.

CASE II.—R. H. L——, fifteen years of age, a student in Colgate Academy, Hamilton, N. Y., having a good family history and no previous abdominal trouble. He, with his society fellows, participated in a "peanut bum," on Saturday night, March 17, 1894, consuming peanuts, bananas, and soda-water, as only a fifteen-year old boy can. All went merry until Tuesday night, March 20th, when he was attacked with severe diarrhœa and vomiting, keeping him busy all the early hours of March 21st. On that day a physician was called, and placed him under treatment, evidently wavering in his diagnosis between a possible typhoid fever, which was endemic in the neighborhood of his boarding-house, and appendicitis. His temperature was 101° F., and his pulse correspondingly rapid; he had considerable pain and tenderness in the right iliac region, which was somewhat masked by a strain of the abdominal muscles, received in practice on the base-ball field. He was up and around during the day, however, and partook of the usual supper served to healthy boys.

March 22d.—The pain was considerably diminished, as well as the tenderness, and the diarrhœa and vomiting had ceased, but his temperature and pulse remained slightly above the normal.

March 23d.—He was in about the same condition, and was advised by his physicians to return home. Information was sent me that he was probably coming down with typhoid fever, a fear which was quite reasonable. At 11 P.M. he came into my office, having walked from the Central Depot with his father, who had met him at the train. After securing the above history an examination was made: The pulse was 100; temperature, $101\frac{5}{10}$° F. Complained very little of either pain or tenderness; abdomen flat and soft; palpation disclosed a point of considerable tenderness at McBurney's point, and a tumor was distinctly made out in this location, about the size and shape of a butternut. There was dulness over the descending colon, as well as over the tumor. Thinking there were more peanuts—though being positive in a diagnosis of appendicitis—a mercurial was prescribed. As the patient was suffering from acute bronchial catarrh, a sedative was also given.

March 24th.—Patient had a good night. Pulse, 100; temperature, 100° F.; had three movements of the bowels; is very hungry, but is allowed no solid food. Local symptoms unchanged. A daily improvement in every symptom was recorded until

March 28th.—At this visit his pulse was 92; temperature, 102° F. No complaint of abdominal symptoms from patient, but examination reveals an increased area of dulness, not particularly tender, and tumefaction in right iliac fossa evident to the eye; abdomen elsewhere flat and not tympanitic; bowels have not moved in two days. Closer questioning gives the added information that the patient had a "weak spell" during the afternoon, followed by free sweating. Arrangements were immediately made for consultation with a surgeon.

March 29th.—Dr. Jacobson saw the patient with me at 8.30 A.M. At that time his pulse was 90; temperature, $99\frac{4}{10}$° F. He had passed a pretty good night; tumefaction more noticeable even than yesterday, and the tumor distinct and larger. It was agreed that an immediate operation was imperative. Arrangements

[1] Read before the Onondaga County Medical Society, May 8, 1894.

were accordingly made and abdominal section was done at 3 P.M, the tenth day after onset of symptoms. The appendix was gangrenous throughout its entire length, and was embedded in a large blood-clot, under which were about two ounces of foul pus. The patient made an uninterrupted recovery and is now about the house.

Case III.—P. W. G——, aged thirty-one, Scotchman by birth; tall and slim Of good family and personal history. Went to Toronto, Canada. March 28, 1894, at 3 P.M. was attacked with cramps in the bowels, and with vomiting, but no diarrhœa, which he attributed to the drinking-water. He returned to Syracuse by the earliest train, and called me the following evening.

In addition to the above history, an examination revealed considerable fulness of the abdomen; no tumor or tumefaction, but distinct tenderness at McBurney's point. His pulse was 100, and his temperature $101\frac{5}{10}$° F. His bowels had not moved in two days so he was given sulphate of magnesia and carbonate of magnesia, in moderate doses, in peppermint-water every hour until his bowels moved freely, and Tully powder sufficient to control excess of pain.

March 30th.—Pulse, 92; temperature, $99\frac{5}{10}$° F.; bowels had moved three times; abdomen flat, and no pain except on motion. Tenderness is marked, and dulness in the right iliac fossa was detected, but no distinct tumor. At 10 P.M. Dr. Jacobson was called in consultation. Pulse, 84; temperature, 101° F.; symptoms unchanged, but, in addition to slight dulness, could detect slight tumor in the region of the appendix. It was agreed to continue conservative treatment, but to be ready for operation at any moment.

March 31st.—Pulse, 82; temperature, 99° F., in the morning, and pulse, 80; temperature, $98\frac{5}{10}$° F., in the evening, with improvement of all the symptoms.

April 1st.—Pulse, 72; temperature, $98\frac{4}{10}$° F. No pain, little tenderness, but tumor distinct.

April 2d.—Pulse, 70; temperature, 99° F. All symptoms favorable.

April 3d.—Pulse, 80; temperature, 101° F. Bowels moved twice, and had twinges of pain previous to each movement Tumor somewhat increased.

April 4th.—Pulse, 90; temperature, $100\frac{8}{10}$° F.; respiration, 22. Considerable pain during the night; tumor increased in size, and tumefaction evident on extension of right leg. Dr. Jacobson was called and an operation agreed upon, which was performed at 3 P.M. A post-cæcal gangrenous appendix, surrounded by about an ounce of vile pus, was removed; and the patient is now convalescent.

Case IV.—W. B——, aged twenty-five, English by birth; an engraver. Was seized with pain in the stomach and vomiting late in the evening of April 24th. The pain persisting and the vomiting, bilious in character, continuing, he sent for medical aid in the afternoon, and was seen by Dr. Jacobson at 3 30 P.M Examination showed that his pulse was 105; temperature, $101\frac{3}{4}$° F.; abdomen dull on both sides over a great portion of the area below the umbilicus; sensitive at various points, and most tender to pressure about an inch below McBurney's point; tongue, dry in centre and brown; pains paroxysmal. Salol, phenacetin, and pepsin were prescribed. At 11 P.M. patient was seen again; he had had no severe pain since afternoon visit and had not vomited; pulse, 90; temperature, 100° F.; tongue more moist; abdomen softer; dulness limited to cæcum; marked tenderness on pressure in right iliac fossa. He was prescribed, hourly, fifteen grains of sulphate of magnesia and five grains of carbonate of magnesia.

April 26th.—Patient had rested so well that he had little medicine; pulse, 72; temperature, $98\frac{4}{10}$° F.; abdomen a little more tympanitic; tongue moist, slightly furred; no changes in dulness; diminished tenderness. Saline mixtures to be continued. At 6.30 P.M., pulse, 80; temperature, $99\frac{2}{10}$° F. Patient had vomited once during the day; local symptoms and signs unchanged; bowels not having responded to salines, enema was advised.

April 27th.—Passed a comfortable night; vomited once on getting up to help himself to milk; bowels had moved very freely; tongue a little dry; pulse, 80; temperature, $99\frac{2}{10}$° F.; local symptoms unchanged. At 10.30 P.M. I saw the patient in consultation with Dr. Jacobson. Pulse, 72; temperature, $99\frac{1}{10}$° F.; abdomen flat and soft; dulness in limited area in right iliac fossa below the line from the umbilicus to the anterior superior spinous process, and tenderness confined to this area. As his general symptoms had improved since an earlier evening visit, and the local symptoms had not progressed, it was agreed to send the patient to the hospital early in the following morning and meet there in consultation, prepared for operation, if indicated.

April 29th, 8.30 A.M.—Patient was seen in St. Joseph's Hospital. He had passed a restless night, but without severe pain; area of dulness was increased very slightly, and degree of tenderness was heightened; pulse, 68; temperature, $100\frac{2}{10}$° F. Because of the increase in local manifestations it was agreed that the operation should be done at once. An intensely congested, mahogany-colored appendix and mesentery of unusual development, with points of degeneration, evidently on the rapid road to complete tissue-death, were removed; and this patient is now on a fair way to recovery.

Four cases are very few from which to make deductions of absolute value, but when they are fair representatives of all forms of acute septic appendicitis which have come under our observation in the past, the total number of which is considerable, they are worthy of consideration.

The physician is the person who, ordinarily, is first called to see the patient suffering from appendicitis. The existence of bellyache is not commonly associated with the thought of the surgeon and his knife in the mind of the average man. Accordingly, an ability to make an early diagnosis and to appreciate the relative value of the symptoms and physical signs is, for the physician, of the utmost importance; but of still greater importance is the ability not only to determine the proper medical aid to be extended, but to decide when surgical interference is to be invoked.

Let us first consider the early symptoms presented in these cases. They were abdominal pain and tenderness, vomiting, diarrhœa or constipation, fever, and an accelerated pulse.

The abdominal pain was the initial symptom in each case. It preceded the vomiting, the diarrhœa, and the consciousness of tenderness, and the fever and the increase of pulse-rate followed in its train. It was not distinctly localized at first in any case, but in from twelve to twenty-four hours it was distinctly felt by the patient to be most intense in the right iliac region, and, when paroxysmal, to radiate thence. The pain varies in character. It may be paroxysmal and intense, suggesting colic; or it may be dull and constant. In either case it was always exaggerated by motion and by pressure, so that the patient assumed a position protecting the affected parts to the greatest possible extent. In walking, he bends forward; in bed, he is easiest lying on the right side with his knees drawn up. Pain is a common symptom of all abdominal disturbances; but pain, at first vaguely defined, but soon distinctly localized in the region of the appendix and increased by motion, is of itself almost pathognomonic, and could exist in acute diseases in only a very few other pathological conditions, which fortunately have distinctive symptoms of their own, like invagination, volvulus, and stercoral typhlitis.

Tenderness always accompanies pain. There may be several sensitive places in the abdomen, as observed in one of these cases, but careful palpation, with a single finger-tip, will locate the point of greatest tenderness exactly over the origin of the appendix. McBurney has rendered us the greatest service in giving us an exact point at which the appendix originates in all normal

cases, a point one and a half to two inches from the anterior superior spinous process of the ilium, on a line drawn from it to the umbilicus. In the fourth case reported, the point of most exquisite tenderness was located nearly an inch below this line, but the short, thick, inflamed appendix was disengaged from exactly the region diagnosed. In my experience this is the only instance of displacement of the appendix, even to so slight an extent; but there are many cases recorded where the appendix has occupied an unusual position, as under the right lobe of the liver and even in the left iliac fossa.

Dr. Edebohls, at the last meeting of the New York State Medical Society, read a paper demonstrating the possibility of palpating the appendix, in every case where the abdominal wall is not too thick, by deep pressure from above with counter-pressure from the posterior wall of the abdomen, in a line from the umbilicus to the spine of the ilium. I do not question but that a practised observer could attain such precision, but in cases of acute appendicitis the procedure is unwarrantable, except in the very inception of the disease, as the force necessary to compress the abdominal tissues against the posterior abdominal wall would be sufficient to rupture a degenerated appendix.

Vomiting was a symptom present in each of the cases. Of itself it is a symptom of little value; but, in connection with those already mentioned, aids in the formation of a diagnosis. The vomiting in all the cases which I have seen has been most severe in those following gross indiscretion at the table. It has seemed to me possible, that just as vomiting mechanically empties the stomach and the liver, and even the trachea and large bronchi, so it might mechanically force some of the contents of the cæcum into the appendix and thus originate conditions of overdistention, giving rise to strangulation and inflammation of this organ, particularly where colonies of *bacilli coli communis*, virulently active in fermenting intestinal contents, were forced through the so-called valve of the appendix. But I do not know that any such origin of appendicitis has been demonstrated or suggested.

In two of our cases diarrhœa was marked, and in these two there was a distinct history of most indiscreet ingestion of a large amount of food difficult of digestion. My other cases bear out this observation. In two, constipation was marked, so that neither diarrhœa nor constipation can be considered as diagnostic of this disease. Either condition seems to depend on other factors than the existence of an inflamed appendix.

Fever was not an initial symptom in any of these cases, though it developed in each case sooner or later, and was, in none of them, a symptom upon which reliance could be placed, either for early diagnosis or for prognosis. In the first case, where septic peritonitis had developed within twenty-four hours, the temperature was lower on the day of the operation than on the day before.

In the fourth case, the temperature and the pulse were both near the normal at the time of the operation and had not been high at any period. In both of these cases there was no attempt at walling off the seat of the inflam matory action from the rest of the abdomen. In the second and third cases the temperature, at first elevated, returned to the normal with the amelioration of the primary symptoms, and became gradually elevated with the development of the tumor. In both of these cases an abscess cavity was established, more or less perfectly, protecting the adjacent tissues from infection. With the establishment of septic peritonitis, in the first case, the pulse became more rapid and of wretched character, and at the same time the temperature fell; a similar phenomenon has been observed in four other cases of fulminating appendicitis with very rapid general infection that have come under my notice.

For a primary diagnosis I regard the pulse and the temperature as of very little importance. On the other hand, the increased pulse rate and the elevation of temperature attending the development of the tumor, seem to indicate the formation of a perityphlitic abscess; and a greatly increased pulse-rate, with lessened volume and strength, and with a falling temperature, is suggestive of general septic infection.

To sum up: Right-sided abdominal pain, increased by motion and by pressure, with tenderness on point pressure most exquisite over the origin of the appendix, with vomiting, and some disturbance of the circulation and temperature, coming on suddenly in a person previously healthy, are sufficient to establish a diagnosis of acute appendicitis.

The discussion of the prognosis and the indication for surgical treatment I shall leave to my collaborator.

It remains for the physician to say when the surgeon shall be called in consultation. To this, the only answer must be, so soon as a diagnosis is made. I know of no absolute signs that unequivocally indicate the moment when medical aid is of no further utility, and when, to save the life of the patient, surgery must be resorted to. The surgeon should be associated with the physician from the outset, and should share with him the responsibility of the case, and to his experience and judgment must be referred the question of the necessity of any operation and the time when it should be made.

Concerning the medical treatment, little need be said. Locally, cold alone is appropriate in the beginning, and is best applied by the coil. If tumor is forming and is slow in development, heat may be of utility in hastening the process. This was exhibited in the second case, seen four days after its inception, and operated on the tenth day.

Internally, opium is, in my opinion, by far the most appropriate in all cases where it agrees; and no fears of "masking the symptoms," as some surgeons put it, should be entertained. This drug gives physiological rest; and, more than that, it controls the inflammatory process, actually diminishing the calibre of the arterioles of the mesentery and peritoneum better than any other drug yet used.

If the colon be filled with fecal matter, a mild saline, just sufficient to remove this cause of embarrassment, is appropriate, and for the purpose I know of no prescription superior to the one used in our cases, namely, fifteen grains of sulphate of magnesia, with five grains of the carbonate of magnesia, in half an ounce of peppermint-water every hour until the desired result is obtained. This mixture is well borne by the stomach, and is efficient after a few doses. The diminution of the abdominal contents, from the emptying of the gut of fecal matter and of gas, was most marked in the cases where it had been used, and, at the time of the operation, the freedom from interference of inflated intestines much facilitated the operation.

If general peritonitis develop, possibly the saline treatment alone is more scientific; but of this I confess I am not yet thoroughly convinced. In such an event I have yet to see a case which has recovered from either medical or surgical treatment, however skilfully it may have been applied.

Salol is of great value, as in so many intestinal diseases, by its efficiency in controlling fermentative processes in the intestinal canal.

The diet should be entirely restricted to fluids; and, so long as vomiting continues, nothing but barley-water or oatmeal-water or ice-water should be permitted. With the amelioration of the primary symptoms diluted milk, with a tablespoonful of lime-water to each glass, may be allowed.

If these cases, as well as all the others I have seen, teach anything, it is that an early diagnosis, the timely association of a surgeon in the management of the case, and the harmonious working together of the physician and surgeon will save many valuable lives that otherwise might be lost to the world.

FOUR RECENT CASES OF ACUTE APPENDICITIS, CONSIDERED FROM THEIR SURGICAL ASPECT.

By NATHAN JACOBSON, M.D.,

SYRACUSE, N. Y.

PROFESSOR OF CLINICAL SURGERY, COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY; SURGEON TO ST. JOSEPH'S HOSPITAL.

BEFORE entering upon a consideration of the surgical questions in the cases under discussion, permit me to complete their records as given by Dr. Heffron.

CASE I.—G. K——, seen at 4.30 P.M., July 27, 1893. Although the temperature had fallen since the morning from 102.5° to 101° F., the increase in the pulse-rate from 100 to 116, and the marked aggravation of local signs indicated rapid progress of the inflammatory process. It was therefore decided to operate at once. The preparation was hastily made. Despite anæsthesia the patient strained constantly throughout the operation. His chest was more or less filled with mucus, and respiration in consequence impeded.

A straight incision along the dextral border of the rectus muscle was made, about three inches in length. Immediately upon incising the peritoneum there was a profuse discharge of sero-pus. Upon the deeply injected intestines, at various points, inflammatory deposits were present. As soon as the peritoneal discharge was removed, the appendix was sought for and easily found. Readily separated from its slender adhesions, it was seen to be angry, swollen, and perforated, and so gangrenous that in the attempt to seize and draw it up the forceps broke off its end. Liquid fæces exuded from its perforations. It was cut off close to the cæcum, the stump cauterized with pure carbolic acid, and the presenting surfaces irrigated with a saline solution. A glass drainage-tube was carried down to the stump, and about it iodoform gauze was introduced, and the ordinary surgical dressing applied.

At midnight the patient was seen again. His temperature had gone to 102.8° F.; the pulse was so feeble that it could hardly be counted. A great amount of bronchial secretion was present. The lips were blue, the extremities cold and discolored, respirations were frequent. The surface dressings were badly stained and therefore changed, and strychnia, digitalin and nitro glycerine administered hypodermically.

At nine o'clock in the morning the patient was found to be bright, and reported himself as feeling materially better. His pulse, however, was not improved; temperature, 104° F.; lessened bronchial secretion permitted freer breathing, the abdomen was distended, tongue dry, urine had not been voided. From this hour the patient steadily failed, the pulse soon became imperceptible, the patient collapsed, and death resulted at 1.30 P.M.

Dr. May made a bacteriological examination of the appendix and reported that it presented a pure culture of the bacillus coli communis.

CASE II.—R. H. L——. Seen on the tenth day of his attack at 9 A.M., March 29, 1894, temperature was 99.5° F., pulse, 90. The local manifestations were entirely out of proportion to the mildness of the constitutional one. The right leg and thigh were flexed. Upon extending the extremity the right side of the abdomen became immediately prominent. An area of dulness present in the right iliac fossa, reached within one-half of the median line. A localized tumor was evident; fluctuation could be made out. Diagnosis of appendicicular abscess was made, and operation advised.

At 3 P.M. an oblique incision was made over the outer border of the tumor, that is, about an inch from the brim of the pelvis, its centre opposite the anterior superior spinous process. The peritoneum when reached was found to be tense. Upon incising the tumor, pus and blood were discharged. The abscess cavity was thoroughly walled off. It was occupied by an infectious thrombus, in the centre of which was the gangrenous appendix, collapsed and in a state of sphacelus. The slightest effort to remove the blood-clot awakened profuse bleeding. The cavity was therefore irrigated with a hot normal saline solution and packed with iodoform gauze. Throughout the operation the patient, who was suffering from an acute bronchial catarrh, took ether so wretchedly that the anæsthesia gave us more trouble than did the operation.

Just before the operation the temperature was taken, and was found to be 101.5° F. It steadily fell to normal, at which point it was found at 10 P.M. On the following day there was a slight rise to 100.2° F., but after this it remained substantially normal. On the second day after operation, the dressing being removed from the abscess cavity, it was irrigated with a sublimate solution of 1 to 8,000. The blood-clot was easily washed away and no further bleeding occurred. The dead portion of the appendix separated spontaneously. April 1st its stump could be seen already covered by granulations. The entire abscess cavity cleansed itself, and five days after the operation presented nothing but a healthy granulating surface. Iodoform gauze was carried gently to the bottom, protecting the stump of the appendix, but firmly packed at the surface in order to distend the opening. Within a short time the wound was thus rendered funnel-shaped. The cavity granulated rapidly from the bottom. May 1st, it being entirely healed, an abdominal supporter was applied and the patient allowed to be up and about.

CASE III.—P. W. G——. At the visit, made late in the evening of March 30, 1894, the third day of his sickness, an examination revealed the presence of a large area of dulness in the right iliac fossa, describing a quarter of a circle, with a radius of at least three inches. Within this tumefied area we were able to recognize as more distinct a tumor located opposite the anterior superior spinous process. There had been improvement in pulse, facial expression, and general condition, although the temperature was not reduced. With this condition we felt justified in deferring the operation for the night. Dr. Heffron reported the improvement in local and general manifestations on the following day to be so decided that it seemed possible that the patient might recover without operation. I did not see him again until 10.30 A.M., April 4th, the eighth day of his sickness. The tumefaction had in the meantime entirely disappeared, and a distinct tumor, two inches in length and one and one-half in width, was present opposite the anterior superior spinous process. It reached externally to the brim of the pelvis. Temperature, 101° F.; pulse, 80. Operation was acceded to, and as soon as preparations could be completed was undertaken. An oblique incision four inches in length was made about three-quarters of an inch from the brim of the pelvis, well toward the outer border of the tumor. Upon carrying the incision downward, despite its extreme dextral location, I entered the free peritoneal cavity. The following condition was found: A loop of small intestine adherent to the cæcum was directly under the incision, both large and small intestines were of normal appearance, the tumor lay posterior to the cæcum and well against the outer border of the pelvis.

Protected by firm adhesions at this point from the general peritoneal cavity, it was apparent that it would be both difficult and hazardous to enter the abscess cavity through the abdominal route. The incision into the peritoneum was therefore closed and the transversalis fascia sutured over it. Through the same surface incision I now dissected closely to the brim of the pelvis, until I reached a point deep enough to feel the tumor behind the cæcum. In doing this, at the upper angle of the incision, the omentum came into view. Surrounding the abscess cavity with gauze pads I incised it. It contained offensive pus, and a long, cord-like, gangrenous appendix. The pus was carefully mopped out. At the lower angle the abdominal cavity was likewise entered and protected by gauze pads. Everything being thoroughly cleansed with a 1 to 1,000 sublimate solution, the appendix was tied off as close to its base as possible. Here it was surrounded by a firm exudate. Iodoform gauze, carefully folded to prevent any ravelling, was first carried down to the bot-

tom of the wound to protect the intestines below, and then above against the omentum. Finally the cavity proper was filled. The usual surgical dressing was applied.

Temperature before operation, 101.8° F., at 10 P.M. 98 8° F.; pulse 75. The following morning, temperature 99° F.; pulse, 75; no vomiting had occurred. Catheterization was necessary the first night, but not again. The dressings were not removed until the end of the third day, at which time it was found that protective adhesions existed on all sides. The odor, however, was very strong. The skin, for an area of two inches, was found reddened and infiltrated, and upon lifting up the inner flap the muscular tissues as well as the aponeuroses, infected by the discharge, had become gangrenous. For the following four days care was required in dressing the wound. All gangrenous structures were thoroughly removed, sublimate solution, 1 to 1,000, was carefully rubbed into every nook and corner, and in this manner by April 12th all dead structures had been cleared away and the entire wound surfaces presented healthy granulations. From this period the patient progressed rapidly to a complete recovery.

Case IV.—W. B——. During the first twenty hours of his sickness he received no medical attention. At my first visit, pain, vomiting, fever, but without characteristic local manifestations, were present. In the course of seven hours marked improvement in the general symptoms occurred. Tenderness at a fixed point in the right iliac fossa appeared and continued. The fecal collection in the cæcum was cleared away by the exhibition of salines. The morning visit, on April 27th, disclosed the following condition: Temperature, 99 2° F.; pulse, 80; he had passed a comfortable night; the tenderness remained undecreased; there was no dulness. By evening, however, the patient, having passed the entire day comfortably, sleeping most of the time, exhibited a temperature of 100.6° F., and for the first time there was an area of dulness lying a little higher than the point of tenderness, not well defined but readily recognized. The disease was evidently progressing. Dr. Heffron saw him soon after with me and confirmed the diagnosis, but agreed that operation could be deferred until morning. He was taken to St. Joseph's Hospital at 8 A.M., April 28, 1894. His pulse was 68, firm and regular; temperature, 100.2° F.; tongue was moist, area of dulness increased and now about two inches in length and one in width. He was prepared for operation.

An oblique incision was made four inches in length and one inch from the anterior superior spinous process. Upon opening the peritoneal cavity, there was no discharge of serum or pus; the cæcum was readily recognized, drawn inward, and the presenting abdominal structures were covered by gauze pads wrung out of a sublimate solution. The finger recognized the appendix, which upon being lifted out was found to be deep purple in color, greatly infiltrated, with an equally thick mesentery adherent to it, throughout its entire length. Its free extremity was on the point of gangrene; upon the mesentery, beginning ulceration was evident. The entire mass was about two inches in length and one and one-half in its transverse diameter. The appendix and its mesentery were ligated separately with silk, and the few drops of pus which were extruded were caught as it was severed. Everything was carefully washed with a sublimate solution of 1 to 1,000. At no point was there evidence of adhesions. Iodoform gauze was carefully packed about the stump, walling off the omentum and intestines. The peritoneum and abdominal walls were sutured to within an inch of the lower end of the incision and the wound dressed as usual.

At the conclusion of the operation, the patient's pulse was 69, and, at 5 P.M., temperature, 98.5° F.; pulse, 68. The outer dressings were changed on the following day, but the packing in the wound was undisturbed until the fifth day. He required catheterization on the night following the operation. Temperature until the day before the change of the deeper dressings were made, reached no higher point than 100° F.; at this time, however, it was 101.2° F. The wound was carefully irrigated with a normal saline solution, cautiously dried and carefully packed with iodoform gauze. The wound cavity could be seen to be outlined by the intestines covered with a grayish layer of inflammatory exudate. It was thought advisable not to disturb the bowels until the sixth day, when they were moved by an enema. On the seventh day, three one drachm doses of Epsom salts, at intervals of four hours, were administered, and a large movement was secured, followed by two other watery discharges. The abdomen was at no time distended. General abdominal tenderness and a dry tongue were present on the day following the operation, but after this no symptoms suggesting peritoneal disturbances appeared. The patient made an uninterrupted recovery.

Section of the appendix disclosed the presence of pus. At its free extremity, corresponding to the site of gangrene, was an infectious thrombus. Upon bacteriological examination, Drs. May and Levy report having found a pure culture of the bacillus coli communis.

The four cases to which your attention has been invited this afternoon, present varying types of acute infectious inflammation of the appendix. The first, because of its malignant and rapidly progressive character, is described as fulminating. In the second and third, the inflammatory process reaching beyond the appendix, and invading peri appendicular structures occasioned abscess formation. In the second the pus collection was superficially placed, but in the third it was buried behind the cæcum. The fourth case, beginning probably as a catarrhal appendicitis became changed in character by the occurrence of an infectious inflammation of the blood-vessels.

What to do for a given case of appendicitis, at once becomes a most serious question. Which cases will progress happily without surgical aid and which can be saved by timely operation, are the questions, the answer to which requires not only rare diagnostic acumen, but, in their management, careful medical and energetic yet painstaking surgical intervention.

I am less ready than I was eighteen months ago to maintain that much the larger percentage recover by medical treatment alone. Every case of appendicitis should be seen during its first twenty-four hours so frequently that the physician can satisfy himself of either decided improvement in both local and general manifestations or detect any disposition to progression. The wise course is that, from the outset, the case should be watched by both physician and surgeon. Of the two, I believe more stress should be placed upon the local than the constitutional manifestations. If there be equal disappearance of both general and local symptoms during this period, there is no need to feel that surgical aid is to be invoked. Aside from the careful administration of salines and intestinal antiseptics, the less medicine prescribed for the patient, the better. Nothing should be administered which in any way is to mask the symptoms; the exhibition of opiates, by relieving the pain, lulls the patient into a feeling of security and prevents his proper conception of the degree of his suffering.

The only safe rule to follow is, that evidence of continued progression at the end of twenty-four to thirty six hours justifies and indeed calls for operation. Even the cases remaining stationary during this period must be viewed with suspicion. The cases presented in these papers indicate very clearly that there may be mitigation of all and complete disappearance of most of the symptoms and yet during the period of their subsidence the diseased process has gone on steadily. The pulse may become lowered, the temperature sink to normal, and all this time gangrene may be advancing or ulceration imminent. With improvement in constitutional symptoms, the local signs demand the closest attention. An increase of tenderness, the appearance of tumefaction, the development of a tumor, mean much more than any

variation in pulse and temperature, or the feelings of the patient. The first evidence of dulness in the fourth case, despite apparent general improvement, was the signal for operative intervention.

When the patient is overwhelmed by an infectious inflammation as virulent as that presented in the first case, or when septic peritonitis has manifested itself as a later complication, the hope of aid by medical means is generally abandoned. But under these circumstances the surgeon's art is equally powerless. It is in the other group of acute cases, with less violent manifestations, that it becomes a question of vital moment to decide when the opportune time for operation has arrived.

Operations are described as early and late. An early operation implies its performance during the period in which the inflammation is still limited to the appendix. The element of time is not the only consideration in determining whether or not the operation be early. If during the first twenty four hours of an appendicular inflammation the infection has spread through the lymph-vessels of an unperforated organ, or has extended from one disorganized and involved the entire peritoneal cavity, it is evident that the operation then performed is early in point of time, but too late to avert wide spread and probably fatal septic inflammation. On the other hand, an operation performed on the third day, as in our last case, while not done upon as early a day, was still timely, for by it we did no doubt avert septic peritonitis.

Late operations are those performed after abscess formation has occurred, walled off by firm adhesions; the mere incision of these abscesses is a comparatively simple operation. But during the period of their formation it is often a matter of great difficulty to determine whether the patient's chances may not be improved by delaying operation until nature has rendered her fullest assistance. There is a group of cases seen from the third to the fifth day of sickness, when, as Richardson puts it, we may hesitate whether we may not be too late for an early operation and too early for a late one. Done at this period, he believes no operation in surgery more difficult than the removal of the appendix without infecting the general peritoneal cavity. This situation presented itself in our third case. At the end of the third day a tumor was beginning to form in the midst of the tumefied area. An operation done at this time would have been an entirely different procedure from the one undertaken on the eighth day.

To perform a radical operation, the rule must be, operate early. That this injunction adds greatly to the security of the patient, is apparent in studying the results obtained by Fowler in 127 cases operated on by him. Of 58 operated on during the first three days, eighty-three per cent. recovered; of 9 on the fourth day, sixty-six per cent.; of 26 on the fifth and sixth days, fifty-eight per cent.; of 18 on the seventh and eight days, fifty per cent.; while of 9 on the ninth and tenth days, thirty-three per cent.

The great fatality attending his late operations is not in accord with my experience. The operator probably sought to do more than give vent to the contents of the appendicular abscess, and by breaking down the protective barriers, infection gained admission into the peritoneal cavity.

Increasing experience adds to the operator's ability to deal with these cases. Preparations for the operation must be hurriedly made. These cannot be as thorough as in an ordinary laparotomy. The operator may be handicapped by the facilities at his disposal. The surfaces purified as well as possible, the site of his incision is selected according to the period at which the operation is undertaken. The length of the incision should be sufficient to afford the most free access to all diseased surfaces. Dealing with an acute infectious inflammation, nothing is calculated to produce more serious consequences than an inadequate incision, which must prevent both the protection necessary for the abdominal viscera and the delicacy of manipulation absolutely required. In our first case the incision was vertical, along the outer border of the rectus muscle. This was indicated because the acuteness of the attack foretold that we would be obliged to enter the free peritoneal cavity. Evidence of septic peritonitis at once encountered, presented the most dubious outlook for the patient.

The steps taken in the course of the operation have been indicated in the history. A glass drainage-tube was used in the first case. In the operations which I have performed since that time, I have used only gauze drainage, and have reason to believe that this procedure is much the wiser one. The abdominal cavity was irrigated with a saline solution. Although this receives the strong endorsement of most of the surgeons it was futile with us. The Germans say that "Spuelerei ist Spielerei"—that is to say, "irrigation is child's play."

Of thirty-two cases in which general peritonitis was encountered by Fowler, not a single recovery occurred. Others claim to have been more fortunate. This has, however, been my experience in three cases in which I encountered it in operating.

In Case IV., in which likewise an early operation was undertaken, we were fortunate enough to secure the removal of the appendix with its mesentery, the one about to become gangrenous and the other on the verge of ulceration, before further infection had been awakened. No adhesions were present, but the greatest care was taken to protect by gauze pads all visceral contact with any infectious matter. The appendix and its mesentery after ligation presented a stump so broad and infiltrated that it was impossible to undertake what in chronic cases is an ideal step, namely, to dissect up a cuff of the peritoneal investment, invert the remainder of the stump, and secure the serous coat over it by a Lembert suture. We were obliged to content ourselves with its purification by means of the sublimate solution and the thermo-cautery.

Iodoform gauze was carried into the wound. The four strips carefully placed around the stump were infolded in such a manner as to prevent a free edge of the gauze presenting itself at any point. This is essential, that none of the threads may adhere to the abdominal structures, and greatly facilitates the removal of the packing. Allowed to remain for four or five days, nature throws about the gauze a protective wall. This usually averts future general infection.

The second case was of all the most simple, but exhibits a pathologic peculiarity, which as far as I can learn is quite unique. The destructive process had evidently reached the vascular supply of the appendix. The vermiform process, collapsed and gangrenous, was found imbedded in an infectious blood-clot. The surgical steps taken with this patient have been amply justified in his very rapid recovery. The wound quickly cleansed itself, and in fact it has never been my experience to see a cavity fill up so quickly as did this. Great aid to its accomplishment was the manner in which the gauze was inserted. At each dressing, by carefully carrying it to the bottom of the wound, lightly placing it here, and then distending the upper portion as much as possible by firm packing, we secured within a few days a funnel-shaped wound, sloping gently from the sides to the centre, and gave it at the same time the largest possible area for granulation.

Case III. presented a most serious surgical problem. The incision was made well toward the pelvic brim, inasmuch as it was recognized that the tumor could thus be more easily reached. In taking this step, we disregarded the usual instructions given, which are to make the incision over the most prominent portion of the tumor. This was also done in Case II. It seems to me wiser in performing a late operation to attempt, if possible, to establish an extra peritoneal route. This is accomplished better by making the incision as far outward as possible, rather than over the most prominent portion of the tumor.

After entering the peritoneal cavity, two courses were

left open to us. Good surgeons state that with post-cæcal abscess, it is sometimes necessary to reach it by the abdominal route and to drain through the unimplicated intestinal structures. Aside from the impossibility of securing drainage through an up hill channel, the virulent infection which manifested itself within a few days after the operation in this case and produced such destructive gangrene of the abdominal walls, I believe shows the wisdom of the course pursued. Such intense infection could not have been withstood by the intestines, and must have produced a rapidly fatal spreading peritonitis. On the other hand, closure of the peritoneum and the transversalis fascia over it, permitted us, by means of another incision through the muscular structures, to reach the brim of the pelvis, and by careful dissection the abscess was exposed and entered through its outer wall. Even here we could not avoid exposing the omentum above and the intestines below. After three days, however, protective adhesions sealed up the extremities of the abscess cavity and free drainage was permitted. More than this, the removal of all gangrenous structures was made possible. The appendix was readily exposed and removed. Again the use of iodoform gauze, placed after the manner described, secured not only limitation of the abscess cavity, but also the desired funnel-shaped wound.

The recommendation to enter these abscesses by incision through the rectum, it is evident could not have yielded as satisfactory a result. The fear that extra-peritoneal incision in the late cases may not be sufficiently radical, because of the possible existence of multiple abscesses, is, I believe, no longer regarded as well grounded. These rarely, if ever, occur late, although frequently present early. In both of the cases reported the sudden recurrence of fever indicated to the medical attendant that the opportune moment for operation had arrived.

The importance of the surgical attention required by these cases after operation is not sufficiently appreciated. I esteem it the duty of the surgeon to personally superintend the change of dressings until there is no further possibility of infection. This can be done many times only at a great sacrifice of time, but the best interests of the patient demand it.

It must be evident that the three cases which have recovered by operation could none of them have been saved by other than surgical intervention. In the fulminating cases complicated early by septic peritonitis, the prognosis is almost hopeless. Where this complication appears at a later period, a gloomy termination is likewise to be feared. I feel confident that twenty four hours later this would have been the situation in Case IV.

With a clearer conception of the nature of these infectious inflammations and the improving technique, largely the work of American surgeons, the percentage of recoveries will probably increase in the future, if operation be done sufficiently early to anticipate the frightful results of microbic invasion. I regret that in all of the four cases bacteriological examinations were not made, but in two the facilities for the same were not at hand.

The increasing importance given each year to the surgical treatment of infectious appendicitis may be regarded by some as uncalled for and unjustifiable. From my standpoint, however, it is directly in the line of conservative surgery. We remove a part not essential to the animal economy, but thereby we have saved life.

Laws Relating to the Practice of Pharmacy.—The Agricultural Department in Washington has published a report upon the laws regarding pharmaceutical practice in the different States and Territories of the Union. It shows that there are no laws on the subject in Idaho, Indiana, Montana, Nevada, Arizona, and the Indian Territory. In Maryland, there is a law which applies, however, only to the city of Baltimore. The compilation is based on reports made by the various State pharmaceutical associations.

THE THYROID TREATMENT OF PSORIASIS, AND OTHER SKIN DISEASES.

By GEORGE W. CRARY, M.D.,

NEW YORK.

ASSISTANT ATTENDING SURGEON, ROOSEVELT HOSPITAL, OUT-PATIENT DEPARTMENT.

SINCE Davies and Bramwell reported their remarkable results following the use of thyroid preparations in psoriasis and some other diseases of the skin, the method has been perhaps somewhat widely employed, though but comparatively few reports have been published. Below I give briefly the histories of nine cases of psoriasis that I have had under this treatment for varying periods[1] followed by a short summary of previously reported cases.

CASE I.—Male, aged twenty six; disease of three years' standing, with recurrent attacks; longest period of exemption was one month. Eruption in large and small patches of general distribution. General condition fair. Temperature before treatment was 98⅘° F. Doses of glycerine extract (gr. xxiv. to ʒ j.)[2] rose from 9 to 15 drops daily, in three divided doses. Highest temperature during treatment was 100° F. After two or three days' treatment, the irritation was allayed. Complained of pain in joints. Treatment continued for two weeks. No improvement.

CASE II.—Male, aged thirty six; seven months' standing; small spots general in distribution; very irritable. Temperature before treatment was 100⅛° F. Dose of extract was 9 to 18 drops daily. During treatment temperature varied from 97 ½° to 98⅛° F. Irritation much lessened. General condition improved. Marked sheep odor to perspiration. Treatment continued for five weeks. No improvement.

CASE III.—Female, aged thirty nine; eruption for two and one half years, in spots over body with exception of face, neck, and chest. General condition good. Temperature before treatment, 99° F. There was considerable hypertrophy of thyroid gland. Dose of extract was 15 to 40 drops a day. Temperature during treatment, 98⅘° F. Irritation allayed. Duration of treatment was six weeks. No improvement, and even grew worse.

CASE IV.—Male, aged twenty-five; two years' standing, but disappears in summer; small spots upon arms and chest. General condition poor. Temperature before treatment was 98⅗° F. Daily amount of extract, 15 to 45 drops. During treatment temperature between 97° and 97½° F. Skin between spots much softened. Irritation lessened. Pain in arm. General condition improved. Duration of treatment was eight weeks. No improvement.

CASE V.—Male, aged forty-six; eruption for ten years, severe and general. General condition poor. Temperature before treatment, 99½° F. Daily amount of extract was from 15 to 36 drops. Temperature during treatment between 97° and 99° F. Skin between patches became soft and velvety. Irritation lessened. Sheep odor very pronounced. General condition improved. Treatment continued for twelve weeks, with one interruption of two weeks. Eruption much improved.

CASE VI.—Male, aged fifty; eruption for twenty years, and is general and severe. General condition poor. Temperature before treatment, 98½° F. Daily amount of extract varied from 15 to 75 drops a day. Temperature during treatment ranged from 97⅘° to 100° F. Intercurrent attack of facial erysipelas and later of cellulitis of leg, from external infection. Sheep odor very marked. Skin not affected by disease became very soft and smooth. Pains in joints. Treatment continued for eleven weeks. Very marked improvement.

CASE VII.—Female, aged thirty; disease of ten years' standing; small spots upon upper and lower extremities and upon chest. General health is fair. Tem-

[1] These cases were treated at the Out-Patient Department of the Roosevelt Hospital with the kind permission of Dr. Frank Hartley, the Attending Surgeon.

[2] MEDICAL RECORD, June 17, 1893.

perature before treatment was 100½° F. Daily amount was from 15 to 60 drops. Temperature during treatment varied from 97° to 99⅘° F. Irritation very much allayed. Skin not affected became soft and smooth. Treatment for fourteen weeks. No improvement.

Case VIII.—Female, aged thirty; two years' standing, not severe but general. Temperature before treatment, 98⅘° F. Daily amount was 10 to 30 drops. Temperature during treatment, 98⅘° F. Treatment continued for three and a half weeks. No improvement.

Case IX.—Female, aged twenty-three; disease of two years' duration, and upon legs and thighs. General condition fair. Disease persisted throughout a recent pregnancy. Temperature before treatment, 99° F. Daily amount taken was from 15 to 30 drops. Temperature during treatment varied from 98⅘° to 98⅘° F. Irritation not lessened. Pain in back. Duration of treatment was five weeks. No improvement; grew much worse.

We have here nine cases of psoriasis, in which improvement has been noted in only two, and in these two the response to the treatment has been very slow and not distinctly progressive. It may be objected that in some of these cases the treatment has been of short duration, but where cures have been reported the improvement became manifest very early. That the thyroid has a beneficial effect upon the skin in myxœdema is most certain, and indeed it is equally certain that in other conditions such an effect is produced, for in all the above cases the skin between the patches or spots of the eruption became soft and smooth. The thyroid extract has a very profound effect upon general nutrition, and perhaps especially upon the skin, and to this is due the changes noted. I have been struck in the above cases with the absence of a rise in temperature following the treatment, for in most of the cases the temperature has fallen to the subnormal and remained there, the fall roughly being in proportion to the dose. In some the rheumatic pains, frequently noted during thyroid administration, were present and complained of. In many of the cases there was a marked and unpleasant odor of mutton or lamb to the perspiration.

Below I give a short table of the cases of psoriasis treated by thyroid, the reports of which have already appeared:

Reporter and Reference.	Number of Cases.	Cured.	Improved.	Not Improved.	Aggravated.	Average Daily Dose.	Duration of Treatment.

[1] Eleven of these improved cases received other treatment, and should therefore be eliminated in drawing conclusions.
[2] Syphilitic psoriasis, no other treatment.

We have left before us, then, including my own cases just reported, 77 cases of psoriasis which have been treated by thyroid preparations. Of these in six, or about eight per cent., the treatment has been followed by a cure. Twenty-two have been improved, but of these we must deduct the 11 cases of Abraham's which received also other treatment, and then we have 66 cases treated, with 17, or twenty-five per cent., improved. Of the 49 cases which were not benefited by the treatment, 21 grew distinctly worse.

Other diseases of the skin than psoriasis, and the re ported results are no more encouraging:

Davis: Ichthyosis, one case, improved; chronic eczema, one, improved.

Phillips: Eczema, one, no result; xeroderma, one, marked improvement.

Dill: Acne rosacea, one, no result.

Abraham: Lichen planus, 5 cases—3 improved with other treatment combined. Eczema; 7 cases—3 improved, other treatment also. Chronic urticaria, 2 cases, both grew worse. Prurigo senilis, 1 case—no result. A case of "peculiar papular eruption," 1 case—improved, other treatment. Lupus, 5 cases, other treatment also, improvement.

While then we know that in myxœdema, and in other conditions also, the administration of thyroid preparations is followed by marked changes in the skin, rendering it soft and smooth and moist, we must look upon these changes as merely nutritive, and while possibly in some cases such changes, if more thoroughly understood, could be used as an aid in therapeutics, I think we have little reason to believe that thyroid extract is in any direct way curative of any real disease of the skin or its appendages.

152 West Fifty-seventh Street.

THE MANAGEMENT OF ABORTION.[1]

By EDWARD J. ILL, M.D.,

Newark, N. J

Fellow of the American Association of Obstetricians and Gynecologists; Surgeon to Woman's Hospital; Gynecologist to St. Barnabas Hospital; Consulting Gynecologist to German Hospital of Newark, N. J.; Consulting Gynecologist to All Souls Hospital, of Morristown, N. J., etc.

The main object of a paper to be read before a society is to furnish material for discussion. With this in view it will be my object not to present an exhaustive discourse, nor an opinion of writers. I wish to present for your consideration and discussion such a method of treatment as I have followed for a number of years, and with what I consider very good results. How important this matter is to me will be shown when I tell you that I was called upon lately to treat five septic abortions in a week. I would divide the management of abortion into two parts: 1st. The prevention of abortion, and 2d, the management after we have once satisfied ourselves that the product of conception must be expelled.

It will be proper to touch upon the causes of abortion, since its prevention will in some measure depend on this factor. I consider it as very rare to count external injury, a jolt or jar, as a potent factor in the production of abortion.

At the outset we will understand that disease of the fœtus or chorion may produce abortion as well as disease of the mother. In this respect there is still a wide field for observation and study.

Among the diseases of the mother may be mentioned: Retroflexion of the uterus, chronic hyperplasia of the uterus, chronic endometritis, laceration of the cervix uteri, pelvic peritonitis, or rather its results, prolapse of uterus, syphilis, and chronic nephritis.

When we find a retroflexed pregnant uterus it will be necessary to replace it to its normal position with the greatest possible care and gentleness. This having been accomplished we may congratulate ourselves in having in all probability prevented an abortion. The same can be said of a complete prolapsus. When, however, the fifth month of gestation is over the uterus can no longer be replaced, and it either means death to the mother, or artificial interruption of gestation. In the other instances of which I have spoken, our treatment must be directed to the peculiar condition before conception takes place. An exception to some extent is syphilis and chronic nephritis. A lady of this town had aborted fourteen times in succession, and became mother of a living child after

[1] Read before a gathering of medical gentlemen at the house of Dr. S. Pierson, Morristown, N. J.

an operation for deep laceration of the cervix. Only the other day I was told of a woman who gave birth to a living and healthy child after having aborted six times before the third month of gestation. The patient was known to have syphilis, and was under antisyphilitic treatment for five months.

I believe that after longer observation we shall be able to discard the term habitual abortion, since we shall find a cause for all these cases. In the treatment of threatening abortion we are first confronted with the very important question: Are there still well-founded prospects of preventing an abortion or is it beyond our reach? If we have decided for the former the patient must be instructed to keep quiet on the first appearance of a bloody discharge or bearing-down pain, her lower bowel should be kept emptied, her diet a bland one, sexual intercourse stopped, and opium or cannabis indica administered.

When shall we know that our endeavors are in vain? The safest symptoms are when the cervical canal has dilated sufficiently to allow the finger to touch the ovum, or when the os internum is dilated to such a degree that the cervix and the corpus uteri shall form one cavity. We would also know that our endeavors are in vain when pieces of the decidua have been passed, or when there is a fetid discharge from the uterus. The latter is a sure symptom that some parts of the ovum have undergone necrosis and death.

As a rule an abortion is sure to take place when the patient has lost blood for a length of time in large quantities, accompanied with labor-pains. I have seen pregnancies continue, however, when the patients had one or two large hemorrhages, as well as I have known a child go to full term when there was a bloody mucous discharge for several weeks. When we feel certain that the product of conception will be cast off, then it becomes our duty to relieve the patients as soon as possible so as to prevent their undergoing the ordeal following retained secundines.

If we have reason to believe that the ovum is intact and the uterus is doing its work well, and gradually emptying itself, then we had better not be meddlesome. We can render the uterus valuable assistance in its endeavors by a large, hot vaginal douch or a tampon. A large, hot rectal injection will often be of signal value. Occasionally I was forced to assist the uterus by instrumental dilatation of the os externum, and then I used Goodell's dilator with much satisfaction.

So long as the ovum is intact, the uterus will probably have no difficulty in forcing it out, and when it lies in the cervical canal can be removed easily by the finger with a sweeping motion. At times we will be confronted by a severe hemorrhage, often of an alarming character. Here an iodoform gauze, or a clean cotton tampon will do its work well. It should be introduced through a large cylindrical, or a Sims speculum, and care be taken to plug the vagina around the cervix and os very thoroughly. If the uterus itself is to be plugged it can only be done through a Sims speculum, the patient lying on her back with the hips over the lower end of a table. The vagina and cervix should be thoroughly cleansed, the speculum introduced, and the cervix drawn down with a tenaculum forceps. A narrow pair of dressing forceps pushes a long narrow strip of gauze into the uterus until this organ is filled.

This is by all means the safest and surest remedy. I would warn against the use of all styptics on account of the great danger of sepsis. Occasionally we will succeed in delivering the ovum in toto by a combined abdominal and vaginal compression performed in the following way: Two fingers of the right hand are placed anterior to the cervix in an anteversion and posterior to the cervix in a retroversion, while the left hand seeks the uterus from the abdomen and on its posterior or anterior surface, as the case may be, makes pressure in the direction of the fingers in the vagina. When the ovum has been broken, or a finger once introduced into the uterine cavity, then an instrumental delivery with curretting of the endometrium becomes a necessity. It becomes a life-saving operation when the patient shows signs of sepsis. In these cases it is my custom to operate in the following way. The patient being under the influence of an anæsthetic, is placed in the lithotomy position on a table with the hips well down over the lower end. A Kelly perineum pad or ordinary oil cloth is placed under the patient, so that all fluids are directed to a pail or bucket below. The vulva and vagina are then thoroughly washed with soap and hot water, and disinfected with a hot solution of mercuric bichloride, 1 to 4,000. A Sims speculum is now introduced and held by an assistant, who also holds the right leg of the patient and the irrigating tube, while the left leg is held by a second assistant, who also administers the anæsthetic.

The anterior lip of the cervix is caught up with a tenaculum, or what is better, a tenaculum forceps, and drawn down somewhat so as to straighten the canal. The canal is now thoroughly dilated, if necessary, by an Ehlinger or Goodell dilator, and the cavity of the uterus thoroughly curretted with a sharp instrument, or else, if large pieces of tissue were left they should first be removed with a broad-bladed dressing forceps. There is very little danger of wounding the uterus unless sepsis is far advanced. Under these circumstances we must manipulate very carefully, for I have seen a curette pushed right through the fundus of the uterus into the peritoneal cavity. The horns and fundus must receive our especial attention in curetting, as these are the most difficult parts to clean.

During all this a constant stream of a solution of mercuric bichloride, 1 to 4,000, is poured upon the cervix. When the uterus has been thoroughly curetted the cavity is also irrigated with the same solution, preferably through a return catheter. The whole procedure of curetting and irrigating should be repeated to assure ourselves of the successful accomplishment of our object. Let me here say, that it must be done systematically; thus the anterior wall, the posterior wall, the right horn, the left horn, and the fundus are scraped in the order mentioned.

As the uterus has now been thoroughly cleansed the vagina is also irrigated. The fluid remaining in the vagina is mopped up with a piece of iodoform gauze, and a strip of the same material is laid into the cervical canal and to the fundus of the uterus for drainage. The tenaculum forceps can now be removed and the vagina loosely filled with gauze. If there is reason to fear hemorrhage, and there is none if we have removed the chorion and decidua thoroughly, it is well to fill the uterus tightly with gauze, which must be done with one long strip. In either case the gauze is removed in twenty-four hours. If the patient has no fever a vaginal douch of one per cent. solution of carbolic acid may be ordered. If she still has fever, the uterus should be irrigated again, and a strip of gauze again inserted into the cavity. Great care should be taken that the strip of gauze is not too wide, otherwise it will be the means of blocking up the uterine discharge.

Instead of reapplying the gauze, we may choose to irrigate the uterus every four hours with sterilized water, or a solution of mercuric bichloride of 1 to 10,000, until there is no more fever, or until we are satisfied that the germs have gone beyond the cavity and mucous membrane of the uterus.

From what has been said I would draw the following conclusions:

Since an abortion is a pathological and not a physiological condition, as is a birth at time, it must be treated on other principles than the latter. In many cases our interference becomes necessary because we deal with conditions which favor a retention of the secundines, as, for instance, a broken ovum, a displaced, a septic or otherwise diseased uterus. When we can foresee the probability of a retention we must use such efforts as will further its expulsion, provided it can be done by such means as will not produce injury to the mother.

In this condition, like in many others, to do a thing half is worse than not to do it at all

In a majority of cases a clean finger is the best instrument. However, if the whole ovum and decidua have not come away, then the forceps and the sharp curette find their places, the latter for thorough removal of the uterine decidua.

A temperature of 100° F., or above, is always a distinct indication for an immediate cleansing out of the uterus. The vulva, vagina, cervix, instruments, and hands should be made thoroughly aseptic before an operation is permitted.

In septic cases large, hot antiseptic intra-uterine injections should follow the cleansing out of the uterus, and the uterus should be drained by gauze. Let me also say that I have never seen any good come from ergot given previous to emptying the uterus.

THE USE OF THE RESORCIN TEST FOR THE DETECTION AND QUANTITATIVE ESTIMATION OF THE FREE HYDROCHLORIC ACID OF THE GASTRIC JUICE.[1]

By JULIUS FRIEDENWALD, A.B., M.D.,

BALTIMORE, MD.

CLINICAL PROFESSOR OF DISEASES OF THE STOMACH, COLLEGE OF PHYSICIANS AND SURGEONS; VISITING PHYSICIAN BAY VIEW HOSPITAL, BALTIMORE.

Since the chemical examination of the gastric secretion has assumed such importance in the diagnosis and treatment of diseases of the stomach, it is important that the simplest as well as the most reliable tests available should become better known. It is for this reason that the resorcin test of Boas is brought forward, and it will be the object of this paper to show that with it quite as reliable results can be obtained as with Günzburg's reagent, which, though more commonly employed, possesses certain disadvantages.

In 1888 Boas[2] first published the report of his reagent, consisting of:

Resorcin resub.	5
Sacch. alb.	3
Spiritus dilut.	100

and claimed for it an accuracy equal to that of Günzburg's phloroglucin vanillin[3] test. Boas's reagent, like Günzburg's, reacts only to free hydrochloric acid and never to organic acids. The reaction is carried out as follows: A few drops of the solution are heated gently in a porcelain dish with an equal quantity of gastric filtrate to complete evaporation; a red mirror is produced when free hydrochloric acid is present. Puriz,[4] A. Meyer,[5] and Leo[6] confirmed Boas's statements in regard to the accuracy of this test. Yet the reagent has never gained the popularity that it deserves. Stewart[7] almost habitually employs the phloroglucin test, but in the few instances in which he has resorted to the resorcin test the results have been equally satisfactory. In such excellent works as the new editions of Hoppe-Seyler's "Physiological Chemistry," and Von Jaksch's "Clinical Diagnosis," this test is not even mentioned, though far inferior tests are described.

My own observations with this reagent lead me to believe that it is not only quite as reliable for the detection of free hydrochloric acid as the phloroglucin test, but that it can be as well used for quantitative examinations as the latter, and perhaps with greater advantage. The accuracy of both tests is about the same. It varies, however, according to the various substances in solution with the hydrochloric acid. According to Leo,[1] .004 per cent. of hydrochloric acid in a purely watery solution may be detected by Günzburg's reagent, and .006 per cent. by the resorcin test, while in the presence of other compounds such as peptones, a much higher per cent. of hydrochloric acid may be remain undetected by either test. The following is taken from his tables:

Substances in Combination with the Watery Solution of HCl.	Percentage of HCl at which a Reaction May Still be Obtained.		
	Leo's $CaCl_3$ Method.	Resorcin.	Phloroglucin.
Water	0.002	0.006	0.004
Acid potassium phosphate. Acidity = $1^9/_{10}$ alkali	0.008	0.09	0.03
Albumen, 1 Albumen to 200 H_2O	0.002	0.08	0.05
Pepton, 2 per cent	0.002	0.16	0.16
Bread paste, 30 grammes to 200 c.c. H_2O	0.003	0.03	0.03
NaCl, one per cent.	0.003	0.0037	0.007
Grape sugar, 1 per cent	0.002	0.007	0.007
Starch paste, 2 per cent.	0.003	0.011	0.007

Inasmuch as certain substances, such as albuminous compounds, combine with a part of the hydrochloric acid and neutralize it, it was necessary for comparison in the above cases to obtain the absolute quantity of free HCl by a very accurate quantitative method, not relying on the quantity of the HCl which was added in the mixture. According to recent observations of Kossler[2] the most accurate method is the calcium carbonate test of Leo. From my own experiments concerning the limit of accuracy of phloroglucin and resorcin respectively, I have found the following results:

Substances in Combination with the Watery Solution of HCl.	Percentage of HCl at which a Reaction May Still be Obtained.		
	Leo's $CaCl_3$ Test.	Resorcin.	Phloroglucin.
Water	0.002	0.005	0.004
Acid potassium phosphate. Acidity = $1^9/_{10}$ alkali	0.009	0.007	0.004
Albumin, 1 Albumin to 200 H_2O	0.003	0.080	0.060
Pepton, 2 per cent	0.003	0.17	0.17
Bread paste, 30 grammes to 200 c.c. H_2O	0.003	0.04	0.04
NaCl, 1 per cent.	0.003	0.003	0.007
Grape sugar, 1 per cent	0.002	0.007	0.007
Starch paste, 2 per cent.	0.003	0.01	0.01

These experiments show that Boas's reagent is quite as sensitive as that of Günzburg, and that it may readily be employed for the detection of small quantities of HCl in place of the former reagent. In order to show that the resorcin test may also be utilized for quantitative purposes in the estimation of free hydrochloric acid, I have made a number of quantitative estimations of the free hydrochloric acid in a number of specimens of gastric juices, comparing the results obtained by Boas's and Günzburg's reagents with those of the more accurate method of Leo. The method employed for the resorcin estimation is similar to the one of Mintz,[3] when the estimation is made with phloroglucin.

The examination is made as follows: To ten c.c. of gastric filtrate $\frac{1}{10}$ normal, NaOH is added until a reaction can no longer be obtained by testing with Boas's reagent. If, for example, no reaction occurs after adding 1.3 c.c. decinormal NaOH, but a positive reaction was still present with only 1.2 c.c. of NaOH, then the amount of free HCl equals 1.25 calculated for 100 c.c. = 12.5, which multiplied by .00365 = .00456, the absolute per cent. of free hydrochloric acid in 100 c.c. of gastric

12	30	0.09984	0.08963	0.08728
13	41	0.13142	0.12102	0.11994
14	44	0.14227	0.13212	0.13982
15	39	0.11929	0.10812	0.10927
16	80	0.28984	0.26915	0.26203
17	59	0.18824	0.14202	0.14059
18	87	0.29981	0.27536	0.27316
19	94	0.34453	0.31247	0.32242
20	46	0.15410	0.14739	0.14227

The above table shows that while neither Günzburg nor Boas's reagents give perfectly reliable figures, results sufficiently accurate for practical purposes may be obtained with either. It yet remains to show the advantages of the resorcin test over phloroglucin.

1. Phloroglucin is quite unstable and frequently decomposes when kept for some time. Boas has recognized this fact and has modified the formula thus:

℞. Phloroglucin..... 2.0
Vanillin..... 1.0
Alcohol (eighty per cent.)..... 100.0

making it more stable.

The resorcin test may be kept for years in a dark colored bottle without undergoing decomposition or in any way losing its sensitiveness.

2. Resorcin can be had at any pharmacist's, at a trifling expense, while phloroglucin-vanillin is a comparatively expensive substance which can only be purchased from the agents of the European manufacturers. I have repeatedly used with advantage filter-paper dipped in Boas's reagent and allowed to dry to make the tests, in a manner similar to the phloroglucin test-paper of Rosenheim[1] and Boas.[2]

RECENT INVESTIGATIONS OF THE THERAPEUTIC VALUE OF ORGANIC FLUIDS, ESPECIALLY SPERMINE, IN STERILIZED SOLUTIONS.[3]

By G. E. KRIEGER, M.D.,
CHICAGO, ILL.

Some five years ago the eminent physiologist and neurologist, Brown Séquard, established the fact that the testicles of young animals contain chemical substances of high dynamo-genetic properties, and since then a great many scientific investigations have been made in order to reveal the character of those agents. The novelty of this discovery has led, at first, to very different criticisms, and the prevailing incredulity that anything could exist which would be of such a remarkable power as claimed by the author, rendered the majority of the profession unquestionable opponents of the new doctrine. The announcements of Brown-Séquard regarding injections of testicular juice on patients suffering from nervous and functionary debility, were ridiculed and, frequently without examination, Brown-Séquard's statements were flatly denied.

The efforts on the part of the inventor of this method could not prevent advantage being taken of some failures and septic accidents, probably due to a lack of asepsis in the preparation of the remedy, or during its application, and for quite a while his method seemed to be condemned as well by the public as by the profession.

However, reports of other experimenters became more and more encouraging, and what first had been looked upon as a worthless idea of an enthusiastic head, is to-day considered a discovery of the greatest therapeutic value. In fact the remarkable results obtained in some nervous affections, which previously were irremediable, have made the subject worthy of the most careful investigation.

In 1878 the German chemist, Phil. Schreiner, as described in the Annals of Chemistry and Pharmacology, found and analyzed in testicular juice a substance, called spermine, which, at first, by other chemists was declared identical with æthylenimin. Later, however, by the ingenious researches of Professor Alexander Poehl, in St. Petersburg, it was proven that spermine is an organic base with characteristic properties, and that it can be prepared from almost any organ, especially the various reproductive glands of animals.

Professor Poehl's first publication of these investigations in the St. Petersburg Medical Society, in 1890, was received with great interest by the Russian and German profession, and was soon followed by clinical experiments of noted medical men, who all agreed that spermine is the active principle of Brown-Séquard's fluid and, as a first-class stimulant, a therapeutic of unlimited value.

Such prominent physicians as Dr. Rotchinin and Professor Tarchanow in St. Petersburg, have reported a great number of cases treated successfully with spermine injections, some of which I would like to mention.

Case I.—Gentleman, fifty-three years of age, suffering from asthma, angina of the chest, and very low action of the heart, was treated with ten injections, after which all symptoms greatly improved. He could climb stairs without trouble.

Case II.—Another gentleman, sixty years of age, with short breath, pain in the chest, low pulse, recovered also very rapidly.

Case III.—A physician, seventy years of age, with paralysis of the right leg and arm, paralysis of right facial nerve, and aphasia, showed marked improvement after the second injection.

Case IV.—A man, sixty-five years of age, with diabetes (4.7 per cent. sugar), dizziness, general debility, so that he could not walk, was greatly benefited by the injections. The sugar was reduced to about two per cent.

From these and many other experiments, Dr. Rotchinin came to the following conclusions: The effect of spermine injections is that of a strong stimulant, and corresponds with those obtained by injections of Brown-Séquard's fluid. It has, however, several advantages over the latter. 1. No danger of local inflammation, as frequently observed after the use of Brown-Séquard's fluid. 2. No fever or other symptoms caused by septic elements. 3. Equality of concentration of the fluid administered.

According to Professor Tarchanow's investigations, a direct effect of spermine injections upon the blood's circulation has been observed. The action of the heart is greatly retarded, and the height of the pulse and its strength, as shown by the sphygmograph, five times, and even more, increased. These phenomena are explained by a stimulation of the nervous centres, especially the heart ganglia and the vasomotor nerves. Doctors Sicharew and Hubbenet, in the St. Petersburg Kalinkin Hospital, reported the following interesting case:

A woman, twenty-nine years of age, who had suffered for thirteen years from syphilis, was treated with blue ointment for the last six years. She became very anæmic; had at the time three ulcers on her forehead, two of which affected the bone; on the right radius periostitis gummosa, which made the movement of the hand very painful; inflammation of the right knee-joint, which was greatly swollen; periostitis on the right tibia; œdema on lower limb and foot; movability of the right knee-joint but fifteen degrees; gait very uncertain, digestion poor, frequent diarrhœa, pulse weak. In this

[1] Rosenheim: Deutsch. Med. Wochenschrift, 1891, No. 49.
[2] Boas: Diagnostik u. Therapie der Magenkrankheiten. Leipzig, 1891, Seite, 134, and Deutsche Med. Wochenschrift, 1891 S. 1080.
[3] Read before the Chicago Medical Society, March 5th.

condition the patient was put under the treatment of spermine injections. The pulse strength in the right hand and general feeling improved after the second injection. Pain of the right wrist decreased, œdema of the leg disappeared, and even the movability of the knee was restored almost to the normal condition after five injections. The pulse, being 106 before, fell to 86. The digestion became normal, and the muscular strength increased about fifty per cent. within ten days.

Another startling effect was obtained by Dr. Prochorow on a man who suffered from chronic ulcers of the lower leg, and who for several months had been treated in a hospital without success. After the second injection the ulcers commenced to heal, and within three weeks the patient was cured. From such and a great many other results, published by competent authors, one is justified in concluding that spermine has doubtless some dynamo-genetic power, and it remains to be explained what function it has as a normal factor of the organism.

We know that by the chemical change of material some products originate which are poisonous to the system, and are, therefore, by the aid of some glandular organ, discharged from the circulation. Without doubt such poisonous products must have antagonists which render them comparatively harmless during their presence in the body, and in this way prevent auto-intoxication. Therefore such agents are of substantial importance to the system. In an average healthy organism a physiological balance is observed between these two chemical opponents. If the noxious products increase, or the stimulating agents decrease, it means a lack of resistance and strength—a disposition to disease. If, on the other hand, the stimulating agents are predominating, it means vigor and health. If such is the case, why should it not be possible, by the introduction of such stimulating agents into the system with which the organism defends itself, to overcome the lack of resistance brought on by any cause which is detrimental to health?

The difficulty, of course, will be to prove that the substance artificially obtained is identical, or at least similar, to those prepared in the organism. It is not very long ago that Charcot and Leyden made the discovery that in certain diseases on the surface of the lungs, spleen, and other organs, small crystals appeared, the significance of which was not understood until later examinations revealed their chemical composition. The crystals found, especially in asthmatic persons, and known as Charcot-Leyden crystals, are nothing else but phosphate of spermine. These crystals have also been found in the discharges of persons with typhoid, consumption, cholera; in leucæmia and other diseases. By their discharge from the circulation the organism of such patients evidently lost a quantity of spermine, and therefore such stimulation to the nervous centres as would be necessary to check the power of weakening elements. The evidence of the chemical relation between these crystals and spermine led to the treatment of asthmatic persons with injections of spermine, and, as anticipated, generally with good, sometimes with excellent, success. Lately I treated a case which greatly improved after ten injections. There can, therefore, be no doubt that spermine has a stimulating effect upon those centres to which the cause for asthmatic attacks is attributed.

Not less remarkable results were obtained in cases of neurasthenia and anæmia. Professor Sicharew[1] reported several cases of severe neurasthenia with agrophobia and claustrophobia—those strange phenomena in persons who become dizzy and nervous while being on a wide field, and who feel frightened when inclosed in a room—in which cases these symptoms disappeared after injections of spermine. In another case of severe anæmia the person referred to had nine or ten hysteric spells daily, suffered from insomnia and great weakness; perfect cure was obtained. An old gentleman, sixty-three years of age, with general debility, apathetic to his surroundings, unable to follow a conversation or to move about, improved so much that he could walk alone and grew stronger physically and mentally.

A special effect seemed to be obtained by spermine upon the spinal plexus; quite a number of cases of locomotor ataxia have been reported in which either a perfect and lasting cure, or at least a great improvement, was the result of spermine injections.

A patient of Dr. Sicharew,[1] fifty-three years old, with myelitis of the lumbar part of the spinal cord, causing paresis of the lower extremities, incontinence of urine, constipation, and loss of his sexual energy, recovered after nine injections.

To quote from the statistics of 182 cases recently published in the *Berlin Klin. Woch.*, an exceedingly good effect was secured in 52 cases of neurasthenia. Only 2 did not show an improvement. From 14 cases of locomotor ataxia, 12; from 23 with other nervous troubles, 21 improved. Also 57 with general debility, 9 with scorbutus, 14 with consumption, have shown a favorable effect.

Very much interested by all these reports, I have made this subject a special study for over a year, and have investigated the therapeutic value of spermine on my patients. To have sufficient material without depending on the Russian drug, which is very expensive—about two dollars a dose—I have experimented for fourteen months in my laboratory, fitted up for the purpose of securing an equally effective substance, and finally succeeded in getting the specimen I wished to obtain. I also, by the courtesy of Professor Poehl, in St. Petersburg, with whom I communicated, got into possession of a quantity of his preparation, which I used to compare the effects obtained from his spermine and the one prepared by myself. The result was equally favorable in cases selected for this treatment. I have since been supported in the investigation of the therapeutic value of my product by other gentlemen, who are present to night, and wish to demonstrate the result of some cases which have been treated during the last three months.

Case I.—Mrs. H——, thirty-nine years of age, five feet three inches high, very stout, weighs one hundred and ninety pounds. Has always menstruated regularly, but generally with great pain. Was married sixteen years ago, has two children. Since the last two years she has suffered from abdominal and lumbar neuralgia, for which she was repeatedly treated, without success. The abdominal organs are in a normal condition. Patient had also frequent palpitations and neuralgic pain of the heart, was very irritable, nervous, and easily frightened; could not sleep well, and complained of frequent headaches. In this condition she came to me three weeks ago. Taking the symptoms described as caused by general neurasthenia, I advised her to be treated by spermine injections. After one injection of a ten grain spermine solution she felt easier and quieted. She received one dose daily for nine days, during which she evidently improved. On the fifth day she stated that all her ailments had left her, and her husband claimed that she had changed remarkably. It is now twenty days since the first injection was given, and for the last two weeks the patient has felt perfectly well.

Case II.—Another treatment I began on this gentleman, who is seventy years of age, and, as you see, in apparently very good condition. He was never sick up to his sixty-fifth year; in 1889 he had an attack of inflammatory rheumatism of the joints; in 1890 was treated for gravel in the bladder, which disappeared after the use of lithia water, and since the last four years complains of neuralgic pain in the head and lumbar regions, heaviness in the legs, general weakness, and insomnia. I attributed these symptoms, naturally, to his advanced age, and thought spermine would refresh him. The injections, given as usual in the back, affected him in a peculiar way. He claimed to feel them all through his chest as a warm, stimulating agent, and soon assured me

[1] Berl. Klin. Woch., No. 40, 1891.

[1] Petersburg Med. Ges., February 26, 1891.

of their good effect upon his general health. The neuralgic pain in the back, and weakness in the limbs disappeared, his sleep and strength improved, the headache became less, and taking all together, he says he feels twenty five years younger.

Case III.—Of special interest, I think, is another case which I would like to present, and about which I would be glad to hear the opinion of some gentlemen who make diseases of the nervous system a specialty. From the most apparent symptoms I may call it a case of spinal sclerosis, but it seems to me that there are also other atrophic processes, possibly of a cerebral nature. As far as I could learn, the history is as follows: The patient, a man, fifty seven years of age, five feet ten inches tall, weighed two hundred and thirty pounds, was always in good health up till March, 1893. He did not indulge in alcoholic drinks, never suffered from syphilis, but was a heavy smoker. In March, 1893, he complained of slowly growing weakness in the right, later in the left, leg. His limbs were as if burdened by weights. Then a constant dizziness in the head set in. He was treated for apoplexy, with no effect. The weakness of his legs progressed until they would not carry him any more. His dizziness also grew worse; he became irritable, nervous; could not sleep, but had fair appetite and digestion. He was under the treatment of several physicians, the last of whom supposing the disease was of syphilitic origin, put him under inunctions and iodide of potash. The patient lost about thirty pounds. His condition, however, did not improve, and when I saw him first, on February 6th, I found the following state:

A man, strongly built, sat in an arm-chair, his features showing signs of despair, his eyes were clear but unsteady; he was unable to rise, or even to raise his legs, but could move his arms pretty freely. His grasp was weak, and the movement of the hand and arm somewhat inco-ordinated; for instance, when he wanted to reach for something he failed to strike it. The fingers spread apart, trembled; on the finger-tips and under the sole he had a numb and prickling sensation. He was free of pain, but complained of a heavy and dizzy feeling in his head. Reflex of the pupils was good. When lifted from the chair he could stand, his legs spread apart about eighteen inches. With closed legs he tumbled. He also became very uncertain with his eyes closed. Supported on either side he tried to walk; the legs were moved with difficulty and inco-ordinately; the feet were swung forward and set down with force, as though the patient was uncertain in reaching the floor; brought back to his chair he felt very tired. The sensibility of the skin and reflex of the patella were but little disturbed. The functions of the bladder and rectum have lately become weak, the patient has frequent pressure to pass urine, the examination of which showed nothing abnormal. Examination of the eyes showed atrophy of the left optic nerve, otherwise no characteristic signs. For the last two months he has been unable to lie down, was obliged to sit up all night, and compelled to sleep in his chair. He also complained of an almost constant ringing noise in his ears.

In this condition I subjected him to a treatment of spermine injections, with the following effect: After five injections he could easily rise and stand with his heels and toes closed, without tumbling. He got fifteen injections altogether and is now able to walk fairly well, and even to climb stairs with some effort. He feels a great deal stronger, can lie down and sleep sometimes all night. During this treatment I avoided any other therapeutic aid. The only symptom that still annoys him is the dizziness in the head, to which he pays so much more attention after being relieved from the confinement to his chair.

On these, and quite a number of other cases, I have studied the effect of spermine injections, and have had in some of them surprisingly good results, while the rest were more or less favorably affected. One feature I would like to emphasize; spermine seems to be a direct antidote against the bad effects of anæsthetics, probably due to the stimulation of the heart action. In 1891 the Russian surgeon, Weljaminoff, and recently I, myself, have observed that patients who received one spermine injection shortly before an operation was to be performed, had a splendid narcosis, and no nausea or any other bad effect after they awoke. In order to ascertain if their condition was really obtained by the action of spermine, I have experimented in the Chicago Hospital on a patient who had to take ether several times. He was a man of thirty-nine years of age, upon whom I was going to perform Lange's or Whitehead's operation for hæmorrhoids. He received a fifteen-grain spermine solution shortly before the anæsthetic was given. He was one hour and a half under the influence of ether; had a splendid narcosis, and when he awoke felt perfectly well. Eight days later I gave him again some ether to remove the stitches without using spermine. He then was only fifteen minutes under the influence of the narcotic, but it took him all day to overcome the nausea and bad feeling with which he awoke. It is, of course, a question in how many cases such a favorable effect will be obtained, and I do not doubt that frequently the injections may fail to act as desired, but still I think it may be worth trying.

Before I conclude I wish to say a few words about the chemical and physiological properties of spermine. Spermine, according to the analysis of Phil. Schreiner,[1] is a substance with the chemical formula $C_5H_{14}N$. Like other bases it forms salts when in contact with acids or metals. Some of these salts are long prismatic crystals which, though prepared by chemicals, retain the physiological properties that spermine possesses. Such crystals I have photographed from microscopical specimens; the specimens were obtained from preparations from different organs: No. 1, from testicles of a young bull; No. 2, from ovaries of a young cow. Nos. 3 and 4, prepared in a different way, are not as pure as the first ones; No. 3 is made from a small quantity of genuine Brown-Séquard's fluid; No. 4, from an extract of pancreas. Regarding the chemical composition, spermine belongs to the group of the imins, and has at first by some chemists been taken for æthylenimin, which has the formula C_2H_5NH; that is, the same elements, but in another group. By the investigations of Professor Poehl this opinion has been proved to be a mistake. He found that spermine is a base *per se*, with certain characteristic properties different from those substances with equal elements. Some of its reactions are: 1. With chloride of gold it forms a yellow precipitate, which later changes into flat crystals. 2. With chloride of platina it forms a crystalline precipitate. 3. With sodium of tungstate it gives a cloudy precipitate soluble in alkalies, insoluble in acids. The most characteristic property is a smell like human sperma, if spermine is brought in contact with chloride of gold and metallic magnesia. I have here a sample of such combination, and you may convince yourselves that my preparation really contains spermine. It was for these reactions that I worked over a year and made many thousands of experiments; after which I learned to understand why such a noted firm as Merck & Co. pronounced, in the *Pharmaceutical Zeitschrift* for Russia in 1890, that they did not succeed in preparing this valuable substance. The same statement has been made by other chemical firms; and I think this is the reason why, up to date, spermine has not appeared in the list of our modern therapeutics. Professor Poehl himself said, in the *Berlin Klin. Woch.*, 1891, "The conditions by which spermine crystals may be obtained from solutions which contain spermine are sometimes very difficult to determine;" and I also have found that, when I repeated the same process on the same preparation, I would at times not obtain the same crystallization as previously found.

Regarding the physiological action of spermine, chemical and physiological experiments have revealed the fact that the stimulation and otherwise beneficial effects from spermine injections are very natural. Since it is known

[1] Ann. Chem. Pharm., 1878, 194.

that spermine is not only an important factor of the reproductive glands in the male as in the female organism, but also exists in the thyroid gland, the thymus, pancreas, spleen, and other organs, it has become evident that spermine is a normal substance circulating in the blood, which has to and does accomplish a certain task in the economy of life. Medical science was greatly mistaken when it was believed that some organs, as the spleen, subrenal glands, and others, were of no use in a biological respect, and could just as well be parted with.. By the bad effect obtained from the extirpation of the thyroid gland we have been convinced that in this, as in other glands, a substance is produced which is absolutely necessary for our system, and which is probably similar to spermine; and so I believe that an important function of those organs is the production of spermine. The fact that male animals deprived of their sexual glands in their early days cannot compete in strength with their brothers, who are still in possession of these vital organs, has led to the interesting experiment on dogs to inject spermine as a substitute. Of four young dogs, all brothers, two treated this way, after being castrated, grew twice as large and strong as the other two. The incorporation of such substances as are produced in our glands into the blood is therefore a very natural support of a physiological process.

The manner in which spermine acts upon the organism has been carefully studied by Tarchanoff, Poehl, and others, who are of the opinion that the stimulative effect of spermine is due to its great oxidizing power. This theory is supported by the following facts:

1. Metallic magnesia in solution of the chloride of a metal changes into oxide of magnesia by the influence of spermine in very small quantity.

2. The blood, if influenced by chemical agents which diminish its oxidizing power, as chloroform, oxydul of nitrogen, strychnia, urea, can be brought to its normal condition by the support of spermine. This explains the favorable effects of spermine injections during and after the narcosis.

3. A direct test for the oxidizing power of spermine was obtained by quantitative examinations of the urine before and after spermine injections, which showed a stronger oxidation of the albuminoids after the injections.

From these facts it does not seem strange that in diseases which diminish the oxidizing energy of the blood and nervous system, as in neurasthenic, anæmic, cachectic persons, spermine injections have a very favorable effect. The same observation has been made in auto-intoxications, that is, in diseases where the products of the regressive albumin metamorphosis accumulate in the organs.

A very important factor for the effect of spermine is the alkalinity of the blood. As a rule, in all the named diseases, as well as in acute fevers, as typhoid, scarlet, pneumonia, erysipelas, the blood possesses a higher degree of acidity, in which spermine becomes insoluble, and therefore inactive. If the acidity is neutralized, as, for instance, in diabetes, by the use of Carlsbad salts, the spermine gets its activity again, and the improved oxidation causes the disappearance of sugar in the urine. The same result has been obtained without alkalizing the blood by artificial introduction of spermine. As the latter is a normal substance of the organism its application is an imitation and support of nature, and therefore entirely harmless if used under certain precautions.

It is different from Brown-Séquard's fluid, inasmuch as the latter contains a number of substances, as kreatin, kreatinin, hypoxanthin, lecithin, guanin, nuclein, and so on, which do not benefit and may hurt. Furthermore, as it is known that the organs from which the emulsion known as Brown-Séquard's fluid is obtained often contain the germs of disease and other products, the toxines cannot be eliminated by the way the fluid is prepared, and is, in a strict sense of asepsis, not a safe method. The injections are sometimes followed by an abscess, an accident that has recently occurred in this city in the hands of a physician of very high standing, a complication I have never seen reported nor observed after spermine injections.

The isolation of the active principle is therefore of vital importance, and besides has the advantage that the dose can be regulated, which is impossible in Brown-Séquard's fluid, because no one can tell how much spermine it contains. The solution I use is equal to two per cent., and always bacteriologically tested before being put in flasks, so I am sure it will be aseptic; and although I do not claim that it will have the desired effect in every case, on the contrary am fully prepared to see occasionally a failure, I think the subject is worth trying.

As far as the technique is concerned, I have found it advisable to use a series of from ten to fifteen injections, one a day, commencing with small doses, about five to ten minims, and gradually increasing the dose to twenty minims. The number of doses required is, however, a matter of personal judgment, and sometimes two or three injections are sufficient to secure a remarkable effect.

In order to keep this solution perfectly aseptic I have put up single doses in separate flasks, as the one demonstrated. They are opened by hitting against the neck, which will break at the mark. The fluid is then taken out with a hypodermic needle, which should always be thoroughly cleansed before and after using. The most aseptic instrument for the purpose is a syringe with a piston of asbestos. It seems practical to inject very slowly after the skin has been thoroughly sterilized. With these precautions, I have never had any trouble, except slight local irritation.

In conclusion, I wish to *résumé* the different effects obtained by spermine injections in various diseases treated by other physicians and myself:

1. The action of the heart is stimulated. (Drs. Hubbenet, Sicharew, Rotschinin, Nicholsky, Philipps, Tarchanow, Krieger.)

2 The respiration becomes easier, more regular, and less frequent. (Drs. Nastjukoff, Rotschinin, Injaseffsky.)

3. The general feeling improves. (Drs. Stange, Kissel, Rotschinin, Hubbenet, Ritter, Krieger.)

4. The muscular strength increases. (Drs. Tarchanow, Sicharew, Rotschinin.)

5. Sleep and appetite improve. (Drs. Nicholsky, Wikterow, Philipps, Krieger.)

6. Œdema, due to lack of power in the arterial system, disappears. (Drs. Hubbenet, Sicharew, Rotschinin.)

7. Sugar in the urine decreases. (Drs. Tarchanow, Poehl.)

8. Ataxy of muscles, especially caused by spinal troubles, decreases. (Drs. Sawitsch, Wiktorow, Hubbenet, Krieger.)

9. Neuralgia, especially of lumbar origin, disappears. (Drs. Rotschinin, Ritter, Krieger.)

10. The sexual functions are stimulated. (Drs. Sicharew, Hubbenet, Tarchanow, Krieger.) This may be taken as a result of general improvement, but in my estimation should not be considered a specific effect.

11. The functions of the bladder and kidneys, also of the intestinal tract, improve.

12. Local reactions are either of a slight and harmless nature or do not happen at all.

Although such favorable results have been recorded in hundreds of cases, I do not wish to say that they will always be obtained, and we have to be prepared in some cases to miss the desired effect. The exceptions, however, do not speak against the method as a whole, but rather, as the Latin phrase says: "*Exceptio firmat regulum.*"

1003 Columbus Memorial Building.

Professor Gussenbauer, of Prague, has been elected President of the German Surgical Congress for 1895.

Progress of Medical Science.

The Treatment of Pelvic Abscess.—According to the Berlin correspondent of the *Medical Press*, Dr. L. Landau recently gave an address on this subject. He said that with the perfection of gynecological technique gynecological diagnosis, as regarded the individual operations, had not advanced with great pace. For, first of all, diseases had to be discovered for given operations; and in the second place a large series of diseases of unequal importance had been grouped together under collective names, and had been frequently submitted without discrimination to a single operative treatment. This was especially the case as regarded pelvic suppurations, where the usual diagnoses—pelvic abscess, pelvic suppuration, adnexitis—were used without distinction for simple non-suppurative inflammation in the tubes or ovaries, or peritoneum, as well as for multiple extra- and intra-peritoneal abscesses. He had above all endeavored to fix an exact pathologico anatomical basis and a rational division of pelvic suppurations. He distinguished in the large group of extra- or intra-peritoneal abscesses, the abscesses in pre-formed spaces (pyometra, pyosalpinx) and those not in pre formed spaces (abscesses in paravaginal, paramitral tissues, in subperitoneal pelvic tissues, and in the connective tissue of the abdominal walls), with intermedial position of ovarian abscess. The abscesses might be single or multiple, or in the most varied combinations. The cause was always an infection. Among these was the gonorrhœal, the puerperal, and, "last not least," the infection of medical assistance (from the sound, curette, intra-uterine injections, caustics, operations on the cervix, and vagina). These abscesses terminated very differently. Inspissation, absorption, and spontaneous cure might take place, or perforation into the neighboring organs, and spontaneous cure or perforation into the peritoneum with circumscribed or general fatal peritonitis and pyæmia. Occasionally death took place from amyloid disease. The old motto, *Ubi pus ubi evacua*, was to be firmly held to, and this was to be carried out wherever the pus was accessible by simple, sparing, conservative methods. Incision came first under consideration. This was before all indicated with solitary uncomplicated pus cavities, whether lying within or without the peritoneum, or whether done from the vagina or abdominal wall. It should not be done through the rectum, as he had observed that healing was difficult. He made abdominal incision either above or below Poupart's ligament, at one sitting where dulness was complete, at two sittings if intestine apparently intervened. The first incision as for ligature of the iliac artery, pushing up the peritoneum, packing with iodoform gauze, etc. A means of distinguishing abscesses from induration, exudation, and fibroids, indispensable in many cases, was exploratory puncture. It at the same time formed an important preliminary to the incision. When operating from the vagina it was always done at one sitting. Solitary abscesses in the pelvis of whatever kinds were to be treated in this way, even pyosalpinx when the pus was in one cavity.

Considering the good results obtained by simple incision, the attempt was justifiable to try it in multiple abscesses (double one cavities, pyosalpinx, etc.). The causes of recurrence might be in fineness of the walls of the abscess, in adhesive fixations preventing the walls of the abscess falling in or otherwise. For cases in which simple incision would evidently be insufficient, as in multilocular pyosalpinx with or without perforation into the pelvis or abdomen, bladder or multiple perimetric and perisalpingial abscesses, a variety of other procedures had been practised, of which he would only mention historically the little-promising sacral and para-sacral incision. Here laparotomy was the operation usually practised, with removal of the abscess walls and its contents. He had treated one hundred and forty-one cases of inflammatory and suppurative tubal disease by laparotomy, with a mortality of 2.8 per cent. This undeniable good result coincided with those of other operators (Chrobak, Schanta, Zweifel, and others). But, unfortunately, as observation had shown, the permanent results were not equally favorable. Complete cures took place in only from sixty to eighty per cent. (Chrobak, Schanta, Landau). The reasons for this were threefold: 1. In the disadvantages of laparotomy itself (abdominal hernia, adhesion of intestine and omentum to wound and to one another, etc.). 2. In recurrences of inflammation and suppuration through impossibility of removing all excitors of inflammation. 3. In the purulent nature of the disease.

Then arose the question, how could these disadvantages be guarded against? The first step thereto attended by success was made in France; in the first place by Péan, and after him by Ségond, Doyen, Richelot. The uterus was removed, and excellent results had been reported from this method of treatment. But want of exact pathological data made it difficult to determine the value of such a mutilating operation. Spurred on by the statements of Péan and Ségond, and instructed by a number of vaginal extirpations of uterus performed since 1881, he had treated, since May, 1893, twenty-six cases by the French vaginal procedure. He had, however, deviated from this method in two essential points, and had extended the limits of the operation as laid down by these authors. He had never contented himself with removing the uterus and leaving behind the adnexa, but had always removed the diseased parts. He had adhered to this principle so firmly that when it was impossible to root out all the disease per vaginam, he had also opened the abdomen from above. He had, moreover, operated in this way on women when there was not only a simple double inflammatory disease, but in cases of complicated pelvic abscess. His definition of complicated pelvic abscess was one when, independent of double pyosalpinx or ovarian abscesses, there were present perisalpingial, periphoritic, or multiple isolated intra- or extra peritoneal abscesses; thus perisalpingitis purulenta, perimetritis purulenta, pyocele uterina, retro-peritoneal suppurations. Such were cases that could neither be treated by simple incision from the vagina nor through the abdominal walls by laparotomy, as it would either be impossible or would be too dangerous to carry out the operation. In all these cases there were multiple collections of thick, yellow, or green stinking, decomposing, or creamy pus. In some cases there was fistulous communication into the bladder or rectum, most of the cases were disabled from long-standing disease, and six had been repeatedly treated in other hospitals. In a large number operation had been already performed with temporary success (puncture, incision, resection, laparotomy). In some cases the attachments to the rectum, and especially the sigmoid flexure and to the bladder, were so firm that in carrying out the principle of removing all diseased parts the walls of these organs were torn. In two cases of vesical fistula originating in this way he had operated there and then, once from the vagina and once from the abdomen. In two ruptures of the sigmoid flexure he had performed circular resection. The whole of the twenty-eight cases were cured by the operation.

The Treatment of Typhoid Fever in Children.—At the onset of the attack, when the diagnosis is still uncertain and resembles in some respects the fever due to gastric disorder, it is well to administer small doses of calomel with a little milk-sugar, and to give a rectal injection of an infusion of chamomile in boiled water, with four per cent. of boric acid, morning and night (*Therapeutic Gazette*). Internally, to give from a coffee- to a dessert-spoonful every two hours of the following prescription:

℞. Benzonaphthol..... gr. xiij–xxx.
Syrup of peppermint..... ℥ j.
Syrup..... ℥ iv.

In the way of nourishment the patient may be given

every two hours a very small cup of milk, to which may be added as a stimulant a little coffee, tea, cognac, or a very slight flavoring with vanilla or chocolate. In cases where the diagnosis is thoroughly assured after the calomel has acted, it is well to prescribe citrate of magnesium to move the bowels and large rectal injections morning and night of a borated solution already named; or,

℞. Naphthol ..... gr. iij.
Boiled water ..... Oij.
To be used in four equal quantities.

Internally, an antiseptic dose, composed as follows, is useful:

℞. Benzonaphthol ..... gr. xv.–xxx.
Salicylate of magnesium. ..... ʒ ss.–ʒ j.
Syrup of peppermint ..... ʒ vj.
Simple syrup ..... ʒ iv.

If there is a bitter taste, it is well to replace the salicylate of magnesium by the salicylate of bismuth. Of this mixture give a teaspoonful every two hours, and morning and night administer a capsule or cachet containing two to four grains of the hydrochlorate of quinine, or else give the same dose by injection or suppositories. If the headache is severe, replace the quinine by antipyrin; spongings with tepid water may be resorted to, and care should be taken, by the use of a boric-acid mouth-wash, to keep the mouth clean. If the fever is of great intensity, the same treatment, with the addition of constant spongings with cooler water, is to be followed, and should the nervous disturbance be very great, small doses of coffee or of chloral may be used, but antypyrin is not to be employed. In grave cases the baths are given even more frequently, as often as is necessary to keep the temperature down. For the nervous agitation the following mixture may be prescribed:

℞. Hydrate of chloral ..... gr. vj.–xv.
Tincture of musk ..... gtt. xx.–xl.
Syrup of orange ..... ʒ j.
Water ..... ʒ ij.

Cold compresses are to be applied to the head, if there is delirium. In cases showing marked adynamia the cold should be applied to the head and the following mixture given:

℞. Hoffmann's anodyne ..... gtt. x.–xv.
Malaga wine ..... ʒ j.
Syrup of mint ..... ʒ j.
Water ..... ʒ iij.
A teaspoonful to a tablespoonful every hour.

In cases of typhoid fever in which there seems to be great cardiac depression, the pulse being feeble and showing evidences of collapse, it is well to use the following injection hypodermically morning and night:

℞. Caffeine ..... gr. xxx.
Benzoate of sodium ..... gr. xlv.
Distilled water, enough to make ..... ʒ j.
Ten to twenty minims of this may be used.

Where complications such as bronchitis, broncho-pneumonia, etc., arise, the same treatment is to be continued as that just given, but the cold spongings are to be stopped and a cotton jacket is to be applied to the chest. Morning and night a mustard sinapism should be applied to the chest and the stimulating treatment already indicated employed.

During the period of convalescence the baths are diminished as the temperature approaches the normal. Soups, broths, and thoroughly softly cooked meats and pulpy vegetables are allowed, and the following tonic mixture given in the dose of a dessert-spoonful three times a day:

℞. Tincture of gentian,
Tincture of cinchona, of each ..... ʒ v.
Fluid extract of kola ..... ♏ lxxv.

Champagne also is sometimes useful if it agrees with the patient. Should hemorrhage from the intestine complicate the case, absolute rest, with local application of cold, is to be resorted to. Small doses of opium may be administered by the mouth, and every two or three hours two or three drops of perchloride of iron are to be employed. Ice-compresses should be applied over the belly. Where there is danger of sloughs and abscesses it is well to wash the part with a four-per-cent. solution of boric acid, and afterward apply iodoform or salol. Abscesses, of course, should be opened, drained, and irrigated with mild antiseptic solutions. For the prophylaxis of typhoid fever the discharges of the patient should be received in a five-per-cent. solution of sulphate of copper or in a 1 to 1,000 solution of bichloride of mercury. The milk which is taken by the patient should be carefully sterilized, and after the case recovers careful disinfection of all the vessels used by the patient should be carried out.

The Value of Boiled Milk as an Article of Diet.—Every practitioner of medicine knows that in the treatment of certain cases of diarrhœa, where an absolute milk diet is required, better results follow the use of boiled milk than of raw milk, and for this reason it has become a popular idea among the laity and members of the profession that cooked milk is the more digestible. However this may be in clinical experience, it is certain that experimental research does not justify this conclusion. Ten years ago the late Dr. Randolph, of Philadelphia, made an interesting series of experiments to determine this point. A number of men in perfect health were given raw milk to drink; an equal number, equally healthy, were given a similar quantity of boiled milk. An equal time after the ingestion of the liquid a hypodermic injection of apomorphine was administered to each, and a careful examination made of the vomited matters to determine how far the process of digestion had proceeded. In every instance it was found that the raw milk was more digested than the cooked, and as Randolph graphically expressed it, "We obtained proof that in making milk, nature made that compound most easy of digestion."

The experiments of Crolas, on the other hand, seem to point to a different result, for he believes as a result of his studies that boiling has no action whatever on the casein or lactose, and removes from the liquid a small quantity of butter, which is entangled with the film of albumin which forms on the surface of the milk. He also thinks that boiling increases the quantity of the free soluble phosphates, and concludes, in opposition to the studies of Randolph, that boiled milk is equivalent, if not superior, to raw milk.

The correct solution of the problem probably lies in the class of cases to which the milk is administered. There is no doubt whatever that raw milk is more digestible than boiled to the healthy individual, and it is an undeniable fact that boiled milk is far more constipating, and that an attempt to place a patient upon a diet of boiled milk would more certainly tend to disorder digestion and assimilation than a similar attempt with the raw article. In Bright's disease, diabetes, and similar conditions in which a milk diet is desirable, we may therefore conclude that raw milk is the liquid to be employed, whereas, in cases of diarrhœa, the boiled milk is by far the best preparation. We have already pointed out in earlier leading articles that both raw and boiled milk have their digestibility very much increased by being somewhat diluted with any sparkling water, or by the addition of a sufficient quantity of salt to give a distinct flavor.—*Therapeutic Gazette.*

Treatment of Vaginismus.—In a paper read before the British Medical Association, Dr. T. More Madden held that vaginismus is ordinarily of constitutional or neurasthenic origin, and is frequently associated with a morbid condition of the pudic nerves. Hence he relies chiefly on constitutional treatment in combination with local nerve-stretching. To effect this he recommends forcible dilation, under ether, of the vagina, so as to thoroughly stretch, or even partially rupture, the fibres of the affected pudic nerve and its terminal branches. If this treatment be adopted, Dr. Madden believes that it will seldom be found necessary to resort to operative treatment for the cure of dyspareunia caused by vaginismus.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, October 6, 1894.

BRIGHT'S DISEASE AND ITS INSANITIES.

BRIGHT'S disease in its various forms is so common and dreaded a malady that all the phenomena connected with it are justly objects of importance to every practitioner. One particular phase of the Brightique state is mental disturbance. Concerning this, much has been written of late, so much, indeed, that the matter has become rather beclouded than otherwise by the learned, scholastic, and not very accordant contributions of alienists. One writer has placed uræmic poisoning among the frequent causes of insanity and the starting-point of nearly all cases of melancholia. Dr. Savage, on the other hand, as the result of several hundred examinations of the urine of the insane, declares that he has rarely found albuminuria.

There can be no doubt of the importance of the arterio renal sclerosis associated with Bright's disease in causing many of the insanities of middle and late life. The psychical symptoms which develop in connection with kidney disease are usually grouped in three classes. There is first the acute delirium which sometimes is associated with acute nephritis due to some infection. The uræmic poisoning here, if it exists, is only one factor, and the delirium itself is classed as a "non-vesanic" insanity, *i.e.*, it is not insanity at all in the technical sense.

Uræmic or Brightic insanity proper occurs only under two forms. In the one the patient has no insane heredity or tendency, but is perhaps of neurotic temperament. The poisons of the uræmic state in such an individual affect the nutrition of the brain, there is some arterial spasm or thickening of the walls, and the total amount of blood sent to the brain is inadequate. The patient suffers from a mild and quiet mania which is allied to dementia. He improves or gets worse with the course of the albuminuria, and if that disappears he may get entirely well. In the other cases the patient is a person predisposed to insanity, and the renal trouble acts simply as an exciting cause. The form of mental trouble in these cases is not much affected by the albuminuria. It may be a monomania, a melancholia, or some more excitable state.

When the practitioner notes the appearance of mental symptoms in a case of chronic Bright's disease, it is of the first importance that he make himself familiar with the history and diathesis of his patient. If the insanity is of the first type and due mainly to the renal trouble, treatment directed to this will often relieve and even cure the patient. He can be treated at his home. In the second class of cases the outlook is more uncertain; serious outbursts may occur, and restraint in some institution is indicated.

THE COMPOSITE PHYSICIAN.

PROFESSOR H. P. BOWDITCH has published in *McClure's Magazine* two series of pictures of twelve Boston physicians with their composite photographs. The second series and its composite represents the same gentlemen five years later. Dr. Bowditch's article is a contribution to science rather than to the beautiful. We say this after a really unbiassed and sympathetic search for a handsome man among the twelve esteemed and eminent confrères. We do not find, to be sure, any striking type of the opposite kind; there are no features that are absolutely Socratic in their curves or their asymmetry. But it is evident that Boston's twelve have not won success through the meretricious aid of personal loveliness.

There is no Antinous there; no Apollo, or any of the quality that used so seductively to "hang upon the cheek of night" in the Cleopatra days. However, classic authority says it is a nuisance to be too beautiful—"miseria nimis pulchrum esse hominem." And we note that the individual Boston physician is interesting, and his composite a most agreeable-looking gentleman. The age of the composite is about forty. The hair is thin, and the parting is nearer the right ear than urban fashion dictates. He wears a heavy mustache with the ghostly suggestion of an imperial. The nose turns up a trifle and reveals well-defined nostrils, suggesting an absence of Semitic and a touch of Celtic blood. There is a deep naso-oval fold indicating a consciousness of life's burden and responsibilities. The forehead is high and broad as in all types of successful men except the artist. The eyes are those of a composite, bright and kindly. The collars and ties date back into the last decade.

Altogether the Boston composite is a good type of a man, not resembling in the least any of the individuals of which it is made.

TUBERCULOSIS AND BUTTER.

IT is hard to get away from the malign influence of the cow. Such at least is the case if we may trust the investigations of bacteriologists and sanitarians. The statistics of slaughtered animals in Prussia, Hanover, Switzerland, and other European countries show that from two to twelve per cent. of the cattle are tuberculous, and though their flesh is not often dangerous, yet the milk must in most cases have been so. We can guard against tuberculous milk by sterilization, but now danger is threatened us from the butter. Several years ago Heim showed that butter from tuberculous milk contained bacilli and could produce infection. Bang (*Deut. Zeitsch. f. Thiermed.*, vii., p. 5) reached similar conclusions.

Professor Roth, of Zurich, has, however, recently made experiments of more striking significance (*Correspond. bl. f. Schweit. Aertz.*). He went into the markets and purchased butter from twenty different sources representing different cantons of Switzerland. He then inoculated guinea pigs with this butter. In

eighteen series of experiments the results were negative, but in two the inoculations were followed by tuberculosis. In other words, ten per cent. of the butter of the Swiss markets contained tubercle bacilli.

Quite independently of Roth, Dr. Brusaferro, of Turin, made experiments with the butter of the Italian markets. In nine tubs he produced infection once, which gives about the same proportion as Roth's.

It is not to be supposed that ten per cent. of market butter is necessarily dangerous, for in many instances the number of bacilli is small and quite unable to cope with the juices of the stomach. Still, infected butter is not safe to the predisposed, and the fact of its existence in Europe at least should be borne in mind. What makes the matter additionally serious is the fact that there is not, so far as we know, any practical way of sterilizing butter.

AN ANTI-OPIATE SOCIETY.

An Anti-opiate Society has been organized in this city, and announces that its objects are to use such means as may be considered best to prevent the unnatural use and the abuse of opium and its preparations, and of cocaine, chloral, etc.

We are told that there are now in the United States one and a half million men and women who habitually use opium in some of its forms. Twenty years ago there were less than three hundred thousand opium users in the same territory. The extent to which this vice is increasing may be inferred from these figures: in the city of Chicago, 25,000 persons are addicted to the habit; in New York City, over 50,000; and in St. Louis about 20,000 are slaves of this merciless tyrant.

It is added that "There are other thousands of habitual users of morphine who would never have touched it had they not been ignorant of its powers, influence, and effects. It is such ignorant ones that the Anti-opiate Society is trying to reach with informa ion regarding the nature of the insidious drug, and with warnings to the young and unwary against a vice so delusive and so dangerous, trying to reach them before they have become hopelessly degraded by its influence."

The increase and the prosperity of the various "anti" societies is one of the evidences of the development of altruism as well as of intelligence in modern times. Some of these societies, unfortunately, show more altruism than intelligence. We trust that the present organization will not be of such kind. There is indeed little room for exaggeration in describing the evils of the opium habit; and there is, we fear, among some physicians, though they are vastly in the minority, a disposition to be careless in prescribing the narcotics. Perhaps the one thing which general practitioners least realize is the quickness with which a tenacious habit is formed. The constant use of opium for a few weeks, for example, will as a rule establish a habit hard to break.

On the other hand, we regret to see the new society starting out with exaggerated and unsupported statements of the prevalence of the opium habit. Fifty thousand opium users in New York City means that one out of every twenty adult persons is a habitué. This is too absurdly untrue to need contradiction. Our advice to the new society is to re write its circular, and afterward to be earnest but also honest.

News of the Week.

Death of Dr. Francis G. Mosher, of Coeymans, N. Y.—Dr. Francis G. Mosher died September 22d, at his residence, Coeymans, N. Y., of cancer, aged seventy-one. He was a great sufferer for many months previous to his death, but continued his work up to within a short time of his death, completing forty-six years of practice. He was fitly mourned by the entire village, and all business was suspended during the funeral ceremonies.

Dr. Charles A. Powers has resigned his position as Attending Surgeon to St. Luke's Hospital, and to the New York Cancer Hospital, and has removed to Denver, Col.

Medical Society of Virginia.—The Twenty-fifth Annual Session of this Society will be held in Richmond, Va., beginning October 23, 1894. An interesting programme is offered. The president of the society is Dr. William P. McGuire, of Winchester, and the secretary, Dr. Landon B. Edwards, of Richmond. The address to the public and profession will be delivered by Dr. R. S. Martin, of Stuart, Va.

Physicians on a Strike.—The daily papers state that the physicians of Mount Vernon, N. Y., are on a strike. They have announced that they will not examine lunatics, because the Board of Supervisors of Westchester has cut down the charge from $10 to $5 for each case. There are two insane prisoners in the Mount Vernon jail waiting the result of a doctor's verdict.

Chicago has 22 general and 16 special hospitals, with 3,409 beds.

The Chicage Health Board has adopted the New York plan of supplying culture-tubes and making microscopic examinations in cases of suspected diphtheria.

Women in Medicine.—Without egotism, we think that the women in medicine as a class are superior to men as a class; because it is the picked woman, the ambitious woman, whose desires are above the common level, who enters the profession. It takes grit and gumption to be a woman physician even to-day, for the woman in the profession must have a double motive for success: she must succeed for her own sake as well as for the reputation of capability all women desire. This may not seem fair, but it is nevertheless true. — *Woman's Medical Journal.*

Medical Journals in the United States.—There are two hundred and twenty-one medical journals published in the United States, but then there are one hundred thousand physicians.

Take a Vacation.—Dr. Alexander Stone says: "Doctor, whatever you do, do not forget to take your vacation. I can assure you that you will be able to do more work, better work, make more money, enjoy life fuller and live longer, if you work eleven months in the year, than you would if you labored for twelve." But perhaps some of the doctors' hearers feel as the tramp did when advised to take three regular meals a day.

A Medical Populist.—The *Medical Sentinel* says that the democrats and populists of North Dakota have nominated Dr. M. F. Merchant, of Ellendale, for State Commissioner of Labor. *The Sentinel* adds: "Of all the nominations made so far this fall in any of the States,

this is one of the most appropriate. What man of all men understands so well what 'labor' means?" Dr. Merchant is perhaps the first medical populist who has run for office.

Sugar as an Oxytocic.—A French obstetrician, Morso, asserts that sugar is an excellent and useful stimulator of uterine contractions during labor. He gives an ounce dissolved in eight ounces of water, and reports ten successful cases. Sugar is a direct stimulant to smoothe muscular fibres.

A New Method of Giving Thyroid Extract.—Dr. Edward Blake writes to the *Provincial Medical Journal* that in a case of myxœdema in which thyroid extract was not tolerated by the mouth, twice a day, after hot sponging and vigorous towelling, the body was well rubbed all over with the following mixture:

℞ Thyroidine..... 10 parts.
Ether..... 60 parts.
Lanoline .....480 parts.

A rise in the temperature of one degree followed the inunction, showing that the extract was really absorbed. This proceeding was well borne, and was followed by satisfactory results.

The Library of the French Academy of Medicine — Dr. Dureau, the librarian of the Academy of Medicine at Paris, gives some interesting details concerning his charge in a recent report. The library contains 147,405 volumes, including pamphlets, of which 8,164 were contributed during 1893. The greater part of these works was due to generous benefactors. Among other curiosities the library contains a collection of six thousand engravings and portraits of medical men, the greater number having been presented by a country doctor named Munaret, who for upward of forty years has been an ardent collector.

Further Reports Upon the Value of the Antitoxin Treatment of Diphtheria —M. Roux has communicated the following statistics with regard to the trial of the remedy at the Hôpital des Enfants Malades in Paris. Between February 1st and July 24th, 448 children were admitted into the diphtheria pavilion. Of this number 109 died; a mortality of 24.33 per cent. This was to be contrasted with the mortality in the four previous years, when 3,971 cases were admitted, and 51.71 per cent. died. The improvement in the death-rate attributable to the treatment was therefore 27.38 per cent. If compared with the mortality among the cases of diphtheria admitted during the same period into the Hôpital Trousseau the results appeared still more satisfactory. Of 500 children admitted into that hospital 316 died; a mortality of 63 20 per cent. A critical examination of the statistics for this year involved the drawing of a distinction between cases of true and false diphtheria. Of the 448 children admitted into the diphtheria pavilion, bacteriological examination showed that 128 were not infected with true diphtheria; further, 20 of the cases were already moribund when admitted. There remained, therefore, 300 cases which afforded a fair test of the efficacy of the treatment; they yielded 78 deaths, a mortality of twenty six per cent., which was to be contrasted with an earlier series of cases subject to the same eliminations but treated by other methods, which gave a mortality of fifty per cent. The rule had been to give an injection of the serum, which was obtained from the horse, immediately after the admission of the child. The injection was not repeated if bacteriological examination showed that the case was not one of true diphtheria. In none of these cases was the injection followed by any unfavorable symptoms; it was not painful, and if made with aseptic precautions was not followed by any local disturbance. In cases of true diphtheria a second injection was given twenty-four hours after the first, and as a rule this was sufficient. If the temperature remained elevated a third injection was given. As a rule a child received an amount of serum equivalent to one-thousandth of its weight, but in a few cases the quantity reached one-hundredth of the child's body weight. Under the antitoxin treatment complications were observed in only a few cases, but in some paralysis supervened. Occasionally during convalescence an urticarial eruption was observed, apparently due to the injections. The treatment appeared to diminish the liability to albuminuria. Dr. Aronson, of Berlin, states that he employs serum of the immunized horse, which is three times stronger than that of Professor Behring. In the five months ending with July he had treated with his serum 192 patients suffering from diphtheria, as ascertained by bacteriological examination. The mortality was fourteen per cent. In twenty-three cases the children were moribund when admitted; eliminating these there remained 169 cases with 19 deaths—a mortality of 11.2 per cent. This contrasted with a mortality in the same hospital varying in the three years before the adoption of the antitoxin treatment from 32.5 per cent. to 41.7 per cent. Eighty-two cases had been treated by the serum in other hospitals in Berlin, and the general mortality of the whole series of 274 cases was 15.3 per cent. He had also employed the antitoxin serum with the object of producing immunity in the children belonging to families in which one case of diphtheria had occurred. Among the 130 children thus inoculated 2 only contracted diphtheria, and that of a very mild type.

The Health of the Czar.—There seems to be no doubt that the Czar of Russia is seriously ill, though the reports as to the nature of his malady are very contradictory. He has been said to have diabetes, influenza, simple coryza, rheumatism, mental disease, Bright's disease, epilepsy, and apoplexy. It appears probable, however, that the trouble from which he is suffering is nephritis, following upon the attack of influenza and pneumonia with which he was visited last winter. Professor Leyden, of Berlin, was called to see the Czar in consultation with his regular physician, Dr. Zakharin, and has advised him to pass the coming autumn and winter in some mild climatic resort in southern Europe. He has gone temporarily to Livadia in Greece.

Medical Legislators in France.—The medical members of the French Parliament held a meeting on June 21st in the Palais Bourbon, and decided on forming an extra-parliamentary group which should occupy itself with the examination of the numerous questions concerning the medical profession, the organization of charitable institutions, and the public health. There are in the two Chambers no fewer than forty seats occupied by members of our profession; and there are also two medical men in the Cabinet, Drs. Lourties and Viger.

The Southern Surgical and Gynecological Association will hold its seventh annual session at Charleston, November 13th, 14th, and 15th. The meeting promises to be the most successful in the history of the organization. Papers will be presented by the leading surgeons and gynecologists of the South. The medical profession is cordially invited to attend. Dr. Cornelius Kollock, of Cheraw, S. C., is president, and Dr. W. E. B. Davis, of Birmingham, Ala., secretary.

A New Carriage for Medical Men.—Medical men, says *The Lancet*, will be interested in a new "interchangeable" or "convertible" carriage, which has recently been introduced. It has been shown at the Coaching Exhibition recently held at the Royal Aquarium. It is a radical change in the method of building convertible carriages. The inventor builds a foundation consisting of wheels, undercarriage, and driving seat, and upon this he places the movable bodies, forming an open or a close carriage of perfect shape in either case, and free from such defects as draught, rattle, and complication of parts. This carriage will enable its owner in crowded towns, where coach-house room is scarce and dear, to keep an open and a close vehicle—for there are practically two carriages in the space usually occupied by one. The change from brougham to victoria, or *vice versa*, is readily and easily made in the coach-house, and the carriage in either form cannot be distinguished from the ordinary private brougham or victoria.

Treatment of Diarrhœa, Whooping-cough, and Nocturnal Enuresis at the Evelina Hospital for Sick Children.—At this season of the year, writes the London correspondent of *The Therapeutic Gazette*, the most common ailment in the medical department is diarrhœa. Dr. Fenwick tells me that his experience leads him to rely chiefly upon antiseptics in such conditions. His favorite remedy is benzo-naphthol, which is given in grain doses thrice daily, even to very young children. It will be remembered that benzo-naphthol is a benzoate of β-naphthol, and that it is said to break up in the intestine into its constituents, both of which have an antiseptic action. Another remedy much used in this condition is carbolic acid, which is given in minim doses, either as a mixture or in the form of perle. Some of the physicians prefer creolin, giving it in drop doses on sugar, and in many cases this treatment is highly successful. Its nauseous odor and taste, however, prevent its finding favor with children. Lastly, creosote is used by some, but this is open to the same objections, and to a greater degree, as those already referred to in regard to creolin. Whooping-cough comes so often under treatment that it has been deemed desirable to devote a whole ward to the treatment of this affection. The most successful of all drugs at present in vogue is bromoform. It is given in doses of from 1 to 5 minims, either suspended in syrup or in a mixture, the taste being concealed by means of paregoric or some other flavoring ingredient. The drug does not appear to alter the duration of the affection, but is most useful in checking the paroxysms of cough and vomiting. I do not know whether it is a matter of common observation in other institutions, but I am given to understand that quite a large proportion of the serious cases of whooping-cough admitted at the Evelina develop miliary tuberculosis after admission. Another ailment frequently met with in all children's hospitals—nocturnal incontinence—is generally treated by the application of the faradic current, used as strong as the patient can bear it. One pole is applied to some neutral point, such as the nape of the neck, and the other is applied to the perineum, the latter electrode being more or less cone-shaped, and provided with a movable covering of either chamois leather or, better, of amadou. With this arrangement a fresh covering can be used for each patient. Improvement is generally very rapid, and the trouble often ceases after a few applications of the current. Should it relapse, a renewal of the treatment is attended with equal success. Treatment by such means is found to be far more successful than by any of the drugs, such as belladonna, which were formerly employed, but which, if used at all, are given solely as adjuncts to the electrical treatment.

Society Reports.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Seventh Annual Meeting, held in Toronto, Ontario, September 19, 20, and 21, 1894.

FIRST DAY, WEDNESDAY, SEPTEMBER 19TH.

THE Association met in the Council Chamber of the College of Physicians and Surgeons at 10.15 A.M., and was called to order by the Second Vice-President, DR. GEORGE F. HULBERT, of St. Louis, Mo.

An Address of Welcome on behalf of the local medical profession was delivered by Dr. James Thorburn, which was responded to by Dr. Hulbert.

The Incision in Abdominal Surgery—Methods and Results.—DR. J. HENRY CARSTENS, of Detroit, read a paper with this title, of which the following is a summary:

1. With a small, narrow-bladed, sharp knife, make a clean incision through the skin of the necessary length, and with another sweep or two cut through the linea alba, muscle, etc. Lift the peritoneum with your fingers, open it, and enlarge the incision. The use of the forceps to lift the tissues, or the grooved director is unnecessary.

2. In closing the abdominal incision use animal ligature, kangaroo tendon, and catgut. First carefully bring together the peritoneum in a running stitch, then the transversalis fascia, and the rectus if the incision is through this muscle. Then carefully bring together edge to edge the tendinous insertion of the oblique muscles. The fat and loose cellular tissue above can be brought together in one or two tiers, according to thickness. Bring the skin together carefully with Marcy's cobbler stitch, thus burying all your sutures.

3. Then seal with collodion, and if everything connected with the operation has been carefully aseptic, absolute primary union will take place, and the different layers of the abdominal wall will have been brought together as near as possible as they were in the first place, and no hernia will result.

4. In cases of extensive umbilical, ventral, or other hernias, it is best to bring the peritoneum together with an over-and-over stitch of kangaroo tendon or catgut; to make a flap splitting operation of the ring, which is brought together with silkworm gut or silver wire, which are buried, and then the fat and skin are united with the buried animal suture.

Plastic Surgery in Gynecology.—DR. JOSEPH PRICE, of Philadelphia, read a paper on this subject, in which he said that the practice of surgery in all its branches required a mechanical trend and an ability to devise means to accomplish a given end. In order to mend a perineum intelligently, the mechanism of labor must be understood

and the lines of fracture appreciated. In cases of serious pelvic invasion with accompanying lacerated cervix, it is often better, or imperative, first to do the pelvic operation, and to follow this at another time with the cervical repair. The author condemns the plan advised by some to perform internal and external operations at one sitting. Perineal tears always occur at certain parts of the perineal structure. These tears are either lateral, under the ramus of the pubes, or central, extending from the vagina toward the rectum. The tears toward the rectum tend to run around it rather than through it, owing to the differentiation of structure in these two tubes. The tears of the vagina are always from within outward, from above downward, and that therefore the external or skin operations for perineal lacerations are essentially unscientific procedures. All operations for the restoring of the integrity of these parts should be done in the lines of their destruction, and therefore from within outward and from above downward. When the skin of the perineum is involved, mending of this is merely a cosmetic procedure. The cosmetic element too often predominates in many of the so-called perineal devices. The silk-worm gut with shot is by far the most preferable material to be used for sutures. As little tissue as possible is to be included within the ligature, and strangulation is to be avoided.

The Care of Pregnant Women.—Dr. W. B. Dewees, of Salina, Kan., read a paper in which he held that the paramount duties of the obstetrician in the study and care of pregnant women may be classified as follows: 1. To discover if the patient be actually pregnant. 2. To determine positively if the impregnation be uterine or normal as contradistinguished from tubal, abdominal, or abnormal pregnancy. 3. To carefully note the pregnant woman's history, including her age, primiparity, or multiparity, environments, station in life, general condition of health, period of gestation, as well as her dress, food, drink, and habits of life. To make repeated examinations of the urine and ascertain the temperature from the time pregnancy is established to the termination of gestation. 4. To make a physical examination for the purpose of accurately determining the diameter of the pelvic straits; the symmetry and size of the bony outlet; the integrity, condition, and position of the vagina, uterus, and other intra-pelvic viscera, and adjacent structures; the state of the abdominal muscles; the presence or absence of hernia, varicose veins, tumors, etc., the shape, size, and condition of the breasts and nipples; the condition of the heart, lungs, mind, stomach, bowels, etc. 5. To observe the state of the fœtus, its strength and viability, as well as the implantation of the placenta. The thoughtful obstetrician will advise his patient as to the requisite régime. The consciousness of his full duty will impulse him to insist upon: 1. Absolute regular hours and wholesome environments. 2. Plain but nutritious and wholesome food and drink, being principally composed of fresh lean meats, fresh fruits, pure milk, and distilled water. 3. A proper amount of exercise, by walking or light labor on foot, and maintaining the correct erect posture. 4. An open condition of the bowels and skin, which is to be chiefly maintained by proper diet, exercise, and bathing, the wearing of flannels, warm low-heeled shoes, and loose garments, and in rare cases the proper use of laxatives and hot-water enemas.

Appendicitis, With Report of Cases.—Dr. George S. Peck, of Youngstown, O., read this paper.

Case I.—Operation during interval of attacks; obstruction; July 6th did second operation; recovery. Operation July 27, 1894. Appendix buried in mass of strong adhesions between ileum and cæcum containing large fecal concretion. Appendix removed in segments. Ileum returned to abdominal cavity. During first six days highest temperature 100° F.; pulse, 100. On the fifth day four attacks of vomiting, fourth containing fecal matter. August 4th reopened incision; found about three feet from ileo-cæcal valve complete obstruction by band of dense adhesions. Obstruction liberated, ileum brought out in the incision, and abdominal cavity packed with gauze. During entire day of August 1st pulse ranged from 140 to 160; vomiting fecal matter continued at frequent intervals; tympanites increasing. Seven o'clock symptoms of obstruction continued, becoming worse every hour. As a temporary expedient a small opening was made in ileum, fetal matter and flatus came away in large amount; vomiting ceased and tympanites disappeared. From the thirteenth day to the present time patient has had from one to three daily passages per rectum; sat up for the first time the thirty-third day. Discharged from hospital on the fifty-fifth day after first operation.

Case II.—Operation during the fourth day, first attack. Large appendix removed, containing two drachms of pus and fecal concretion. Adhesions broken up, incision packed with iodoform gauze. Uninterrupted recovery. Discharged from hospital twenty-eighth day after operation.

Case III.—Operation third day of third attack. Peritoneal cavity opened, adhesions broken up; large appendix removed; uninterrupted recovery.

Case IV.—Operation during tenth day. Death from septic peritonitis in sixty-five hours. Large abscess cavity evacuated; appendix gangrenous and detached; washed out by irrigation. Autopsy revealed general septic peritonitis.

Case V.—Perforating appendicitis. Operation during third day of attack. Death from septic petitonitis twenty-seven hours or more after operation.

Case VI.—Similar to previous one, died from general septic peritonitis.

Appendicitis; Observations Based on a Clinical Study of Eighty-four Cases.—Dr. W. G. McDonald, of Albany, presented a communication with this title. Out of the great amount of literature, controversial and otherwise, three important landmarks are established: 1. That for all practical purposes all inflammatory processes in the right iliac fossa arise from the appendix. 2. That practically the appendix is always intra-peritoneal, and that any operation undertaken for appendicitis that does not involve the entering of the peritoneum is false in its surgical conception. 3. That idiopathic peritonitis does not occur. That many cases diagnosticated as such, are really cases of perforating appendicitis. The author classified the varieties as 1, acute perforating, fulminating appendicitis with general peritonitis; 2, acute suppurating appendicitis with local plastic peritonitis and abscess; 3, subacute appendicitis, variously termed catarrhal, chronic, relapsing, or obliterating appendicitis, or appendicular colic. The perforation occurs very much earlier than is commonly believed. That acute suppurative appendicitis with local peritonitis presents the most favorable field for operation during the attack. The removal of the appendix is to be undertaken with great circumspection when it lies in the wall of an abscess cavity. The third group of cases do not require operations during the first attack, but if repeated attacks occur, operation during quiescence is demanded. Operative results in these cases are most favorable.

Second Day, Thursday, September 20th.

Ligation of the Uterine Arteries for the Cure of Fibroid Tumors and Checking Hemorrhage.—Dr. W. B. Dorsett, of St. Louis, read a paper with this title. The object of which, he said, was to establish his priority in resorting to ligation of the uterine arteries for the cure of fibroids. He made observations during December, 1889, and January and February, 1890, and reported a case of atrophy of the genitalia and described the technique of the operation of ligation of the uterine arteries for the cure of fibromatous growths in a paper read before the St. Louis Medical Society, May 17, 1890, and which was published in the *St. Louis Courier of Medicine*.

Remarks on the Surgical Treatment of Intussusception in the Infant Based on Two Successful Cases.—Dr. Henry Howitt, of Guelph, Ont., read the paper. In it he recommends early abdominal section as being the best method of treatment to reduce the high mortality rate of intussusception in early infancy. Of the two cates cited, one child was at the time of operation under three, and the other under six months of age. In regard to the steps of the operation, among other things he advises a small median incision; evisceration; reduction by pressure on apex of intussusceptum, while the intussusception is drawn in the opposite direction; and forcing the contents of ileum into colon before returning the intestines to abdomen.

Dr. Robert T. Morris, of New York, demonstrated a method of intussusception in rabbits.

Treatment of Distention of the Fallopian Tubes Without Laparotomy and Removal.—Dr. Frank A. Glasgow, of St. Louis, read a paper which was intended to bring before the profession a method of curing tubal distention by means of intra-uterine treatment, in contradistinction to laparotomy and removal. By this means the uterine ends of the tubes are made more patulous and a discharge takes place from the tube through the uterus. He called attention to the fact that the tubes, as far as his observation goes, are always pervious at the outer extremity of the cornu, hence when removing them we must always clamp them before cutting. The obstruction must be within the uterine wall, probably in the endometrium, and also to the fact that gonorrhœal inflammation is not an adhesive inflammation, and hence it does not follow that the tubes have a true atresia following this inflammation. His opinion is that the closure is due to a swelling of the endometrium, and hence a closure at the uterine end takes place. When this inflammation and swelling are overcome by pressure and antisepsis, the tubes become patulous again. The intra-abdominal pressure will cause fluid in any pendant portion of the tube to ascend into the uterus. The above procedure can be carried out in three different ways: 1, By gradually packing with gauze without anæsthesia; 2, by rapid dilatation of the cervix and packing with gauze after curetting—this is done under anæsthesia—3, his own method of dilating by means of antiseptic or sterilized elm-bark tents. These tents are small strips of elm bark made just long enough to enter the cervix completely and not press on the fundus. They should be kept in an alcoholic solution or bichloride of mercury, 1 to 4,000, and have a short string attached, by means of which they may be withdrawn. They are partially broken in a number of places for the purpose of making them more pliable. They may be dipped into glycerine or water just before introduction. These tents may be used when it would be impossible to pack with gauze. He had treated twenty or more cases during the past year, and does not recall one in which he did not get some discharge from the tent. All of the cases were either cured or very much benefited.

Inflammatory Disease of the Uterus and Appendages and of the Pelvic Peritoneum.—Dr. William W. Potter, of Buffalo, presented a communication with this title. He began by recalling the well-known fact that the pathology of pelvic disease has been entirely reconstructed since 1860, and that now we had come to regard inflammation of the pelvic peritoneum as generally symptomatic of disease of the ovaries or Fallopian tubes, or both. Mr. Tait, within the last ten or twelve years, together with men who have worked abreast of him—some of whom are members of this Association—have driven out the theory of pelvic cellulitis that for so long held sway, and now peri- and parametritis have been dropped from the gynecological vocabulary. The struggle has been a long one, but abdominal surgeons have demonstrated the truth of this proposition, viz., that pus originating outside of the tubes or ovaries in the non-puerperal state is a very rare condition, and that speaking generally pelvic are pus tubes. The largest number of women in the consulting rooms of gynecologists are those suffering from pelvic inflammation or its residues, hence the importance of the subject under discussion cannot be overestimated. But, he asserted, it is only within the past seven or eight years that anything like uniformity of opinion as to the causes and proper treatment of pelvic inflammation have been adopted. Now, just as we are beginning to agree as to the essentials governing these cases, we are told by a number of agreeable gentlemen who call themselves conservatives that these diseases do not demand operation, but that they can be cured in most instances by tentative measures, such as diet, rest, electricity, and the like. By denouncing the work of abdominal surgeons as unnecessary mutilation, and stigmatizing it as castration or unsexing women, they have created a panic among the medical journals that is reaching far into the ranks of the profession. The effect of this is to turn back the wheels of time and stay the advance of progress, with harmful results to suffering women. It must be admitted that these so-called conservative men are clever, which makes their subtle and dangerous doctrine all the more damaging in its results.

Dr. C. A. L. Reed, of Cincinnati, discussed the clinical history of inflammatory disease of the uterus and appendages and of the pelvic peritoneum; Dr. L. S. McMurtry, of Louisville, the causation and pathology; Dr. James F. W. Ross, of Toronto, diagnosis and prognosis; Dr. M. Rosenwasser, of Cleveland, the treatment, along with Drs. A. Vander Veer, J. Henry Carstens, and Dr. Joseph Price.

Pus in the Pelvis and Abdomen—its Diagnosis and Treatment.—Dr. Joseph Hoffman, of Philadelphia, said that pus in the abdominal and pelvic cavities had been treated and considered with far more leniency than pus anywhere else in the human economy. It was the tramp manifestation of all disease. He considered briefly the various organs in which pus makes its appearance, and in the order of frequency he mentioned the kidneys, appendix vermiformis, tubes and ovaries, liver, pancreas, and spleen. Each case should be treated according to the demands it makes and according to its complications. There was no use in doing an ideal operation and have the patient die when it is over. Ideal work was that which gives the best result in the line for which it was done. Surgery of the abdomen was a work of self-denial, of trial, of unexpected complication, and lurking disaster. He best can rise to it who has for his motto, "My Patient. Nothing but for the good of her who trusts me." Self-seeking carelessness of lives has its place in the carnage of internecine strife, not in the shadowy sorrows of suffering humanity, of dying women.

A New Operation for the Radical Cure of Inguinal and Femoral Hernia.—Dr. C. A. L. Reed, of Cincinnati, described the operation as follows: The incision in inguinal hernia is made from a point two inches above Poupart's ligament, midway between the anterior superior spinous process of the ilium and the spine of the pubis, obliquely downward and inward as nearly as possible consistent with the access of the inguinal canal to a point at the base of the scrotum. The dissection is then carried into both scrotal and pelvic cavities. The protruding viscera is then reduced and carefully inspected after being brought out above. The sac is then carefully dissected from its scrotal connections and reversed by invagination. It is then opened by two incisions, one toward the pubes, the other toward the ilium, being thus converted into an anterior and a posterior flap. The cord is now dissected loose and placed in the canal, now denuded of its peritoneum at its outer angle. The internal ring is closed by several interrupted sutures, animal or buried silk, these sutures being applied beneath the peritoneal flaps formed by splitting the sac, care being taken that in the closure of the ring undue pressure shall not be brought to bear upon the cord. The posterior peritoneal flap is now excised, the stump

being ligated should there be any necessity for doing so. The anterior flap is carried across the now obliterated internal ring, and stitched by interrupted sutures to the posterior parietal peritoneum. The external ring is now closed by passing a number of sutures through its pillars externally to the cord, which is now fixed in the internal (pubic) angle of the outlet of the canal. The incision into the abdomen is closed by interrupted figure of eight sutures, the internal loop embracing the peritoneum, the aponeurosis of the transversalis and of both oblique muscles, and the external loop embracing the superficial fasciæ, fat, and skin. These sutures should not be more than three-fourths of an inch apart. The incision into the scrotum may be closed in the ordinary way. Drainage should not be employed except in the presence of marked oozing or obvious infection.

Ovariotomy.—Dr. A. Vander Veer, of Albany, presented a report of one hundred and forty five operations done for removal of ovarian tumors and pathological conditions associated with the ovaries and uterine appendages only. He gave a careful review of the subject of the preparation of patient, embodying all the strong points pertaining to the technique of such work, placing great stress upon the importance of the room in which the operation was to be done being put in a thoroughly aseptic condition, and thorough cleanliness of the patient herself. The operations comprise all the varieties of pathological conditions met with in connection with the ovaries and tubes. The histories of the cases were somewhat interesting. Thirty-nine gave a history of phthisis, fifteen of cancer, fifty-seven of irregularity of menstruation. The mortality amounts to eleven per cent. While not criticising adversely the methods of other operators in closing the wound by means of different rows of sutures, kangaroo tendon, and other forms, yet he has no reason to give up his usual method of closing the wound by deep sutures of silk worm-gut, placing them three or four to the inch, taking in carefully only a margin of the skin, a portion of the fascia and muscles, and not to exceed one-quarter of an inch in width of the peritoneum itself, placing much stress upon the importance of careful, thorough, complete apposition. The causes of death in the seventeen cases were as follows: Obstruction of the bowels due to a coil of small intestines becoming attached to the stump of the pedicle, causing death on the fourth and fifth day, two cases. Septic peritonitis, two cases. Immediate hemorrhage from the pedicle, slipping of the knot, within six hours after the operation, though the wound was reopened, the vessels secured, abdomen flushed, and hemorrhage controlled, one case. Undoubted hemorrhage from the pedicle, causing general peritonitis, although no distention of the bowels was present, death on fourteenth day, one case. Shock within twelve hours after operation, one case. Shock within twenty-four hours after operation, one case. Autopsy in both cases revealed everything in good condition. Pulmonary infarction on sixth day, one case. Aggravated diabetes, one case. Exhaustion on the sixth day, no other apparent cause found, one case. Another case of exhaustion on the third day, symptoms in the last two cases, including an autopsy not revealing any other cause. Multilocular ovarian cyst, tapped twice, operation complicated with four months' pregnancy, one case. Puerperal septicæmia, one case. Intestinal obstruction on twenty-first day, one case. Advanced age complicated with the recent effect of an attack of la grippe, one case. Delayed operation in a case of extra-uterine pregnancy possibly four months, one case.

Hydrosalpinx.—Dr. A. H. Cordier, of Kansas City, read a paper with this title. He said articles had appeared in medical journals by the so-called conservative writers in the last few months, in which aspiration or catheterization of the Fallopian tubes filled with liquid of any character had been advocated as a procedure of relief and cure. Such articles had engendered a retrograde tendency on the part of many, and it is sure to be at the expense of an increased mortality from subsequent operative procedures to cure these cases after abandoning the unsurgical and uncertain tinkering. Hydrosalpinx had been looked upon as the least hazardous of all inflammatory results to the Fallopian tubes. The writer claimed that hydrosalpinx was a sequel of some old inflammatory diseases of the tubes, an offspring of a virulent process that had wrought permanent and irreparable injury to the delicate structures of the tubes. The writer did not consider hydrosalpinx as a retention cyst. Cases were rarely diagnosed prior to operation. A digital examination of one of these cases causes less pain than is produced in examining a pyosalpinx. In one case, occurring in the essayist's practice, the uterine extremity of the tube was largely dilated and filled with a clear fluid, while in the ampulla there existed a collection of pus, separated from the clear fluid by a closed stricture.

Inflammatory Disease of the Uterus and Appendages under Various Modes of Treatment. — Dr. Joseph Price, of Philadelphia, said that the methods of treatment of pelvic disease may be broadly classed as those that are proved, and those that are experimental. Many of the operations now successful were formerly failures because of the insufficient knowledge of how to deal with a wounded gut, how to make an anastomosis, or to do a bowel resection. Hence it is to be put down as a postulate in pelvic surgery that no man has a right to attempt it who does not know how to deal with all the complexities of intestinal surgery. To know when to stitch and when not to stitch the intestine is as necessary as to know when and when not to operate. The leaving of pus-tubes to recover of themselves is just one step removed from stuffing them with gauze and trusting to Providence. To puncture and evacuate and stitch a suppurating cyst—say a real ovarian cyst—would be derided out of sight, and yet, said the essayist, we have operators who do not hesitate to do this with the smaller pus-tube.

Dr. George H. Rohe, of Catonsville, Md., said that conservative surgeons were very much shocked at first by the proposition to remove the uterus together with the adnexa in cases of inflammatory disease in the pelvis. However, the operation has won its way against opposition, and must now be considered as an elective procedure in cases of extensive suppuration with adhesion, and especially in those cases, so numerous, in which the endometrium is likewise the seat of purulent inflammation. Gonorrhœal, puerperal, or tubercular inflammations and dense adhesions, with displacement of the uterus, demand removal of this organ as well as of the appendages if permanent good results are expected. Total extirpation of the uterus and appendages by the vaginal method for pelvic suppuration was first done by Pean in 1886. Pean, Segond, Doyen, Jacobs, and Landau have performed the operation upward of five hundred times with an average mortality of less than five per cent. The operation by the vagina is easier than abdominal extirpation, and in the hands of most surgeons who have performed it, is attended by less shock. It leaves the parts in condition for perfect drainage. The after-treatment is simple. Patients may sit up in a week or ten days. Forceps are preferred to the ligature for hemostasis.

How Shall we Deal with Pelvic Inflammatory Troubles?—Dr. W. B. Dorsett, of St. Louis, Mo., presented a paper with the following conclusions: 1. Pus in quantities is hard to deal with down in the pelvis in laparotomy cases, and, if possible, should be evacuated prior to taking out the tubes and ovaries, either through the cul de-sac of Douglas, or if between the layers of the broad ligament, at the side of the uterus, laparotomy should be done at some future time. 2. Pus sacs in the tube near the uterine end of the tube can be evacuated through the uterus by packing the horn. 3. Parametritis or cellulitis of the ancients is, except under rare instances, a secondary trouble due to a foul uterine cavity. Clean

out the cavity and stop the source of poison, and you do the best thing possible to be done.

The Relations of Renal Insufficiency to Surgical Operations.—Dr. C. C. Frederick, of Buffalo, reported observations based on nearly three hundred operations at the Buffalo Woman's Hospital, supplemented by the experience of several prominent operators. By renal insufficiency is meant any condition of the urine which shows deficient elimination of waste products, whether from functional inactivity or from disease of the kidneys. Whether renal insufficiency is a contra-indication to operation depends on the consideration of three factors: 1. The amount and nature of the insufficiency. 2. The character of the lesions for which operation is proposed. 3. The causal relation which the patient's disease holds to the renal insufficiency. Every patient's urine before operation should be collected for twenty-four hours, except when operation is urgent, as in ruptured ectopic pregnancy, for example. In examination of urine the important fact to ascertain is, whether the kidneys are crippled, or in full or nearly normal functional activity. Women with chronic endometritis are especially liable to functional insufficiency. Most gynecological patients who are run down physically present the same condition. A knowledge of the state of the patient's kidneys is of value to the operator and anæsthetizer. Renal insufficiency renders the patient more liable to shock from operation, and a slower convalescence.

The Cause of Thirst following Abdominal Section.—Dr. Eugene Boise, of Grand Rapids, Mich., after stating the generally accepted proposition that thirst is a sensation indicating that the tissues of the body are in want of more water, argues that the sensation as felt in the mouth and throat is reflex, and that the real point from which the sensation arises is in the abdominal viscera; that from these the sensation is conveyed to the consciousness by fibres of the sympathetic system of nerves; that while ordinary thirst is caused by the withdrawal of water from the tissues to refill the veins depleted by excessive perspiration or otherwise, the thirst following abdominal section is caused by the withdrawal of water from the abdominal viscera to fill veins partially collapsed by reason of diminished blood-supply because of contraction of the arteries of the viscera. He briefly stated those physiological facts which are universally accepted or have been experimentally proven on which the theory is based: 1. Thirst is a sensation indicating that the tissues need more water. 2. The sensation felt in the throat is reflex. 3. The origin of the sensation is believed by leading physiologists to lie in the sympathetic system of nerves, because (*a*) no cerebro-spinal nerves can be found which convey the sensation to the consciousness, and (*b*) nutrition is presided over by the sympathetic system, and thirst is a disturbance of nutrition. 4. The origin of the sensation is probably from the abdominal organs, because (*a*) these are so rich in sympathetic fibres, and (*b*) introduction of water into the stomach so instantaneously allays thirst. 5. The sensation invariably follows the withdrawal of any considerable amount of fluid from the body; the withdrawal of such fluid causes proportionate collapse of veins and capillaries. 6. Capillaries tend to remain at normal tension, and when suddenly collapsed in any degree attempt to regain that tension by taking water from the surrounding tissues. 7. Irritation of sympathetic nerves causes contraction of the arterioles supplied by such nerves. 8. Sudden contraction of the arterioles supplying any organ is followed by lessened tension in the capillaries and small veins of that organ. 9. Abdominal section invariably causes direct and reflex irritation of the abdominal sympathetic nerves. 10. Such irritation causes contraction in some degree of the arterioles of the abdominal viscera, with subsequent lessened tension in their capillaries, and compensatory withdrawal of water from their tissues. And is it not probable that such circulatory disturbances give rise to the sensation of thirst?

President's Address.—Dr. Rohe then delivered his address. He selected for his subject "Intestinal Obstruction following Operations in which the Peritoneal Cavity is Opened." He said obstruction of the bowels causes between one and two per cent. of the deaths following ovariotomy and other operations involving opening of the peritoneal cavity. Sir Spencer Wells lost 11 out of his first series of 1,000 cases of ovariotomy from this cause. Fritsch places his mortality from ileus post laparatomian at 1.6 per cent. Klotz has reported 31 cases of intestinal obstruction, with five deaths due to this complication, in a series of 421 abdominal sections, and 148 vaginal extirpations of the uterus. The speaker had seen a case where the small intestine was doubled upon itself, and so firmly adherent that the gut was entirely impervious. Similar cases have been reported by Skutsch and Tuttle. Joseph Price quotes an interesting case from Louis, where an adherent ovarian cyst, emptied by the trocar, so dragged upon the bowel as to cause obstruction. Volvulus sometimes occurs after abdominal section, but probably only after some previous adhesion or constriction of the bowel. Two cases reported by Nieberding illustrate this. The symptoms of intestinal obstruction post laparatomian are essentially the same as those of primary obstruction. Klotz has had much success in treating acute obstruction following abdominal section by the following method: As soon as symptoms indicating obstruction appear, he washes out the stomach with from four to six quarts of warm salt solution. Should this fail to relieve the symptoms he repeats it, and then passes into the stomach through a tube a large dose (one and a half to two ounces) of castor-oil. In all cases so treated the active peristaltic movements set up caused passage of flatus and fæces within ten hours. Evidently it is only in cases of fresh and friable adhesions that this method can be successful. Rectal injections of water or air may at times be curative when the obstruction is due to intussusception, volvulus, or soft adhesions of the lower portion of the intestine, but where the obstruction is due to cords or bands they can manifestly be of no avail.

Third Day, September 21st.

Nephrectomy.—Dr. L. H. Dunning, of Indianapolis, Ind., reported four cases of this operation, of which the following is a synopsis:

Case I.—Nephrectomy for painful movable kidney. An unsuccessful nephrorrhaphy had been done two and a half years previously. The patient had been bedridden four years. A lumbar nephrectomy was done, the patient recovering and obtaining entire relief from pain. The author deplores the necessity of removing a healthy kidney only because movable and painful. He thinks that the success of recent methods for anchoring the kidney will obviate the necessity of such a procedure.

Case II.—Nephrectomy for persistent hydronephrosis due to stricture of the ureter at its pelvic extremity. The tumor was mistaken for an ovarian one. It was removed by a median abdominal incision.

Case III.—Sarcoma of the kidney in a child two years old. Nephrectomy and recovery. The tumor had been discovered only four weeks previously. A median incision (abdominal) was employed.

The writer has collected the histories of twenty cases of sarcoma of the kidney operated upon since 1885 in children under five and a half years of age. Of these five perished, and fifteen survived the operation, thus showing a mortality of twenty-five per cent. This is a surprising decrease in mortality, and is probably due to improved details in technique rather than to radical changes in the method of operation.

Case IV.—Nephrectomy for uretero-vaginal fistula following vaginal extirpation of a cancerous uterus. The operation was done four weeks after the hysterectomy. The ureter was torn across in enucleating a nodule of cancerous tissue from the folds of the broad ligament on removal of the uterus. Nephrectomy was done four weeks

subsequently because of intermittent closure of the fistula and the morbid mental condition of the patient. The cancer had recurred in seven weeks, and patient died three months later of exhaustion and septicæmia.

Progressive Cutaneous Atrophy of the Vulva (Kraurosis Vulvæ).—Dr. C. A. L. Reed, of Cincinnati, read a paper with this caption. He reported six cases in which the pathological and clinical features were characteristic. The first changes obvious to the naked eye consist of small vascular areas around the introitus vaginæ. These areas are not elevated, as if seats of merely inflammatory engorgement, but are slightly depressed relatively to the adjacent epithelial surfaces. They are exquisitely painful to the touch, and efforts at sexual intercourse are generally agonizing and futile. About this same time inspection will reveal a narrowing of the vaginal orifice associated with diminished elasticity of the structures. The cutaneous or muco-cutaneous surfaces will now be observed to have lost a certain proportion of their pigment, giving them a more or less translucent appearance, which increases until it becomes so transparent that the larger capillaries and minute ecchymoses may be readily discerned beneath it. The skin thus affected becomes tense, effacing in a more or less degree all of the normal folds of the vulva and narrowing the vaginal orifice until, in the case of a multipara, "incredulity may be excused when the patient states that she has borne children."

Knowledge relative to progressive cutaneous atrophy of the vulva is too nebulous to justify final conclusions. That which seems to be conclusively demonstrated may be summarized as follows: 1. Progressive cutaneous atrophy of the vulva is a distinct disease. 2. It is of very rare occurrence. 3. It is essentially inflammatory in character, differing from other inflammations of the skin in the marked progressive atrophy which succeeds the stage of hyperæmia and infiltration. 4. It is limited in its manifestations to the vulva. 5. It is manifestly not of syphilitic origin. 6. Its etiology is so obscure as to suggest a primary causal lesion in the trophic nerve-supply of the vulva. 7. The affected areas may be successfully excised.

Dr. George F. Hulbert, of St. Louis, read an interesting paper on "The Element of Habit in Gynecic Disease," an abstract of which would not do justice to its author.

One of the interesting features of the meeting were remarks on intestinal anastomosis and a beautiful demonstration of the uses of the Murphy button by Dr. J. B. Murphy, of Chicago.

Restoration of Intestinal Continuity Without Mechanical Devices.—Dr. W. E. B. Davis, of Birmingham, Ala., said that the purpose of this paper was not to claim originality for any special technique, but rather to consider the various operations and to show that mechanical devices can in a great proportion of cases be better dispensed with by the surgeon who has had much experience in intestinal work, either on the lower animals or on the human intestine. Still there is a place in anastomotic work for bone plates, catgut plates, and other devices of this sort, and the Murphy button, but the experienced surgeon will find the field of their application very limited. These devices are of great assistance to the surgeon of limited experience in this class of work, and should be recommended in the event of an operation having to be done by one who has not had the opportunity of becoming familiar and skilled in suturing of the intestines. The Murphy button is a valuable device for cholecystenterostomy, and is superior to anything yet suggested for that purpose. The button is so small that it can pass through the intestine without causing any trouble, and it can be depended upon with almost absolute certainty to produce satisfactory adhesion and a competent opening between the gall-bladder and intestine. The end-to-end operation or circular enterorrhaphy is a dangerous procedure, from the fact that injury to the mesenteric border is liable to produce sloughing, and it is never possible to say that a surgeon will not have this complication follow the operation. Besides any stitch method in the end to end operation requires so much time that it should be objected to usually on that account. The Murphy button can be used very satisfactorily for this purpose, and where end-to-end operation is to be resorted to, Dr. Davis is of the opinion that this device could be used unless the surgeon is an expert in intestinal suturing. The operation of Abbe is a plausible one, but it is not so reliable as the one which has proven satisfactory in the experimental work of the author. The incision is not made so long as in the case of Abbe, and is about three inches in length. In the case of gastro enterostomy the intestine and stomach are both brought into the wound, and the incision three inches in length made in both. Interrupted sutures are taken through coats of the bowel and stomach around the entire length of the incisions and are tied on the inside, the last stitch being tied on the outside and turned in. A continuous outside safety stitch is then taken through the peritoneal and muscular walls. In bringing the small intestine together the same procedure is followed, the interrupted through-and-through stitch of large silk being taken instead of an over-hand stitch, as recommended by Abbe, and only one row of outside sutures, which may be interrupted or continuous, preferably the latter. This operation can be done very quickly, and is more reliable than the various ones with mechanical aids to anastomosis. Particularly is this method of operating valuable in cases of simple stricture of the bowel, and there will be a great many of these cases now inasmuch as there are more operations done on the intestines.

Dr. F. Blume, of Allegheny, Pa., reported a very interesting case of cholelithiasis in a woman, thirty-seven years of age, in which the number of calculi removed, besides minute concretions, was one hundred and twenty-three, weighing fourteen drachms. The stone removed from the gall-bladder weighed four and three-quarter drachms.

The Reason why Patients Recover from Tuberculosis of the Peritoneum after Operation.—Dr. Robert T. Morris, of New York, stated that he had been experimenting with a view to determining the reason for the cure of tuberculosis of the peritoneum after operation, it being a well-known fact that more than eighty per cent. of these cases recover as a result of simply exposing the peritoneal cavity to the air. Dr. Morris collected fluid from the abdominal cavity of patients with tuberculosis of the peritoneum, placed it in an incubator for forty-eight hours, and developed the bacteria of putrefaction which would ordinarily enter in such fluid exposed to the air. From this fluid Dr. Eiloart then isolated a toxalbumin, the product of the growth of putrefactive bacteria in this peritoneal fluid. The toxalbumin employed to destroy tubercle bacilli in culture-tubes destroyed them very promptly. A control experiment, which was not yet completed, was in progress for determining if these bacteria were absolutely dead. However, enough had been proven to show that tuberculosis of the peritoneum recovers after operation because putrefactive bacteria produce a toxalbumin in the fluid which is fatal to tubercle bacilli in the peritoneum. The reason why it is more effective in curing cases of tuberculosis of the peritoneum than tuberculosis of the knee-joint is because the lymphatic anatomy of the peritoneum is such that any toxic agent absorbed by the lymphatics of the peritoneum is brought into close contact with the entire structure; whereas in the knee-joint the lymphatics are fewer and with more definite channels.

Election of Officers.—*President*, Dr. J. Henry Carstens, of Detroit, Mich.; *First Vice-President*, Dr. W. E. B. Davis, of Birmingham, Ala.; *Second Vice-President*, Dr. Henry Howitt, of Guelph, Ont.; *Secretary*, Dr. William Warren Potter, of Buffalo, N. Y.; *Treasurer*, Dr. X. O. Werder, of Pittsburgh, Pa.

The place of meeting for 1895 was referred to the Executive Council for decision.

Correspondence.

OUR VIENNA LETTER.

(From our Special Correspondent.)

THE EIGHTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY AT BUDAPEST—FOREIGN DELEGATES PRESENT—OPENING OF THE INTERNATIONAL HYGIENE EXHIBITION—RECEPTION OF THE DELEGATES BY THE ARCHDUKE CHARLES LEWIS—THE SEMMELWEISS MEMORIAL—WORK OF THE SECTIONS—THE CAUSE OF CHOLERA—CREMATION—IMMUNITY, NATURAL AND ACQUIRED—TYPHOID FEVER AND THE WATER SUPPLY.

VIENNA, September 13, 1894.

THE Eighth International Congress of Hygiene and Demography, which has just been closed, was brilliantly successful. About three thousand members, among whom representatives from various countries of the world participated in it. The number of ladies present was about three hundred. The Congress was opened on Sunday, September 2d, at eleven o'clock, by the Archduke Charles Lewis of Austria, in the place of the Emperor, who is the protector of the Congress, but who was prevented from being present at the opening ceremonies. The Archduke emphasized the great importance of the Congress, which served the purposes of humanity and civilization. The endeavors of the members of former international hygienic congresses to practically realize the resolutions of the Congress were partly crowned with success, and on this occasion the Archduke alluded to the fact that in various states new, regular, and obligatory courses on the principles of hygiene had been introduced into the public school instruction.

The Archduke, who hitherto had spoken in French, then began to speak in Hungarian, and saluted the beautiful capital of Hungary, congratulating her on the distinction which the Congress had bestowed on her by chosing their city as the place of present meeting. He did not doubt that the Hungarians would sustain on this occasion their world-wide reputation for hospitality.

The Archduke Charles Lewis then declared, in the name of the King-Emperor, the Congress opened. Among the foreign representatives who afterward addressed the Congress I will only mention Professor Leyden, of Berlin, who spoke in German; Professor v. Inama-Sternegg, of Poland (German); Dr. Bergerau, of France (French); Dr. Billings, of the United States (French); Dr. Crocq, of Belgium (French); Dr. Corfield, of England (English); Professor Don Amalis Girneno, of Spain (French); Professor Bambos, of Greece (French); Dr. Luigi Bodis, of Italy, (Italian); Professor Erismann, of Russia (Russian and French); Dr. Joao Lopez de Silva Martins, of Portugal (French); Dr. Hansen, of Norway (French), and others.

At 1 P.M. the International Hygienic and Demographic Exhibition was opened in the "Polytechnicum." This was divided into six sections, namely, sewage of towns, general exhibition of Germany, Austria-Hungary, and various other countries, cremation, and balneology.

On Sunday evening the Congress was received at court by his Imperial and Royal Highness the Archduke Charles Lewis, where a splendid banquet had been prepared for the guests. This meeting presented a particularly picturesque appearance owing to the different dresses of the representatives of the various states. The President of the Congress, State Minister of the Interior Hieronymi, presented the delegates of the foreign states and the other prominent members of the Congress to the Archduke, who addressed them in French and German, directing to them questions referring to their specialties and their countries. I wish to mention on this occasion as an interesting incident of the Congress the so-called "Semmelweiss-Sitzung," held on Sunday afternoon in the buildings of the Academy of Medicine. Semmelweiss was the first to introduce antisepsis into obstetrical practice, but during his life his doctrines attracted little favorable notice, and he was even persecuted by his colleagues. Medical science had long ago acknowledged the immortal services which Semmelweiss had rendered to the science of obstetrics and to humanity, and Hungary, which is always ready to reward the merits of her great men, decided on doing the last, and pay due homage to her great citizen, who was born at Budapest. A committee had been established for the erection of a monument in honor of Semmelweiss, and in the meeting now referred to, Professor Kézmarszky, of Budapest, president of the committee, made a report. A sum of 12,586 florins had thus far been collected; but subscriptions toward the erection of the monument were still being taken. Professor Ferdinand Hueppe, of Prague, delivered an address on Semmelweiss, which was received with great enthusiasm by all present. The members then betook themselves to the cemetery in which Semmelweiss is buried, to assist at the ceremony of the unveiling of his monument. On this occasion Professor Hueppe spoke again, and Professor Chautemesse, of Paris, delegate from France, answered in feeling words, saying, among other things, that if all the children whose lives Semmelweiss had saved were still living, the city of Budapest would be unable to hold them all.

On Monday the sections of the Congress proceeded to their work. There were nineteen sections, and the number of the papers announced amounted to nearly eight hundred, all of which, of course, could not be read. The sections on hygiene were most frequented, and among these, particularly the first, second, and third sections, in which questions of bacteriology and blood serum therapy were most eagerly discussed. Among the lectures which were delivered on the first day, that of Princess Christian of Schlesweig-Holstein, on the advances in nursing science, as well as on the spread of sanitary and hygienic knowledge in England during the past few years, attracted great attention.

In the other sections the discussions on diphtheria and cholera were among the most interesting. The discussions upon cholera were opened by Dr. Baker, of Paris, and Professor Gruber, of Vienna. The latter pointed out that besides the bacillus of Koch, there must still be some others. The famous Paris scientist, Professor Elie Metschnikoff, spoke to the same effect, and said that the vibrio of cholera could not be the sole cause of cholera. There were people who had ingested pure cultures of cholera bacilli without becoming infected with the disease. He had found in the stomach and the intestines other bacteria, which either favored or checked the development of the specific microbe. Those in whose stomach or intestines there were bacteria which favored the development of the cholera bacillus became affected with cholera, while those in whose system the antidotal bacteria were to be found remained immune. Professor Metschnikoff added that he had thus succeeded in provoking cholera in animals which had hitherto been thought to be immune.

The Section on State Hygiene, which was presided over by Professor Kratter, of Graz, formulated the following unanimous resolutions with reference to cremation:

1. The least dangerous and most rapid, and at the same time cheapest, method of disposal of dead bodies is cremation.

2. Cremation is the best substitute for suitable cemeteries where these are wanting.

3. Cremation is of the greatest importance for the welfare of peoples in times of epidemics.

4. The governments of the various countries must be invited to permit of a facultative legal cremation, and thus provide for an excellent means of prophylaxis against epidemics.

In the first section of hygiene Professor Hans Buchner, of Munich, delivered a lecture on the subject of immunity and immunization, in which he arrived at the following conclusions:

1. The natural power of resisting infections, the so-called "natural immunity," is due to quite different conditions and causes than the artificial or acquired immunity. Both are conditions which *in principio* differ from each other, and which must scientifically be separately considered and inquired into, though, practically, they may occur simultaneously in the same individual.

2. The natural power of resistance is due, on the one hand, to the bactericidal influence of certain dissolved constituents of the organism, the so-called "alexines," and, on the other hand, to a congenital power of resistance of the tissues and the cells of the body against bacterial poisons. This natural power of resistance cannot, as a rule, be conferred through the blood on other organisms.

3. The leucocytes play an important part among the natural means of protection of the organism, but they do not do so through their virtue as phagocytes, but only by means of dissolved substances which they secrete. Phagocytosis is only a secondary appearance.

4. The immunity which is artificially produced, or which is acquired later in life, is due to the presence of modified specific bacterial products, which have become deprived of their poisonous influence — the so-called "antitoxines;" these are to be found either in the blood or in the tissues of the body, or in both. The antitoxines, and also the immunity produced by their action, can be transmitted by means of the blood or the milk.

5. The effect of the antitoxines is not due to direct destruction of the specific bacterial poisons by mutual contact. The effect is only produced within the body, and by means of the same, as the faculty of the living parts of the body to resist the specific poisons becomes thus increased.

Dr. I. Polak, of Warsaw, read a paper on "The Relation between Typhoid Fever and Drinking-water." He presented tables of the mortality in Warsaw since 1877, which showed that among the infectious diseases, such as small pox, measles, scarlet fever, typhoid, typhus, diphtheria, and croup, the mortality from typhoid fever had considerably diminished since 1887, when the new water-works were established in that city, and new measures for sewage were adopted. During the period from 1879 to 1886 the mortality from typhoid fever in Warsaw amounted to from 60 to 105 deaths in 100,000 inhabitants, whereas in the period from 1887 to 1893, it only amounted to from 18 to 30 deaths. Another table which Dr. Polak showed related to gastro enteritis, pneumonia, phthisis, and bronchitis. In this case the regular decrease in the mortality from pulmonary phthisis and bronchitis was also alleged as being the result of the better conditions of the drinking-water in that city.

The festivities before and during the Congress were numerous and brilliant, and gave convincing proof of the Hungarian hospitality.

IS MALARIA A WATER BORNE DISEASE?

To the Editor of the Medical Record.

Sir: I wish to add my experience and observation to the line of inquiry pursued by Dr. W. H. Daly, of Pittsburg, Pa., in his most excellent paper in the Medical Record of September 15, 1894 regarding malarial infection. In the summer of 1881, while employed under the directions of Major G. J. Lydecker, U. S. A., in the construction of the Kampsville Lock (Illinois River Improvement), Kampsville, Calhoun Co., Ill., I had occasion to observe the effects of drinking-water on persons temporarily residing in this malarial district, as well as upon the native inhabitants. The land immediately adjacent to the lock site, was known as bottom-land—it was overflowed at each high water season — and was poorly drained, being very flat. Water stood in the bogs or swamps until the dry weather of summer had completely evaporated it. Drinking-water was obtained for the men employed in the construction of the lock foundation from drive-wells, put down to the depth of about twelve or fifteen feet. The men employed on the dredge and tow-boats, and the officers, used filtered river-water.

Among the many laborers who sought employment were forty Swedes, who had arrived in this country, from their native land, about ten days before coming to the lock; they were a vigorous, well nourished body of men, eager for work. They took board in quarters near the lock, and drank water from the drive-well. Within ten days one of them was taken down with malaria, and before two weeks had elapsed ten or more had succumbed; one died and two were seriously ill. At the end of a month but three were able to continue work; one of these had no malarial symptoms at all; he worked on one of the boats, where he also lived; he drank filtered river water. Now all of these men seemed peculiarly susceptible to malarial infection, and as quickly as they could returned to Chicago to escape its ravages. The men who worked on the boats escaped the disease. The natives who drank of the well-water were not so much affected, yet quite a number of them had to quit work. The wells used by the natives, however, were located on the edge of the bluffs, about one-half mile from the river. Here we have, I think, marked evidence of the infection coming from drinking-water; for all the employees, officers and all, were situated under like atmospheric conditions, and exposed to the same heat, etc., during the day, yet those who used river-water escaped while those using drive or open well-water were afflicted. Some three and one half years spent in engineering work on the Illinois River confirmed my belief in the possibilities of infection from water-supply rather than from atmospheric conditions.

I endorse Dr. Daly's views,

Frank P. Norbury, M.D.

Jacksonville, Ill.

IS IT TIME TO CALL A HALT?

To the Editor of the Medical Record.

Sir: It is a continual surprise to me the indifference of many oculists about the accurate adjustment of glasses. Many jewelry stores have professional refractionists, and a widely circulated jewelry monthly devotes several columns each issue to the instruction and answering absurd queries from men in stores who fit glasses. I know reputable physicians who send patients to these stores because they get better work done than some oculists do. Isn't it about time more attention was paid to accurate refractive work, or are we to lose sight of this in the chase after some *ignis fatuus* like trifling muscular defects.

The phoria craze has reached the stage where conservative men are met with pitying smiles if they venture to suggest that some cases of asthenopia can be relieved by proper glasses. The last two days of the Pan-American Congress the ophthalmological section was in the hands of the phoria men, who pounded the table in their enthusiasm concerning wholesale muscle-cutting. They stated that many operations were often necessary, and admitted that the result was not invariably satisfactory. Their ideas about glasses were inferred when a well-known disciple said that a weak myopic lens should be given the patient if it seemed comfortable, no matter whether the victim was myopic or hyperopic.

No one denies that muscular insufficiency occasionally calls for operation, but it is a pity to lose sight of the good that can be accomplished by proper glasses. If one eye sees as well as the other, if both are equally relieved of strain, then the glasses are right, and the muscles will adjust themselves in the majority of cases. Such being a fact, which would seem more sensible, fit the eyes properly, or hack the muscles forty times with no assurance but that another forty may be necessary.

Richard H. Satterlee, M.D.

THE ANTIDOTAL ACTION OF POTASSIUM PERMANGANATE IN OPIUM POISONING.

To the Editor of the Medical Record.

Sir: In your issue of September 15th I notice an article by Dr. C. Monroe McGuire, under the heading "Unsuccessful Employment of Potassium Permanganate in a Case of Morphine Poisoning," and in justice to Dr. Moor (the original claimant to the discovery of this antidote), who no doubt has become very tired of answering uncalled-for questions and criticisms upon a subject which has been very carefully explained, and by himself and others successfully operated, I would suggest that Dr. McGuire read Dr. Moor's original article in order to understand that his (Dr. Moor's) representations can in no way be called a failure as an antidote in the case he mentions.

It struck me at the time that Dr. Moor had very plainly and concisely pointed out to his medical brethren that after the ingestion of morphia in lethal doses, the administration of potassium permanganate would chemically oxidize and render inert the amount of the poison still in the stomach at the time of the administration; in other words, the part of the morphine with which it comes in direct contact. He does not claim that it has any other effect, and his best proof of the efficacy of the drug as a local antidote was his experimentations upon himself, which prove his absolute faith, which I think no one will question, and again, other prominent medical men have had very successful results from its use.

How are physiological or pathological effects of a drug to be determined except by such methods?

Many of our most important discoveries have been understood only by such means and accident, and I do not think Dr. Moor's results should be denied and decried until good grounds are had for so doing; and particularly upon the grounds given in Dr. McGuire's article, where the stomach had been relieved of every particle of the poison, both by emesis and into the circulation, previous to the administration of the permanganate. So what I cannot understand is, why permanganate should have been given at all in the case mentioned, for it is not claimed to be a physiological antidote, and at that time there was no use for a chemical action.

Under the circumstances I do not see why Dr. McGuire should have been surprised at a depressing effect upon a stomach and system so weakened by emetics and physiological antidotes, and in which there was no morphine.

Clarence Warfield, M.D.

THE MARRIAGE OF SYPHILITICS.

To the Editor of the Medical Record.

Sir: For the purpose of securing reliable statistics on the subject of the marriage of syphilitics, I desire to enlist the assistance of those of your readers who have had experience which will be of value in determining the period when this disease ceases to be communicable and inheritable. I shall, therefore, esteem it a great favor on the part of any physician who will send me answers to the following questions, and due credit will be given in a future publication to those who desire to aid me in this work.

1. What is the latest period, from the date of the initial lesion, that you have known the disease to be communicated by a patient who has been from the first under your observation?

2. What is the latest period, from the date of the initial lesion, that you have known (*a*) a syphilitic man, or (*b*) a syphilitic woman to become the parent of a syphilitic child?

3. Have you ever known syphilis to be either communicated or handed down, at a later period than four years from the date of the initial lesion, by an individual who has been constantly under your observation during that time?

In answering these questions I should like a brief but complete history of each case and an account of the treatment that has been pursued.

I hope by this means to obtain the experience of a large number of observers, and to reach a fairly reliable conclusion as to the time when we may safely permit our syphilitic patients to marry.

Yours very truly,

Burnside Foster, M.D.

Medical Items.

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 29, 1894.

	Cases.	Deaths.
Tuberculosis	135	83
Typhoid fever	33	10
Scarlet fever	21	2
Cerebro-spinal meningitis	2	2
Measles	8	2
Diphtheria	87	31
Small-pox	6	2

Mr. W. Salmon is the oldest member in years, as well as by appointment, of the Royal College of Surgeons of England. He was born in 1790, and was admitted to the College in 1809.

Myxœdema.—Dr. G. P. Marner, of Marion, Kan., in a paper read before the Kansas State Medical Society, on May 4, 1894, reports a case of myxœdema successfully treated with thyroid extracts. The patient was a married woman, aged thirty-eight, in whom the first symptoms appeared about ten years ago. The disease had progressed slowly but steadily. Treatment was begun on New Year's Day with the exhibition of a five-grain powder every day. From the beginning of the treatment she improved rapidly, and on April 28th was apparently cured. Her weight had decreased in four months from one hundred and seventy to one hundred and fifty pounds, and the transformation in her general appearance was so great that her most intimate friends scarcely recognized her.

Longevity in Russia.—In the province of Kieff, during 1893, there were fourteen deaths of persons over one hundred years of age. In the city of Kieff one man died aged one hundred and ten years, while within the suburban circle two women died aged respectively one hundred and two and one hundred and four years. In Berditcheff two men reached the ages of one hundred and one and one hundred and fourteen years respectively. In Vassilkoff another died in his one hundred and fifteenth year. In the same district there died a woman aged one hundred and five; in Svenigorodka, a man of one hundred and ten years; in Tarastscha, another one hundred and fifteen; in Uman, two men, aged respectively one hundred and six and one hundred and two years; in Radomytzel, two aged respectively one hundred and three and one hundred and seven; and lastly a man of one hundred and five years died at Tcherkassy. The united ages of these fourteen persons amounted to 1,489 years. A man is still living in Saratoff who has already celebrated 126 birthdays.

A Missionary to Lepers in Trouble.—Miss Kate Marsden, who achieved some notoriety some years ago as a missionary to the Siberian lepers, was recently accused of acts unbecoming a missionary. The charges were investigated by a committee in St. Petersburg, with the result that Miss Marsden has been called upon to give up, in accordance with a promise made at the beginning of the investigation, all decorations, letters, etc., bestowed upon her by royal and imperial well-wishers.

THE NECESSITY OF INTERNATIONAL SANITARY REGULATIONS GOVERNING THE MIGRATION OF LARGE BODIES OF PEOPLE IN THE PREVENTION OF THE SPREAD OF CONTAGIOUS AND EPIDEMIC DISEASES.

ILLUSTRATED BY THE INTERNATIONAL SANITARY CONFERENCE OF PARIS, 1894 [1]

BY STEPHEN SMITH, M.D.,

NEW YORK.

THOSE diseases which are classified as contagious and infectious are the common enemies of mankind. Every human being inherits a predisposition to these affections. No one, therefore, is exempt from an attack, on proper exposure, by reason of nationality, civilization, rank, or condition. In their spread these pestilences have no regard for the lines which bound nations, but wherever man finds his home there they find a congenial soil for propagation.

The influence of these diseases upon the history of our race has always been disastrous. They have proved more fatal to human life than all other causes combined; they have destroyed the armies of conquerors whom no earthly power could resist; they have, indeed, obliterated from the earth, as by an omnipotent force, whole races of mankind. They have often given the death-blow to an advanced civilization, or have left a strange enduring impress on the intellectual life of great nations. The historian states that among the causes which brought about the fall of the might and civilization of Greece and Rome must be mentioned destructive pestilences which swept over the Eastern and Western Roman Empire during the period between antiquity and the Middle Ages (Ziemssen).

The problem of preventing and suppressing these scourges of the race has been studied exhaustively in ancient and modern times, but with very different degrees of success. To the ancient student their origin remained a mystery which no means at his command could penetrate. With all his research he could discover neither their causes nor the laws governing their propagation. One solitary fact of vast importance was impressed upon his mind by the abundant opportunities for observation, viz., that complete non-intercourse of the sick, and his personal effects, with the well was a reliable means of protection and prevention. Hence came the famous institution of quarantine, or forty days' isolation of vessels from infected ports, a period believed to be sufficiently long for the destruction of the contagium. Its true significance was non-intercourse of the sick with the well. This was, indeed, the only means by which a city could at that time protect itself from an invasion of the pestilence. And even now cities and states, when left to their own individual resources against epidemic diseases, find quarantine the most effective measure which they can adopt. It is true that the quarantine of to day differs greatly from the quarantine of the past. Formerly, time was the chief feature relied on to destroy the contagious principle, and hence the period of detention was of long duration. Now, detention is enforced only during the period necessary for the destruction of the contagium by germicides, or of the incubation of the germs of disease. Still, quarantine means the detention of the traveller and his effects, and of articles of commerce liable to convey infection.

Though the rigors of the ancient quarantine have been relaxed, it was not until within the last decade that there began to be a clear conception of a method of substituting for them measures far more effective, and comparatively free from inconvenience, either to traveller or to commerce. This was the co operation of the states exposed to the epidemic in well-concerted measures against a common enemy.

The first step toward international action in regard to public sanitation and maritime quarantine was taken, in 1847, by the French Government, which has always been foremost among the nations of Europe in advancing sanitary science. Preliminary to the calling of an International Sanitary Conference, she appointed medical sanitary agents in the East. The posts of observation thus created were at Constantinople, Smyrna, Beirut, Alexandria, Cairo, and Damascus. The information in regard to sanitary conditions in those cities derived from these sources formed the basis for the Conference of Paris, which was convened on invitation from the French Government in 1851. Twelve powers were represented by delegates at this conference. The results obtained were, a relaxation of the rigor of quarantine in Mediterranean ports, and a scheme of rational maritime prophylaxis.

Thus was inaugurated international hygiene, a system of sanitatary administration which seems destined to control, suppress, and finally exterminate contagious and infectious diseases.

Nine International Sanitary Conferences have since been called, and six have been held. The earlier Conferences were not fruitful of immediate results. The field of labor was new and unexplored, and diplomatic questions arose which greatly interfered with that harmony of action of states essential to success. The discussions of representatives of different states, did, however, improve the sanitary administration of each. But their greatest value appeared in the better understanding which the states of Europe came to have of the aims and purposes of each other when discussing measures of prevention against a common enemy. Mutual confidence was in a measure established, which led to far more effective work in future Conferences. This was apparent in the Conference of Venice, the seventh in the series, held in 1892, which was called to consider the means of preventing direct communication between Europe and the infected regions of India, by way of Egypt and the Mediterranean ports. The Conference succeeded, first, in regulating the duration and method of quarantine in the Suez Canal; second, in preventing the passage through the Canal of infected vessels; third, in requiring disinfection of suspected vessels; fourth, in creating the Council of Alexandria, with a preponderance of European influence.

The resolutions adopted by the Conference were embodied in an agreement which was signed by the plenipotentiaries and afterward ratified by the powers represented — the first formulated conclusions of any Conference made authoritative by the signatures of the plenipotentiaries.

Still greater progress was made toward the creation of

[1] Read at the Annual Meeting of the New York Medical Association, October 10, 1894.

international laws by the Eighth Sanitary Conference, which met at Dresden, March, 1893. The programme proposed for consideration the following subjects:

1. The duty of a Government when cholera is reported within its territory.

2. The measures to be taken when cholera exists in a neighboring country.

The Conference decided that the declaration of the presence of contagious diseases is obligatory, and that every means should be taken to prevent its spread. It formulated a system of sanitary measures which afforded a maximum of protection for public health with a minimum of restriction to travel and traffic; it fixed the period of detention and isolation; it defined the distinction between medical surveillance and observation; and finally it permitted a person arriving from an infected port to proceed to his destination, but it maintained a rigid observation of him during the period of incubation of the cholera germ. The resolutions of this Conference were followed by a convention which was signed, with but one or two exceptions, by all of the powers represented.

These last two Conferences proved conclusively that international agreements could be made designed to prevent an invasion of Europe by cholera, which, though placing severe restrictions upon commerce and travel, were not incompatible with the laws and customs of the contracting powers. But valuable as these agreements might prove to be, they were simply barriers erected around the immediate frontier of the state against a foe whose habitat was in the far distant delta of the Ganges. Modern science has proved conclusively that the germs of this plague have never left their native soil except when they were conveyed by human agency. Repeated epidemics had also demonstrated the fact that cholera never invaded the districts of Northern and Western Asia except when large bodies of people made pilgrimages to the holy places of the Orient. The chief and most important of these pilgrimages was that to Mecca by the pilgrims of India. It was equally demonstrated by repeated observations that cholera reached Europe only through its pilgrims who visited the holy places of Asia, and especially Mecca. It became, therefore, a well-established fact that the transmission of the cholera infection from India to Europe was, in its first stage, through the pilgrimages of the Mussulmans from India to Mecca, and other places of resort. At these places it was transferred to the European pilgrim, who conveyed it to Europe. It was evident that the international rules and laws enacted did not meet existing conditions. As a matter of fact, cholera appeared at Mecca eight times between 1871 and 1893. The European states, therefore, could not be certainly protected when the cholera infection was brought without hindrance to Mecca, and the European pilgrim was allowed to visit Mecca and return without any proper sanitary surveillance.

Such considerations as these induced the French Government, always alert in its efforts to provide adequate measures for the prevention of cholera epidemics, to issue a call for another Conference, the ninth in the series, and the fourth called by the Government of France. The object of this Conference was to provide measures for preventing, by international agreements, the transmission of cholera from its native habitat by pilgrims. The task was the greatest and most important ever undertaken by any state or combination of states.

This Ninth Conference met in Paris, on February 7, 1894, and was attended by representatives from sixteen states, viz., all the powers of Europe except Switzerland; and Persia, and the United States, Egypt, the British possessions in India, and the Straits Settlements of the Netherlands.

In his opening address the President of the Conference, M. Casimir Perier, now President of the French republic, eloquently portrayed the duties of the assembled delegations. "The modern scientific spirit," he remarked, "has proved both its firmness and its flexibility in the course of extended efforts to combat the Asiatic pestilence by means of international agreement. By more exact information of the disease and the phenomena attending its transmission, it has gained a knowledge of prophylactic measures both more certain and more prompt. It has demonstrated that the more simple methods are at the same time the more efficacious. It has conserved public interest at the same time that it has protected human lives. The connections which diplomacy has had the honor of concluding have been matured in the laboratories where men of science pursue their disinterested researches. It is the common labor and the common honor of science and diplomacy to acquire and exercise the knowledge necessary to reconcile the customs which govern international commerce and the laws on which depend the protection of human life. . . . You have to continue now the labors which were commenced at Venice. It is your duty to pursue cholera toward its source; toward that part of Central Asia where it is said to have its origin so far as it affects us. This part of your task is particularly delicate, and the method and the principles which have heretofore guided you should again govern your actions. They are now recognized as correct, and they have hence acquired a high authority. But in applying them you should not forget that sympathy for those who suffer, individual kindness, and international fellowship, generosity and equity, ought also to have their proper place in your deliberations. It is in these previous deliberations that you will have found the discretion necessary to unite to all of the guarantees that health and the public interests may require, respect for local customs, usages, and traditions, and especially that persuasive influence which shall secure to your decisions the concurrence of all upon whom they ought to be binding."

M. Barrère, the acting President, after explaining at some length the events which led to the present Conference, introduced Professor Proust, who read an elaborate paper, in which, after reviewing the work of preceding Conferences, showing how effectually they had protected the immediate approaches to Europe from an invasion of cholera, he proceeded to detail the questions which the present Conference was called to consider. They involved problems more difficult of solution than any ever presented to a deliberative body. The danger to Europe from an epidemic of cholera, primarily, depends upon the periodical migration of large bodies of the Mussulmans from India, the natural habitat of the cholera germ, to the holy places of Northwestern Asia, and especially to Mecca. Cholera has never visited Europe except when transported from the delta of the Ganges by pilgrims. These pilgrimages are made by vast hordes of people, the greater number of whom are poor and feeble, or actually sick, and all are accustomed to filthy habits. It appears that sixty per cent. of those who leave India on these pilgrimages never return to their homes. The problem of preventing epidemics of cholera in Europe could only be solved by subjecting these pilgrims to rigid sanitary regulations, and to effectually accomplish this object there must be international agreements.

The difficulties to be encountered in adopting and enforcing sanitary rules for pilgrims were numerous. 1. The pilgrims themselves would be intolerant of any restrictions upon their performance of a religious obligation. 2. Sanitary regulations adequate to prevent the transportation of cholera infection must in some degree interfere with the ordinary freedom of commerce. 3. These sanitary rules and regulations, in order to be effective, must be enforced under the supervision of a central authority and not by local authority.

It was very evident, therefore, that this Conference was confronted with difficulties which no other had to encounter. While it might prove an easy task for the technical delegates to formulate an ideal code of sanitary rules which, if rigidly enforced, would effectually prevent the transportation of cholera by the pilgrims, it

was apparent that the diplomatic delegates would have no slight difficulty in reconciling the various commercial and public interests involved.

It will forever redound to the credit of this Conference that it resolutely set to work on the programme laid before it, and not only created a body of admirable sanitary rules governing pilgrimages, but provided adequate means of enforcing them.

The programme presented by the French delegation was as follows: [1]

I. Prophylaxis of the Pilgrimage of Mecca.
II. Protection of the Persian Gulf ports.

The programme of discussion was formulated as follows:

I.—Prophylaxis of the Pilgrimage to Mecca.

(*A*) Sanitary police in Indian ports.
1. Medical inspection of pilgrims.
2. Disinfection.
3. Refusal of embarkation of infected or suspected persons.
4. Refusal of embarkation to all pilgrims who shall fail to show that they possess means to defray the expense of the pilgrimage; five days' observation of other pilgrims.
5. Sanitary passport.
6. Disinfecting apparatus on each vessel.
7. Adequate supply of potable water protected from infection.

(*B*) Sanitary surveillance of pilgrims at the entrance of the Red Sea.
1. Choice of site for quarantine station.
2. If Camaran be chosen, improvements to be instituted.
3. Disinfecting apparatus.
4. Formation of board of management to be under the control of the Sanitary Council of Constantinople.

(*C*) Improvements to be instituted at Abou-Saad and Vasta.
(*D*) Supervision of land caravans of pilgrims to Mecca.
(*E*) Reorganization of the sanitary station of El Tor.

II.—Protection of the Persian Gulf ports.

(*A*) Establishment of sanitary posts at Fao, Bender-Abbas, Koveit, Bender-Bouchir, Bassorah, Mohammerah.
(*B*) Sanitary surveillance at Menama, in the Bahrem group of islands.
(*C*) Sanitary supervision at Mascate and Guadar, in Beloochistan.
(*D*) Constitution of a sanitary authority to have charge of carrying out quarantine measures.

A wide divergence of views, in regard to the best method of treating an epidemic of cholera very early appeared among the technical delegates, and became very pronounced in the discussion of many questions throughout the entire session. These different opinions were as follows:

1. The French delegates held that cholera infection should not be allowed to be conveyed from place to place, either by travellers and their effects or by articles of commerce, hence they approved of enforcing such sanitary rules as would free the traveller and his baggage, as well as articles of commerce, of the contagion of cholera at any place in their transit where they were discovered or suspected to exist. This policy was sustained by every delegation except that representing Great Britain and its dependencies.

2d. The British delegation held that the proper method of dealing with cholera is to perfect the sanitary conditions of cities, villages, and the homes of the people, and allow the contagium of the pestilence free course along the routes of travel, whether by sea or land. All barriers to the entrance of cholera into any state were condemned, especially any form of quarantine which delayed the progress of vessels into ports and the immediate discharge of cargo. This public policy was supported only by the delegation from Great Britain.

3d. The delegate who represented the British possessions in India held that cholera is due to epidemic influences quite beyond human control; hence he advocated non inteference. This policy was supported only by the delegate who represented India.

The scope and character of the regulations adopted can be illustrated by a few selections. In general it may be stated that the pilgrim is placed under sanitary surveillance of a very rigorous character from the moment he announces his intention to go on a pilgrimage, till his return home. 1st, He must obtain a sanitary pass port from the local authority. This rule is taken from the Netherlands' Straits Possessions. Before the passport is issued, the intending pilgrim must prove that he has complied with all of the conditions necessary for his departure; and that he has money sufficient for the voyage, and to sustain his family in his absence. This passport the pilgrim must retain and show to the sanitary authorities, *en route*, and he can enter the Hedjaz, the province in which Mecca is located, only on presentation of it, and on passing an examination. He is under sanitary observation while at Mecca, and on his return a new passport is given him, which he must show to the authorities *en route*.

At the port of departure the pilgrim comes under the sanitary police, and the following regulations are to be enforced:

Medical inspection of all persons taking passage on board a pilgrim vessel made individually, by daylight, on land, and by a physician appointed by the local sanitary authority.

Thorough disinfection made on land under the direction of the physician appointed by the sanitary authority of all infected or suspected articles.

Refusal of embarkation to any person attacked with cholera or choleriform disorders.

When a case of cholera exists at the port, embarkation on board of pilgrim vessels shall not take place until the persons to be embarked have been segregated and subjected to observation for five days.

Each pilgrim vessel must have the following provisions:

Every vessel embarking one hundred or more pilgrims shall carry a physician commissioned by the government to which the vessel belongs. If the number of passengers exceeds one thousand a second physician shall be engaged.

The physician should see that the rules of hygiene are observed on board, and that food and water are distributed according to agreement.

Pilgrims shall be lodged between decks.

The deck should remain clear. It should be placed at the disposal of the passengers.

Passengers shall be allowed to retain only such baggage as is strictly necessary.

The vessel shall be provided with latrines in the proportion of one to each one hundred passengers. These shall not be located in the hold or between decks. They shall be cleaned three times daily and flushed with sea water.

Each person shall be gratuitously furnished with five litres of drinking-water a day.

If there shall arise any doubt as to the condition of the drinking-water it should be boiled and sterilized, and the captain is directed to empty it overboard and replenish at the first stopping-place.

Two kitchens shall be provided for the use of the pilgrims. They shall not be allowed to cook elsewhere.

Medical care and attendance shall be furnished gratuitously to the pilgrims.

A regularly organized infirmary shall be provided for the sick. It shall be large enough to accommodate five per cent. of the passengers, with a space of three square metres per capita.

The vessel shall be provided with the means of isolation in case of choleraic attack.

Each pilgrim vessel is subjected to the following regulations at the port of departure:

The captain of a pilgrim vessel is required to declare to the port authority, at least three days in advance, his intention of embarking pilgrims. He must also declare the date of intended departure and the port of destination.

The sanitary authority of the port shall then inspect and measure the vessel. The consul representing the flag carried by the ship may assist, if he so desires, at this inspection.

The port authority shall not permit the departure of a vessel until he is assured:

(*a*) That the vessel is clean, and, if possible, disinfected.

(*b*) That it is in condition to undertake the voyage, and that the sanitary conditions are good.

(*c*) That the food and fuel provided for crew and passengers are sufficient in quantity and good in quality.

(*d*) That the water is good and obtained from a pure source; that it is sufficient in quantity, protected from contamination on board, and dispensed by faucets.

(*e*, *f*, *g*, *h*) That the vessel carries distilling apparatus capable of producing five litres of water a day per capita for all persons on board, passengers and crew; that it carries a disinfecting stove and has on board a physician and a ship's medicine-chest, and that the deck is clear.

The captain shall post notices drawn up in the principal languages spoken by the pilgrims stating:

[1] See Abstract of Sanitary Reports issued by the U. S. Marine Hospital Service for Summary of Conference proceedings.

1. Destination of the ship.
2. Daily ration of food and water.
3. The price of provisions not included in the daily distribution.

The captain shall not be free to leave port until he holds:

1. A list of the pilgrims whom he is authorized to embark, viséd by the port sanitary authority.

2. A bill of health stating the name, nationality, and tonnage of the vessel, name of the captain and physician, the number of persons embarked, crew, passengers, and pilgrims, nature of the cargo, place of departure and destination, and condition of public health in the port of departure.

During the voyage the following requirements are enforced:

All articles that have come in contact with the sick shall be promptly disinfected. Articles of no value should be thown overboard if the vessel is at sea, or else burned if the vessel is at port.

In case of a death occurring on board during the voyage the captain shall note the fact with all particulars.

The bill received at the port of departure shall not be altered in any way during the voyage. It shall be viséd in every port at which the vessel stops by the sanitary authority who shall note thereon:

The number of passengers landed or embarked.

Any facts touching the condition of the passengers and any incidents of the voyage.

The sanitary condition of the port at which the vessel is stopping.

The captain shall see that all prophylactic measures taken on board during the voyage are inscribed in the log.

The captain shall pay all sanitary taxes.

Arriving at the Red Sea, and before proceeding to Hedjaz, the pilgrim ship must touch at the sanitary station at Camaran and there be subject to the following treatment:

Vessels declared upon medical inspection to be clean shall be allowed free pratique after compliance with the following regulations: The pilgrims shall be disembarked; they shall take a spray bath or a bath in the sea; their soiled linen and such of their baggage and effects as may be suspected of infection shall be disinfected. The duration of this process, including landing and re-embarkation, shall not exceed forty-eight hours. If during this period no case of cholera, diarrhœa, or choleriform disorder shall develop, the pilgrims shall be at once re-embarked and the vessel shall proceed to the Hedjaz.

Suspected vessels—that is to say, vessels on board of which cholera declared itself at the moment of departure, but on which no new case has occurred within seven days—shall be treated as follows: The pilgrims shall be disembarked; they shall take a spray bath, or else a bath in the sea; their soiled linen and such of their baggage and effects as may be suspected of infection shall be disinfected, at the discretion of the medical officer. The duration of this process, including landing and re-embarkation, shall not exceed forty-eight hours. If no case of cholera or choleriform disorder shall develop during this period, the pilgrims shall be at once re embarked, and the vessel shall proceed to Djeddah where a second medical inspection shall be made on board. If the result is favorable, on the written and certified declaration under oath that no case of cholera has occurred during the voyage from Camaran, the pilgrims shall be disembarked. If, on the contrary, cholera or choleriform disorder shall have declared itself during the voyage, or at the moment of arrival, the vessel shall be remanded to Camaran, and there undergo a second time the treatment for infected vessels.

Infected vessels—that is to say, vessels on board of which cholera and choleriform disorder shall have declared itself within seven days—shall be treated as follows: The persons attacked with cholera or choleriform affections shall be disembarked and isolated in hospital. Thorough disinfection shall be performed. The other passengers shall be disembarked and isolated in groups, consisting each of as few persons as possible, in order that only a small front shall be exposed to choleraic attack, should the disease develop. The soiled linen, utensils, and clothing of crew and passengers shall be disinfected; also the vessel itself.

The sanitary authorities shall decide whether the unloading of the larger baggage and the cargo is necessary, and whether the entire vessel or only a portion of it shall be disinfected.

The passengers shall remain five days at Camaran. If the cases of cholera date back for several days, the period of isolation may be curtailed. It shall vary according to the date of the last outbreak and in the discretion of the sanitary authority.

From Camaran the vessel shall proceed to Djeddah, where thorough medical inspection shall be made on board. If the result is favorable the pilgrims shall be disembarked. If, on the contrary, cholera or choleriform disorder shall have developed on board, either at the moment of arrival or during the voyage from Camaran, the vessel shall be remanded to Camaran, and shall there undergo for a second time the treatment for infected vessels.

Such is but a summary of the rules made by the Conference governing the pilgrimages from India by way of the Red Sea. Similar rules were made to apply to pilgrims going by way of the Persian Gulf, or approaching Hedjaz from the north. These rules were to be equally enforced on the return of the pilgrims to their homes by any route. While at Mecca the pilgrims were under rigorous sanitary surveillance.

An examination of these rules will make it apparent that if they are rigidly enforced cholera cannot reach Europe again through the medium of Mussulman pilgrimages. And herein we have the possible failure of the work of the Conference. Sanitary rules are worthless if not faithfully executed, and yet no class of laws is so difficult of enforcement as those designed to protect the public health.

In their practical application, to be effective in the prevention or control of contagious and infectious diseases, individual rights, religious observances, commercial interests, and even national customs, must be subordinated to the exigencies which these pestilences create.

It has been held that health laws are anomalies in civilized government. They arbitrarily set aside ordinary laws because they are adapted to an anomalous condition of the people. When it is considered that the health laws created by the Conference were to be applied to people intolerant of any restriction upon individual liberty, and especially upon the customary performance of ancient religious obligations, it will be apparent that when the technical delegates had perfected their work of completing the rules and regulations, a serious responsibility was imposed upon the diplomatic delegates in providing the ways and means for their execution.

There was a strong disposition manifested by those states within whose jurisdiction these rules were to be chiefly executed, to be alone responsible for their enforcement. But the other states very properly opposed such action, alleging that local interests might interfere with that rigid execution of every necessary detail so essential to success. A failure of one state through which the pilgrims might pass, to rigorously apply the rules, would imperil the entire scheme. It was determined, therefore, after much discussion, that all of the contracting powers should have a part in the enforcement of these international agreements. The following method of accomplishing this object was finally agreed upon:

1. The application of the measures adopted by the Conference in regard to the pilgrimages shall be intrusted to a committee chosen from among the members of the Council of Health of Constantinople. This committee shall be composed of three representatives of Turkey and of the several powers who accepted the sanitary agreement signed by the Conferences of Venice and Dresden. The president of the committee shall be an Ottoman.

2. To secure effective service at the several sanitary stations, competent corps of physicians, disinfectors, mechanics, and sanitary guards, recruited from among ex-officers, commissioned and non-commissioned, shall be created.

3. The expense of carrying out the system proposed by the Conference shall be divided between the Ottoman Government and the Council of Constantinople, according to the scale already fixed by the several powers interested.

4. The sanitary authority at the Ottoman port of arrival or departure shall draw up a statement of any infraction of this agreement, to which the captain of the offending vessel shall attach any explanation he may have to make. A certified copy of this statement shall be transmitted to the consul representing the country to which the vessel belongs. The consul shall require the fine to be placed in his hands. In the absence of the consul the fine shall be deposited with the sanitary authority. The fine shall ultimately go to the Council of Constantinople, when the consular commission shall have declared it valid. A second certified copy of the statement shall be forwarded to the Council of Constantinople, who shall refer it to the consular commission.

5. A consular commission shall be formed at Constantinople to have cognizance of disputed cases, and to act as judge between the

sanitary agent and the ships' captains. It shall be elected every year.

6. The taxes and sanitary fines shall not be diverted to any objects but those relating to the sanitary councils.

In addition to these regulations the Conference provided for the equipment of suitable stations on the route of the pilgrims, with all the apparatus necessary to make each a sanitarium, where the traveller will receive the most perfect sanitary care and treatment. The Ottoman Government had already created several stations, and the Conference took measures to perfect them and add others. Thus the island of Camaran, near the entrance to the Red Sea, it recommended should be entirely devoted to a sanitarium for the pilgrims coming from the south. For this purpose all the present inhabitants are to be removed, the harbor is to be rendered secure to shipping, and every facility supplied for the comfort of passengers, and the thorough cleansing and disinfection of themselves, their effects, and the pilgrim ships. In the same manner, Djebel-Tor, at the northern extremity of the Red Sea, is to be provided as a sanitarium for the pilgrims from the north. The ports of the Hedjaz, where the pilgrims debark for Mecca, are to be equally well equipped as sanitary stations. A large number of similar sanitary stations will be created along the Persian Gulf route, and also along the overland caravan routes. Finally, Mecca is to have its sanitary conditions perfected, and a complete surveillance of the pilgrims organized.

For nearly two months the Conference devoted itself assiduously to its duties. It was aided and encouraged in its work by the highest officials of the French Government. President Carnot frequently met the delegates; M. Casimir Perier, the Premier, accepted its presidency. M. Barrère, now Ambassador to Switzerland; M. Hanotaux, now Minister of Foreign Affairs; Professor Brouardel, Dean of the Faculty of Medicine of Paris; Professor Proust, Inspector-General of the Sanitary Service; and M. Monod, Councillor of State, comprised the French delegation. To the courtesy, constant efforts, and judicious management of this delegation is due in large measure the harmony which characterized the deliberations of the Conference and the happy consummation of its labors.

The code of sanitary rules governing the migration of large bodies of people from or through districts infected with cholera which the Conference finally completed and adopted, is based on the most advanced principles of sanitary science. When this code is finally accepted by the powers of Europe and Asia, and by the United States, and then becomes in effect international law, it will mark the commencement of an era which will be characterized by the extermination of those roving pestilences which have heretofore been the scourge of the human race.

One feature of the Conference remains to be noticed, which is of special interest to the people of the United States. As this Conference was called to devise international measures to prevent the transportation of cholera by the migration of large bodies of people, it seemed to the delegates from the United States, or at least to a majority of them, that it would be a fitting occasion to consider also the closely allied subject of the conveyance of cholera from Europe to the United States by emigrants. It was apparent that the sanitary rules and regulations relating to travel and traffic which would prevent the transmission of the cholera infection from India to Europe by the pilgrim, would, if properly applied, prevent the transmission of cholera from Europe to America by the emigrant. The instructions which the delegates received from their Government led them to believe that the President also entertained the opinion that the question of the transportation of cholera by emigrants would be a legitimate subject of discussion in the Conference.

Actuated by these considerations the delegation brought the matter before the Conference at its third session in a formal paper. It was shown in this statement that cholera has as yet never reached the United States from Europe except through the emigrant classes. The imminent danger of an invasion of the United States by cholera, when it is prevalent in Europe, will appear when we consider:

1st. The vast numbers of immigrants who land on our shores annually. In 1893, 357,857 emigrants from Europe arrived at the single port of New York. In some years the number has been quite half a million.

2d. These immigrants are, for the most part, the poorest, filthiest, and most insanitary class of the population of the states of Europe. They are not only extremely filthy in their persons and habits, but they bring large quantities of filthy baggage and household goods, which are admirably adapted to preserve the germs of contagious and infectious diseases in all their potency.

3d. The rapidity with which the transit of the ocean is now made by the great passenger vessels—and it is on this class of steamers that the bulk of the immigrants reach the port of New York—renders it possible now for an emigrant to receive the cholera into his system in Europe and be safely domiciled in New York City before the period of incubation has fairly expired.

To meet these exigencies the United States has but one remedy, and that is a rigorous quarantine. Such sanitation of cities, villages, and the homes of the people as might make it safe to allow the cholera contagium free access to our ports is impossible. The opinion was expressed that if, by an international agreement, such sanitary regulations could be enforced as would secure to the emigrant from Europe to America cleanliness of person and baggage, adequate means for his care during the voyage, and a reasonable guarantee that he is not the carrier of the cholera germ, would be followed by greatly diminished restrictions, which our Government must otherwise impose upon travel and commerce in our ports.

The communication of the delegates concluded by requesting that the programme of the Conference be so enlarged as to include the preparation of international sanitary rules governing the migration of the laboring classes of Europe to America.

At a subsequent session the United States delegates submitted more in detail, at the request of the Conference, the questions for consideration. The several propositions were nearly those already under discussion in regard to the pilgrims, viz.

1. Measures to be adopted to enable the emigrants to come to the port of departure free from contagious diseases. Each emigrant should obtain from the local authority a passport or certificate showing the sanitary condition of the place from which he came, the route that he has followed to the port of departure, and, as far as possible, the state of his health during his journey. The passport for the pilgrim made nearly the same provision.

2. Measures to be taken at the port of departure to prevent the germs of cholera being taken on board of vessels, either by the emigrants personally, or by their clothing or other effects. These measures would correspond with those adopted by the Conference with reference to pilgrims at the port of departure, viz., detention for several days in reception quarters where bathing and disinfection could be thoroughly performed and any infection present destroyed.

3. Measures to be taken to secure the best sanitary condition of vessels carrying emigrants, before their embarkation, in order that the health of the emigrants may be preserved during the voyage. The excellent sanitary regulations which the Conference adopted for pilgrim ships would apply with some modifications to emigrant ships.

4. Measures to be taken during the voyage both to preserve the best sanitary condition of the ship, and of the emigrants and equipage, and to promptly suppress any focus of infection which might develop on board.

These provisions were amply made by the Conference with regard to pilgrim ships during the voyage.

5. Measures to be taken at the port of arrival, which would comprise such changes in the regulations of our quarantines as would adapt them to the new conditions which these international regulations would secure as to the liability of emigrants to be the carriers of cholera infection.

The communication of the American delegates was received with marked attention by the members of the Conference. It was conceded that there was such a close analogy between the methods of conveyance of cholera infection from India to Europe by the pilgrims, and from Europe to America by the emigrants, that the international sanitary regulations governing the migration of one class would be nearly applicable to the other. The delegates of several states cordially adopted the views of the American delegates, and were disposed at once to consult their respective governments to obtain the power to enlarge the programme in accordance with our request. Others, while acknowledging the great importance of the subject, were of the opinion that, as the present Conference was called for a specific purpose, it should not add to its duties another obligation, however closely it might be allied to the one in hand. They proposed that the emigrant question be deferred to another Conference called for that special purpose. The British delegation opposed enlarging the subjects for discussion at the present Conference, and also to the calling of another Conference to consider the emigrant question, basing their objections upon their often-reiterated opinions that the prevention of the spread of cholera should not be attempted by restrictions upon travel and commerce, but that every state should secure to its people homes so healthy that they would defy the potency of the cholera germ. It should be stated that at one of the sessions of the present Conference, on the occasion of the statement of the above opinion by the distinguished medical officer of the Local Government Board of England, the technical or medical delegate of Greece, replied that his Government had no such power as would secure that degree of sanitation of the homes of the people of which the English boast, and it must, therefore, rely upon a rigorous quarantine against cholera. As to the value of home sanitation compared with a rigorous quarantine in the protection of the people against cholera, he reminded the British delegation that during the last year there were several outbreaks of cholera in England, with a number of deaths, while for forty years there had not been an outbreak of cholera in Greece, though the pestilence had many times prevailed in surrounding countries.

After considerable discussion the Conference decided not to change its programme, but with much unanimity concurred in the opinion that another Conference should be called, if requested by the Government of the United States, to formulate international sanitary regulations governing the migration of European populations to America.

Meantime the delegates from several of the powers received instructions to unite in the call of such Conference, and two delegations presented the formal requests of their governments to be permitted to entertain the Conference at their respective capitals. The United States delegation reported the action of the Conference to their Government, and asked for instructions. The President replied that it was too late in the season to call another Conference. Thereupon further efforts to arrange for a Conference were discontinued, but the final sentiments expressed to us by many members were to the effect that, whenever the United States Government signified to the European powers its desire to enter a Conference with them for the purpose of establishing an international agreement relating to the sanitary supervision of emigrants from Europe to America, all of the states invited would respond.

To one who has practically studied the problem of the prevention and suppression of such world-wide epidemics as Asiatic cholera, the importance to the people of the United States of the co operation of the governments of Europe with our Government, in freeing the emigrant from the germs of contagious and infectious diseases before he embarks for our ports, cannot be overestimated. The proposed scheme of sanitary surveillance of the emigrant would begin at his domicile abroad, and follow him every step of the way to his home in this country. His passport issued by the local European health officer, and viséd at every point in his progress, would not only contain a record of his condition as regards his freedom from infection and his health, but it would be his only guarantee that he could travel at all on railways to the port of departure or that he could embark on any steamship bound to a port in the United States It is at once apparent that such an international agreement would bring to our shores only healthy emigrants and in healthy ships. Two consequences would inevitably follow, viz., first cholera would never be brought to this country by the European emigrant; and second, our quarantine would consist only in a detention for the examination of the passports of emigrants and the inquiries and inspections necessary to determine that shipmasters had faithfully complied with the international sanitary regulations.

Thus closed the Ninth International Sanitary Conference, in many respects the most important of the series. It was in fact a congress of nations summoned to create a code of international laws entirely in the interests of human health, and consequently of human happiness. Its sessions were characterized throughout by that earnestness in the discussion of theoretical questions and that conciliation in harmonizing practical methods which distinguishes the modern scientific spirit. We cannot doubt that when the laws which it enacted are faithfully executed, not only will Europe and Northern Asia be relieved from periodical visitations of the most destructive plague of modern times, but that the vast hordes of roving pilgrims which traverse Asia, scattering a pestilence which decimates the people among whom they pass, while it strews their own pathway with their dead, will be transformed to an orderly body of travellers, characterized by that physical and mental health and cleanliness of person and baggage so essential to the rational discharge of religious obligations.

But have not the nations which in this Conference accomplished so great a work in the relief of the Mussulman pilgrim, and the protection of Europe from cholera, a similar duty to perform toward the Western emigrant, who, taking up the germs of the plague brought to Europe, conveys them in his filthy person and effects to America? M. Casimir Perier complimented the delegates to the Ninth International Sanitary Conference on the success which science has had in breaking down those ancient barriers which the varied interests of mankind have created, and urged them to persevere in the good work until all such restrictions are removed. Must there not be a Tenth Conference, which shall unite the efforts of the European powers and the United States in removing the barriers with which commerce and custom protect the emigrant from the application of those sanitary measures which would strip him of every form of contagion, and bring him to our shores in good physical and mental health?

The Prussian Government expends over $50,000 a year in support of the laboratories connected with the medical department of the University of Berlin. This is exclusive of the salaries paid to professors

Asphyxia and Tongue Traction.—Dr. Bories reports, in the *Tribune Médicale*, the case of a child who apparently died during the performance of a tracheotomy for croup. Artificial respiration was of no avail, but life was restored in five minutes by rhythmical tractions of the tongue.

THE PLACE OF PHYSICAL TRAINING IN THE MILITARY SERVICE.

By JAMES E. PILCHER, M.D., Ph.D.,

CAPTAIN IN THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY.

It is an admitted fact that the mortality from disease attains a considerably higher percentage in war than that from wounds. It would seem, then, that the prevention of disease is the most important function of the medical officer in active campaign. In peace, where the mortality of the battle-field is entirely eliminated from consideration, prophylaxis plays a still more important *rôle*. Recognition of the value of careful attention to the suggestions of the medical officer as an important factor in securing the greatest efficiency of a command has been a matter of slow growth, but it has been progressive. The influence upon a command of the sanitary condition of camps, cuisine, and clothing, has come to be fully recognized through the active labors of army medical officers, until the surgeon is no longer considered a useless encumbrance except when sickness is present, but takes his place as the most important member of the staff.

It is singular that, while the medical department has devoted ample attention to the prevention of disease by the removal of threatening conditions, it has almost entirely neglected prophylaxis by increasing the resisting power of the soldier himself. It is true that the line has been equally unmindful of so potential an agent in securing efficiency in the soldier, devoting centuries to the development of the weapons of war, entirely regardless of the development of the men who were to handle them. Latterly, however, a new interest has arisen in the subject, and at some military posts useful work has been done with insufficient appliances. The sentiment of those officers who have given physical training a fair trial is unanimous in favor of its vast utility. Medical officers, however, have given it but little attention, although they alone are qualified to fully understand its value or to supervise its conduct.

The culture of the body, to be correctly accomplished, demands not only sufficient anatomical and physiological knowledge to locate defective parts, but sufficient pathological perceptivity to appreciate the advantages or dangers to be incurred by training these parts That it is impossible for any but a medical man to comprehend the needs of the body in the matter of training, has been recognized by the better class of instructors in physical culture, from Ling, the founder of the Swedish system, down to the great teachers of the present day, who have almost invariably qualified as physicians, as an essential preliminary to the proper comprehension and application of physical culture.

While physical training may with propriety be called muscle-building, it should be understood that the culture of every other constituent of the organism progresses *pari passu* with that of the muscles, to which the chief attention is given. It requires the most accurate notions of the muscular structure to select the individual muscle to which a part owes its weakness or lack of symmetry. The anatomical and physiological knowledge necessary to individualize and educate distinct muscles in such a manner as to produce symmetry and correctness of contour, and the maximum of strength combined with the greatest facility in its employment, demands special medical training. Anyone can run a tape measure about an arm, but it requires not only the information acquired in the dissecting-room and the physiological laboratory, but the power of discrimination developed by careful and intelligent clinical observation, in order to discover what particular member of a group of muscles is responsible for the lack of power which it is desired to correct. Not only does it require the most correct appreciation of muscular function to understand the particular movement or combination of movements adapted to the development of a defective muscle, but, in order to secure the best results, there must be a familiarity with the secondary and remote effects upon the other portions of the system.

The perfect man is a figment of the imagination. No person is known to have existed who was an embodiment of perfect health. A physical examination of the most vigorous would reveal in each some lesion of actual disease, some predisposing weakness, or both. The object of physical training is to take cognizance of physical deficiencies and correct them by movements adapted to secure growth. Hard labor is far from being an equivalent of physical training. It is true that laboring men acquire great strength in certain groups of muscles, but this gain is overbalanced by losses in others. The ploughman has strength in his arms, back, and legs, but he loses in his respiratory muscles and the anterior thoracic muscles. The deformities of occupation, due to the excessive use of one portion of the body, to the neglect of others, have a recognized place in orthopedics.

The material obtained by taking the average man is excellently shown in Prince Hohenlohe's description of the men obtained in the recruitment of his own regiment. "The barracks were soon full of figures that would put to shame the most exaggerated cartoons of the comic papers. The awkward fellows, whose neglected carriage made them look like a set of botched-up images, tried hard, but in vain, to stand erect. Ill made and undeveloped, their uniforms would not fit them, and, if altered to fit their present figure, would need to be remade when they should have been remodelled by physical training. So, before teaching them a single movement of the military drill, or providing them with uniforms other than their canvas fatigue suits, they were drilled in gymnastic exercises leading progressively and gently from the easy to the more advanced, until finally they had a reasonable command of themselves."

This picture reminds one somewhat of the appearance of the "candidates" at West Point. These young men have quite generally been subjected, before coming to the Academy, to a physical examination by a competent medical man and by him pronounced physically sound. But they are almost to a man awkward, unsymmetrical, and unevenly developed, making an appearance, as they are marched to the mess hall, fully as absurd as the conscripts of Prince Hohenlohe. And they form a particularly instructive contrast with the "yearlings" who have enjoyed the advantages of a year's drill in physical training.

Methods of recruiting employed by the regular army in times of peace to a large extent prevent the admission into the military service of men with muscles clearly undeveloped or atrophied by distinctly marked disease. Still it is not infrequent in my observation that men are enlisted, particularly by the regimental recruiting service, with defects or deficiencies sufficiently pronounced to contribute to their life for the next two or three years an important bearing upon their future health. While actual deformity or disease is a bar to the admission of the recruit, the variation in structure is so great that but a small proportion of recruits is either symmetrical or developed.

In the National Guard, where, for evident reasons, the physical requirements need not be as severe as in the regular service, the field for physical training is still broader and the results obtainable still more striking. Voluntary service lends to the work of the guardsman an enthusiasm which is an important factor in the attainment of the best results.

Physical training may by divided into two categories:

1. Preparatory training, by which deficiencies are corrected and a proper equilibrium of the system secured.

2. Conservative training, by which a well balanced state of the system is maintained after having once been obtained.

The preparatory training, particularly, demands medical supervision. Here the methods of physical diagnosis come into play. Mensuration, inspection, and palpation are of particular importance. In many gymnasiums mensuration is the only diagnostic method employed, but it is evident that it is necessarily insufficient, since

one group of muscles may be so over-developed as to neutralize, in the measurement of a limb, the effect of the atrophy of another—the girth of a part may be up to the average, and yet a very definite defect may be readily detected by experienced inspection, and its character appreciated by careful palpation.

As a general rule, weight, height, and breadth may be said to be in direct proportion to the strength. But the exceptions to this rule are numerous and pronounced. Weight may be due to an excess of adipose tissue, tending to produce debility rather than strength. Height may be due to excessive length of legs or neck, both elements of weakness. Breadth may exist with flaccid muscles and fatty deposits, which are incompatible with great physical power. As already suggested, there is usually a lack of harmony in development between the various parts of the body, and in this disproportion may lie the source of marked physical deficiency. The well developed chest and arms are more than likely to be accompanied by spindling legs. The limbs of the left side are, in a large proportion of cases, smaller than those of the right—an asymmetry which extends to numerous other details.

The preliminary facts upon which to base the preparatory training are of ten varieties: 1, The weight; 2, the height from the floor of the knees, the pubic arch, the sternum, and the vertex of the head, the latter with the body standing and sitting; 3, the girth of the head, neck, chest, waist, hips, thighs, knees, calves, insteps, arms, forearms, and wrists; 4, the depth of the chest and abdomen; 5, the breadth of the head, neck, shoulders, waist, and hips; 6, the length of each side from shoulder to elbow, elbow to tip of middle finger, of the feet and of the body laid horizontally; 7, the stretch of the arms; 8, the capacity of the lungs; 9, the strength of the lungs, back, chest, arms, and forearms; and 10, the development of the body. The appliances necessary for obtaining these data are a steel tape-measure, a large pair of callipers, several spring dynamometers, a spirometer, a manometer, a pair of suspended rings, and a set of parallel bars.

We are fortunate in having at our disposal at the present day the data based upon a large number of observations already made, by the consolidation of which types of manhood have been obtained. Sargent's observations are perhaps the best known and the most extensive, but in the records of the scientific gymnasiums of the country a vast amount of information can be obtained, particularly pertaining to the dimensions of youth and early adult age.

These data are exactly what is required by the surgeon in the examination preliminary to the preparatory training, for recruits are—invariably in time of peace—young men. Accurate examination of the recruit, using the eye, the hand, and the accessory instruments already enumerated, will show his deviation from the normal type, from which the exercises necessary to assimilate him to the normal will be a natural deduction. Muscular development depends on frequency of muscular action. The man with undeveloped calves would be given foot and ankle exercises, and he with a slender forearm would engage in the wrist and finger movements. The flattened chest would be brought out not only by use of the accessory respiratory muscles, but all exercises would, by causing deep and frequent breathing, cultivate the respiratory apparatus. The muscles of the neck and face can each be brought up by individual and combined movements. In connection with the special exercises prescribed for the compensation of deficiencies, the recruit will naturally engage with his comrades in other movements which will at the same time keep up the general physical tone, until he shall have attained a sufficiently uniform development to permit his passing into the class of the soldier and engaging only in conservative training.

The time during which the recruit remains in the preparatory class is very variable, being dependent upon two factors: 1, The amount of deviation from the normal type, and 2, the readiness with which he responds to treatment. During this period he should be continually under medical supervision, but when he passes into the second class, the personal medical inspection need be far less minute, although it should never be entirely withdrawn as long as the training is continued.

The soldier now enters upon the conservative training, extending to the general field of gymnastics where the exercises are numerous and varied. Every movement of the manual of arms and every evolution in marching have an effect upon the muscular system. But it is an error to presume that these are sufficient for thoroughly maintaining bodily efficiency. Not only are they by themselves insufficient for the maintenance of symmetrical development, but they even tend to the accentuation of asymmetry. The very existence of the "setting up" drill is an evidence of this fact. But while the expanded "setting up" drill, as now practised, serves excellently to correct the vicious attitudes imposed by certain phases of military duty, it is not competent, unaided, to maintain a high physical tone. Even were the prescribed military drills efficient in maintaining a symmetrical physique, they would soon, by constant repetition, become merely mechanical in their execution, a fact which would detract vastly from their usefulness. Physical training, in order to retain the interests of its participants, should be the subject of unlimited variation. There are no movements like those of the manual of arms requiring incessant repetition to secure precision in execution. Infinite diversity, then, may be obtained by the employment of the almost boundless category of muscular action—running, leaping, climbing, swinging, turning, lifting, striking, and the like, in various attitudes and with various surroundings, without apparatus and with the great variety of apparatus contributed by modern inventive genius. Athletic sports are also a powerful factor in stimulating interest in physical training, and for that reason should be heartily encouraged. The spirit of competition thus introduced into the work is of very considerable advantage, although a tendency, apparent at the present time, to subordinate physical training entirely to a preparation for participation in sporting contests, is to be deprecated.

An objection urged against physical training in the army is that the men do not take interest in it. This would hardly be supposed to be a valid objection to any plan looking to the improvement of the service. And moreover, it is not a valid objection. If there is absence of interest anywhere it is due to some defect in the management of the training. To put up a horizontal bar and a dozen dumb bells, and magnificently remark to a garrison: "There is your gymnasium, use it," is discouraging enough to ruin any project. The untrained man does not know how to use gymnastic apparatus. He may have seen the "Queen of the Air" swinging in a trapeze, but he quickly finds that circus acts are not physical training, and he naturally loses interest in the subject. He would lose interest in just the same way in the choicest book of Arabic that might be put before him. He must be taught how to utilize his opportunities. It is like any game, it must be understood to be enjoyed. And here is where the work of the medical officer comes into play and the instructors in physical training find their functions.

But he will require no instruction to appreciate the benefit of the training. The muscular growth begins at once; the size of the body increases; the circumference of the limbs is greater; the chest is enlarged, and the weight is augmented. The influence upon the system of the enlargement of the chest alone cannot be computed; the greater expansion permitted to the lungs, the greater play allowed to the heart, the greater amount of oxygen introduced into the system, the greater excretion of effete matter from the blood, with their secondary effect upon every cell and organism in the body cannot be expressed. The increased girth of the extremities is not

the only indication of their added strength, for it does not take into account the firmness and contractile power gained even before the growth began. The quickened sympathy between the brain and the muscles cannot be shown by any test. The suppleness, the agility, the self-confidence that have developed, cannot be represented by figures. The added keenness of perception, the comfort and satisfaction contributed to existence itself cannot be estimated, much less represented.

Physical training, then, should occupy a twofold place in the military service:

1. In its preparatory phase, it should be at the basis of all service (a) to build up to symmetry men whose physique is below the standard; (b) to improve the muscular harmony of all recruits, none of whom are symmetrical at enlistment; (c) to give to the men that ready command over the muscular system that only comes from thorough training; and (d) to contribute that quickness of mental comprehension only to be derived from exercising in response to frequently varied commands.

2. In its conservative phase, it should still remain at the foundation of all service. It is not enough to bring a soldier up to the maximum of physical serviceability, but he must be kept there. To overcome the retrograde tendency characteristic of all forms of life when stimulated to a higher grade, and no less present in physical development, a certain degree of training must be maintained constantly.

3. In both phases it should receive (a) the active personal support of the medical officer, for by strengthening the weaker portions of the system it will increase the resistance to disease and vastly diminish the sick-rate of his command; and (b) his most careful supervision as well, in order to insure the proper direction of the training and prevent excess in its application, an error in either case being sufficient to preclude a healthful growth.

The results of the scientific application of physical training to the military service will be wide-reaching in their beneficial effect.

1. The serviceability of the recruit will be more quickly obtained, not only by insuring the symmetrical growth of his frame, but by the awakening of his muscular activity and the consequent quickening of his mental faculties.

2. The efficiency of the entire army will be increased by the development of the physique of the units composing it.

3. The morality of the army will be elevated by substituting the healthful sports connected with physical culture for the less reputable amusements in which soldiers are sometimes tempted to indulge.

4. The economical administration of the government will be materially assisted, for training the soldier to physical vigor will result in keeping from the pension rolls the names of many who would otherwise promptly degenerate into helpless dependents upon the bounty of the State.

5. Not only will it vastly increase the efficiency of the military service, but it will have an extensive influence upon the entire community. As the years roll by, it will present to the commonwealth, upon their discharge from the army, a class of men, by their physical development and mental capacity, qualified to be more than ordinarily useful citizens. By its extension to the military schools, springing up all over the country, it will encourage healthful tendencies and manly inclinations in our youth. Through its adoption by the National Guard —always quick to adopt the best features of the regular service—it will disseminate physical development and intellectual activity throughout the young men of the nation. In every class of society, in every grade of life, wherever health is understood and length of life desired, its influence may be felt and its effects may be appreciated.

Edinburgh is Advancing, for there are now eight women practising medicine in that city and Leith.

ETHMOIDAL DISEASE.

By F. H. BOSWORTH, M.D.,

NEW YORK CITY.

Ethmoidal disease, both from the anatomical character of the region involved, and with reference to the symptoms to which it gives rise, differs essentially from diseased conditions found in any of the other accessory cavities of the nose. For whereas the maxillary, frontal, and sphenoidal sinuses present to us a single cavity confined by bony walls, the ethmoidal cells consist of a large quadrangular mass of small cells, or trabeculæ, varying in size, and each cell more or less completely separated from its neighbor by a thin, bony partition. This is fairly well shown in Fig. 1, the turbinated bone having

Fig. 1.—The Trabecular Character of the Ethmoid Cells, shown after the Removal of the Middle Turbinated Bone. From a Specimen in the writer's collection.

been removed. Hence while the problem which presents itself to us in dealing with morbid conditions in the other cavities consists simply in making an opening for proper drainage and irrigation, in dealing with diseased processes in the ethmoidal cells the radical arrest or cure of the disease, especially where suppuration has taken place, demands the opening of each of the large number of small cells which compose this mass. This is impossible. Hence we are compelled to resort to the breaking down of these small partitions within the ethmoid body in such a way as to convert it into one single cavity. And here, perhaps, it may be proper to say, that in a diseased condition of any of the accessory cavities I think we will all recognize the fact that the tendency in every case of a simple inflammatory process which does not undergo resolution, and which develops into a chronic inflammation, is to result in suppurative action, and thus the establishment of a more or less permanent pus discharge through the normal opening, namely, into the nasal cavity. The other respect in which disease of the ethmoidal cells differs from that of the larger sinuses is in that whereas in the latter we have simply a purulent discharge, in the former diseased action sets up a train of symptoms more or less neurotic in character, such as watery discharge from the nose, violent sneezing attacks, asthma, headache, neuralgias, which according to Berger and Tyeman[1] are usually intermittent in character; certain disturbances in the muscular control of the eyeball, asthenopia, and especially what has been called aprosexia. This latter really constitutes one of the most distressing symptoms of the disease, and has been described to me by patients as a sort of blanket over their brain which interfered with mental activity and the free use of their faculties. It is what the Germans call *Retentions-Erschöpfung*, and is defined in Billings's Dictionary as "inability to fix the mind upon a subject or to retain a lesson, accompanied by headache, and due to over-study or prolonged irritation in throat or nasal passages."

The topic which I am asked to discuss to day, as I understand it, is the surgical treatment of ethmoidal disease. Practically I suppose when we speak of ethmoidal disease we refer to suppuration in these cavities. The subject of ethmoid disease is to me exceedingly interesting, and is, I think, perhaps, the most interesting which is

[1] Dis. Ethmoidal and Sphenoidal Sinuses. Wiesbaden, 1886. (Compare also Schech.)

engaging the attention of laryngologists. I hope, therefore, that I may be allowed to refer somewhat briefly to the whole question of diseased processes here, prefacing this by the statement that I regard ethmoidal disease as not only by far the most frequent of all diseases of the accessory cavities, but as of very much more frequent occurrence than we ordinarily have been taught to believe, as will be inferred by the statement that in the past five years ninety-eight such cases have come under observation in my private practice. In the chapter on acute rhinitis, in all of our text-books on throat diseases, Bosworth among others, there is described a disease characterized often by nasal stenosis, frontal headache, intra-orbital pressure, asthenopia, watery discharge, and violent sneezing, which I very frankly confess I have rarely seen where I was enabled to detect a rational explanation of the symptoms in the morbid condition of the nasal mucous membrane alone, as seen by ocular inspection. I contented myself with the old teaching that these symptoms were to an extent reflex in character. I do not hesitate to say that I believe a very large proportion of the cases of so called acute rhinitis are really instances of acute ethmoiditis, and that such inflammation as may exist in the nasal mucous membrane is really secondary to the graver and more distressing conditions of the lining membrane of the ethmoidal cells. I thus endorse the statement made by that excellent observer, Moritz Schmidt, of Frankfort,[1] who, however, assigns these symptoms of a head cold to an involvement of some of the accessory sinuses, not confining it to the ethmoid cells.

Among the cases which I shall briefly analyze later, are a number of instances, both of acute ethmoiditis and suppurative disease, which have had their onset in unmistakable attacks of la grippe, which leads me to hazard the suggestion as to whether the influenzal type of la grippe is not really an invasion of the ethmoid cells by the specific bacillus which is supposed to be the exciting cause of that disease.

In a paper on ethmoid disease,[2] published two and a half years ago, I described five varieties of diseased conditions of these cells which practically reduced themselves to three, viz.: 1. Extra-cellular myxomatous degeneration; 2, intra-cellular myxomatous degeneration; and 3d, purulent ethmoiditis. I really think that, practically, we have but one primary morbid condition in the ethmoid cells, which progressively and with more or less rapidity develops into these three. In other words, that these three conditions are successive stages of one and the same disease. An acute inflammatory process of the mucous membrane lining these cells very soon either results in resolution or a chronic morbid process. Owing to the peculiar anatomical character of this membrane, a chronic inflammation tends to develop a soft, jelly-like thickening of the tissue, which takes on what we may describe as a myxomatous character. Now, this may persist for a somewhat prolonged period of time, giving rise to distention of the cells, with its train of symptoms already alluded to, which are, watery or muco purulent discharges, violent attacks of sneezing, headache, intra-orbital pressure, aprosexia, etc., and if the constitutional habit be neurotic, hay fever, and asthma, these symptoms being simply exaggerated on the occurrence of more or less frequently repeated attacks of acute inflammation, to which the patient is liable.

The further course of this disease I take it to be, in a certain small percentage of cases, is the crowding out from the ethmoid cells, through the normal opening, of this myxomatous tissue, which presents in the nasal cavity in the form of small polypi. Not that I believe the large proportion of cases of nasal polypi have their origin in the ethmoidal cells, for Zuckerkandl[3] has demonstrated conclusively that this is not the case. As the result of this inflammatory process within the cells, the thin walls become distended and we have a somewhat curious development, by which the outer wall of the cells yields before the pressure, and we have the middle turbinated bone crowded outward, and gradually an extension of these cells into this body. See Figs. 2 and 3. And here for the first time there presents a condition by which we may recognize a morbid process in the ethmoid cells

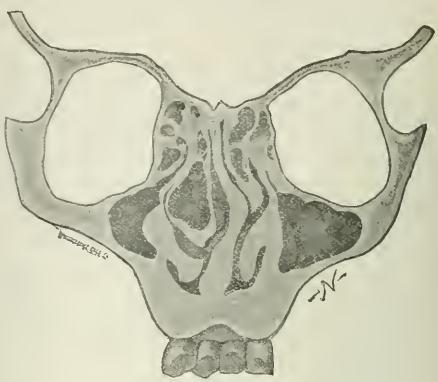

Fig. 2.—Distention of the Ethmoid Cells, with Extension into the Middle Turbinated Body. (Zuckerkandl.)

by ocular inspection through the nose; in other words, as far as rhinoscopic examination goes, in the inflammatory stage of the disease, this distention of the cells and extension into the middle turbinated body gives rise to a protuberance into the middle meatus, which is easily recognized, the middle turbinated body presenting as a rounded ovoid mass, usually in contact with the septum and encroaching notably upon the middle meatus of the nose. At the same time this curious myxomatous degeneration of the mucous membrane and lining cells conveys itself to the mucous membrane covering the outer wall, which is now the middle turbinated body in the nose, and lends additional aid in the recognition of the condition.

These two conditions constitute what Zuckerkandl has termed "ethmoiditis superficialis" and "ethmoiditis profunda;" the former term applying to the disease

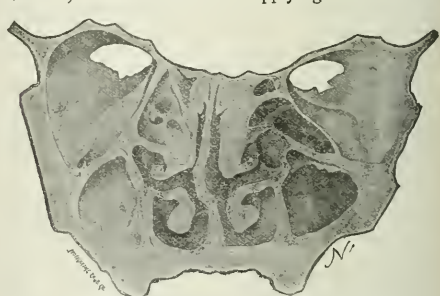

Fig. 3.—Distention and Extension of the Ethmoid Cells, with Displacement of the Middle Turbinated Body. (Zuckerkandl.)

when it is confined within the cells, and the latter designating the disease when the myxomatous degeneration has extended to the nasal cavity, making its appearance on the surface of the middle turbinated body.

The next stage in the development of the disease consists in suppuration. The time of its development may be very early or very late in the history of the disease, this being governed somewhat by adventitious circumstances. The method of its development seems very clear. The inflammatory process, involving the membrane within the cells necessarily gives rise to hypersecretion, which materially contributes to the intra-cellular

[1] Krankheiten der Oberen Luftwege. Berlin, 1894.
[2] New York Medical Journal, November 7, 1891.
[3] Norm. und Path. Anat. der Nasenhöle, Band 1, Auflage 2, s. 360.

distention, and also results in a closure of the normal orifice. The necessary consequence is practically the formation of an acute abscess, which, failing resolution, soon develops into a chronic abscess, or chronic suppuration of the cells, for I believe it to be an almost universal rule that where we have a chronic inflammation of a mucous membrane, with hypersecretion in a closed cavity, the tendency of the process is very rapidly to develop into a purulent action. We thus have established a chronic suppurative disease. The pus finds its exit through either the anterior or posterior ethmoidal cells; and I may state here, from a practical point of view, that the anatomical division of these cells into the anterior and posterior group is of no special interest to us in dealing with the diseased conditions, in that I believe they are really converted into a single group of cells by either a normal or a rapidly established abnormal opening between the two. The pus makes its way into the nasal chambers through one of the normal openings, either in front into the hiatus semilunaris, or through the posterior opening into the superior meatus. Thus on ocular inspection we may find the pus making its appearance either from beneath the middle turbinated body or from between the middle turbinated body and the septum above. As a rule, the pus from the anterior and lower opening makes its way into the lower meatus and is expelled through the anterior nares; while the discharge from the posterior opening makes its way into the pharynx, giving rise to the symptom so often complained of, viz.: that of dropping in the throat, in which way the disease may be confused with an ordinary naso-pharyngeal catarrh; although I should say here that the secretion of this latter disease is usually thick and adherent, and expelled by somewhat violent nasal screatus, whereas a dropping in the throat should always suggest the great probability of an empyema of either the ethmoidal cells or the sphenoidal sinus.

While the most natural exit for the pus is into the nasal cavity, this is by no means its invariable course, as is shown by the large number of cases in which the pus escapes through the os planum into the orbital cavity, giving rise to exophthalmus and orbital disease. Furthermore, we occasionally meet with exophthalmus from distention of the cells in the cavity, without escape of pus, as is still further and notably illustrated by the case reported by Bull,[1] of ethmoidal suppuration in which an artificial puncture through the orbit was followed later by a spontaneous rupture into the nasal cavities, the ultimate cure resulting probably from the latter.

As the result of the persistent suppuration the lining membrane of these cells necessarily becomes soft and very much thinned. The much-discussed question of necrosis of bone never has interested me greatly, because I regard its importance as much over-estimated. Zuckerkandl[2] states that he has never seen caries of the ethmoid cells, thus contravening Woakes,[3] who describes what he calls a necrosing ethmoiditis as practically the sole cause of nasal polypi. The membrane covering the bone is so far thinned and softened that to the impact of the probe it gives the sensation of being exposed. That it is genuinely necrosed I do not believe. The odor, moreover, which is almost constantly present in these cases in the later stage, is the odor of sulphuretted hydrogen developed from retained pus, and not the odor of bone necrosis. Hence in making our diagnosis I should not be disposed to attach so much importance to the use of the probe as many writers do, depending mainly for the diagnosis on the appearances about the middle turbinated body of distention, and on the myxomatous degeneration of the mucous membrane covering it. This deceptive sense of necrosed bone can be obtained by passing the probe either beneath the middle turbinated body toward the hiatus semilunaris, or above it toward the opening of the posterior ethmoidal cells in the superior meatus. I have frequently detected it in a normal and healthy nose.

Our most important consideration, of course, has to do with the question of treatment, and that this should be instituted early in the history of the disease and before the suppurative process has ensued need not be urged, in view of the very serious discomfort, and even danger, which attends the stage of empyema, and the great difficulty with which it is brought under control after pus formation has become chronic. In acute ethmoiditis the ordinary measures which our text books recommend in the treatment of acute rhinitis are indicated of course, and need not be dwelt upon, further than to say that of all measures I regard the use of the douche as most potent, directing that from one to two gallons of water rendered thoroughly saline be passed through the nasal cavities by means of the Thudichum douche at least twice daily. The water should be as hot as can be borne. This instrument I regard as devoid of the danger to the ears, of which Roosa has warned us, provided that the patency of each nostril be tested before its use and that the stream be made to pass into the narrowest nares, thus emerging without obstruction from the most patent side.

When the disease has reached the chronic stage without suppuration, I believe that, other measures failing, surgical interference should be resorted to in all cases, as we here have to deal with an affection which does not tend to undergo resolution, but one in which there is imminent danger of suppuration setting in at any time. The test that this chronic stage has been reached is to be found in the swollen and distended condition of the ethmoid cells, as shown by the projecting and swollen turbinated body, whether the mucous membrane covering it be in a state of myxomatous degeneration or simply turgescent. The object to be accomplished is to relieve intra cellular pressure, and this is accomplished by uncapping, as it were, the ethmoid cells. The steel-wire loop of the Jarvis or Bosworth snare is easily slipped over the projecting turbinated body and the whole mass removed, presenting usually in the form of an elongated ovoid shell. This also reveals to us the condition of the mucous membrane within the ethmoid cells, which may be either in a simple state of turgescence, or, as has not infrequently happened in my own experience, a soft, gelatinous mass of myxomatous tissue is found filling the cavity thus opened. If this does not drop out of place, it is very easily removed by the mouse-tooth forceps or the snare.

After pus-formation has occurred the problem before us, as before stated, consists in converting the large number of small cells which compose these bodies into a single cavity and establishing thorough drainage. In these cases the primary procedure is, as before, to uncap the cells by use of the snare, and after that I believe our best instrument consists in the use of the dental burr. Schaeffer, Moure, Cozzolino, Gleitsmann, and others prefer the use of the curette. I have never been able to freely manipulate this instrument in the ethmoidal cells or to break down the trabecular walls by its use. Its manipulation is hampered, and its action, to my mind, seems inefficient and not radical enough in extent. Grünwald's sharp spoon is a more efficient instrument, but still hampered in its action. The same criticism applies to the forceps and sharp spoon, as advocated by Zarinko.

That this disease can be radically cured, or even modified or controlled to any great extent, by the use of disinfecting lotions, as recommended by Lichwitz,[1] Hartman[2] Michel,[3] Schalle,[4] Myles[5] and Moure,[6] I do not believe. The small oval or round burr, attached to the dental

engine, or, better still, the De Vilbiss engine, in my hands has answered a better purpose than any other device. Manipulated with the De Vilbiss engine it is made to enter the ethmoidal cells either before or after they have been uncapped, when the trabecular walls are easily broken down or burred away. Its motion can be instantly arrested at will, when it can be made to act as a probe, exploring the cavity for exposed bone or such parts as it is desired to remove. In this manner our operation becomes not only intelligent, but, I think, absolutely safe, a consideration which of course is to be very carefully borne in mind, when we remember that we are separated in our operation not only from the orbit of the eye by an exceedingly thin plane of bone, but if we progress very far we are getting in close proximity to the base of the brain. I do not mean to intimate that at a single session the whole of the trabeculæ which constitute the ethmoidal cells can be opened out and thoroughly drained. In many of my cases the operations have been repeated a number of times at intervals varying from one week to a month, or even longer. During the intervals of course the patient is directed to use disinfecting lotions with as much intelligence and thoroughness as can be accomplished by the ordinary devices which we place in the hands of our patients for use. I have no special suggestion to make as to the character of these lotions, as thoroughness of application is of more value than the special character of the antiseptic used. Moreover, it should be stated that the operation is not attended with anything like the pain that we should suppose when we consider the exceedingly sensitive character of the parts operated upon. Of course the procedure is not an agreeable one, but it is not an especially painful one, provided that we can sufficiently reach the parts to thoroughly saturate them with a cocaine solution.

I may seem to the general practitioner to be discussing and describing not only radical but perhaps rough and even dangerous methods; but when we consider the great discomfort and distress to which a patient suffering from ethmoidal disease is subjected, and the still greater danger which threatens him, as has occurred, of involvement of other sinuses or neighboring cavities, such as the orbit, or even the development of the disease in the brain tissue itself, I think there can be no question that these radical procedures are not only fully warrantable but absolutely indicated.

The charge has not been infrequently made in the past few years that intra-nasal surgery has been very greatly overdone. Some of our English friends have delicately suggested that we attack the nasal tissues "with the energy of the backwoodsman," "with more energy than discretion," with recklessness and without justification. These charges are not deserved, and are unjust. We do not confine our work to the saw and burr and drill. The very large majority of our cases are dealt with without resort to surgical measures. But we meet with a large number of cases in which other measures are inadequate, and these we attack, not with the energy of the backwoodsman, but with the trained and delicate hand of the surgeon, who recognizes unmistakable indications and carries them out; the gratifying result fully justifying the means.

As before stated, during the past five years I have recorded in my private practice 97 of these cases, a brief summary of which I append. Of the 97 cases 3 were carcinoma and 4 sarcoma of the ethmoidal cells, which may be left out of consideration. As regards age, 3 occurred in the second decade of life, 14 in the third, 23 in the fourth, 28 in the fifth, 18 in the sixth, and 7 in the seventh decade. Sixty-one were males and thirty two were females. Fifteen cases were inflammatory in character, without suppuration or polypoid degeneration. Of these, 9 were cured, 3 were improved, and 3 disappeared. Twenty-nine cases showed myxomatous degeneration without suppuration. Of these 12 were cured, 10 improved, and 7 were seen but once or twice, and their progress not known. Twenty-two cases showed myxomatous degeneration, or fully developed polypi, together with pus discharge. Of these, 9 were cured, 10 improved, and 3 disappeared. Of the purely suppurative cases there were 27; of which 8 were cured, 12 improved, both as regards subjective symptoms and the amount of discharge, while 7 were seen but once or twice and not further noted. In nearly all these cases radical operative measures were instituted, as carrying out the suggestions already made. In many of them the simple irrigating measures failed to give relief, either to subjective or objective symptoms, and the cells were opened either by the snare or drill, or, and in many cases, both were used.

26 West Forty-sixth Street.

ON DYSPEPSIA NERVOSA AND GASTRO-INTESTINAL NEURASTHENIA.

By LEONARD WEBER, M.D.,

NEW YORK.

It is just ten years since Leube published his paper on "Dyspepsia Nervosa," and defined it as a disorder all the symptoms of which are caused by a functional disturbance of the nervous system, and especially of the nerves of the stomach, while gastric digestion remained normal both as to time and chemical process. Leube found this class of patients to be generally delicate, thin at the outset or in the progress of the complaint, rarely stout or of healthy appearance. In some cases there was a previous history of anæmia. Intermittens, renal or uterine trouble, sexual excess, or some real disease of the stomach that was cured, but left a state of nervous dyspepsia behind it; all cases were characterized by more or less suffering accompanying the act of digestion, which seemed to originate in the nervous system.

Prominent among the symptoms, as I have observed them, are a feeling of fulness and congestion in the head, headache, vertigo, cardiac palpitation, slight pseudo angina, dyspnoic oppression, abdominal pulsation. And on the part of the stomach a sense of pressure and fulness in the epigastrium, while palpation of the stomach generally reveals neither tenderness nor pain. Globus-sensation and pyrosis are rather frequent, and voluminous eructations of gas without odor or taste are very generally complained of. Nausea with occasional vomiting is not rare, and the vomiting may sometimes be rather severe and obstinate.

The appetite may be good, or bad, or changeable, and sometimes ceases after the patient has swallowed a few morsels. The bowels are generally constipated, seldom loose, almost always flatulent. In some cases nearly all these symptoms are present, in others again a few of them only. Great as Leube's merits have been in bringing the important subject of gastric neuroses prominently before us, it is nevertheless shown, not only by the labors of Ewald, Boas, Rosenthal, Bouveret, and others in this special field, but by the clinical observations of most of us, I believe, that Leube's standpoint is not sufficiently comprehensive, and we have to widen his definition of nervous dyspepsia, because we know that we meet numerous cases with all the symptoms of nervous dyspepsia, but also with disturbances of the secretory and motory functions of the stomach. Cases enough have been described where the secretion of hydrochloric acid is considerably diminished, insufficient for healthy digestion or even temporarily absent, not only for days but weeks; then normal again or increased, hyperhydrochlorie. There is generally a combination with motory weakness where hydrochloric production is diminished or absent, but with abnormal motory activity where there is supernormal secretion of hydrochloric acid. Gastralgia severe enough to simulate gastric ulcer with Burkhard's points douloureux in the region of the eleventh and twelfth vertebræ and in the epigastrium, I have noted sometimes, but they are variable and fugitive, not permanent as in gastric ulcer, aside of the other pathognomonic symptoms of the latter. From my own observations, therefore, I believe that for a

number of cases, at least, the designation "nervous dyspepsia" is too narrow, that they cannot be considered and treated apart from the other neurasthenic symptoms which are correlated to and associated with it, and that it is gastro intestinal neurasthenia as a part. Neurasthenia rather than nervous dyspepsia we have to deal with in a large number of cases. From my case-book I could add quite a little number of neurasthenias such as described by Ewald, and Burkhard, and Bouveret, who presented well-marked dyspeptic symptoms with the chemism of the gastric organ altered in various ways as marked above. It will be appropriate therefore, I think, to divide the cases into two classes: 1, dyspepsia nervosa with functional disorder of stomach; 2, neurasthenia gastro-intestinalis in general neurasthenia.

The causes of nervous dyspepsia are many. Aside of those caused by direct or indirect disturbance of the pneumogastric centre through cerebro-spinal disease or disease of peripheral nerves, there are gastralgias by reflex through affections of the genital organs, gall stones, renal calculus, a floating kidney, and the presence of intestinal parasites, particularly tape worm. But we are now concerned with those forms which are part of general naurasthenia brought about by physical or mental overexertion, or both, excessive care and excitement, sexual excess, debauch, masturbation, or by intoxication such as malaria, morphine, nicotine; also those by hysteria and such constitutional anomalies as chlorosis and anæmia.

With regard to age, sex, and the influence of life's vocation, my experience coincides with that of all other observers, I believe: *i.e.*, gastro-intestinal neurasthenia is prevalent among men between twenty and thirty, and is more often seen among brain-workers than among mechanics, though I have quite a little experience with the latter class also in that direction. Women are perhaps less often affected than men, and, for reasons easily understood, at an earlier period of life. With regard to children I have no personal experience of value, but some observers maintain that the disorder is not as rare among them as is generally supposed.

Now, with regard to the treatment of dyspepsia nervosa, I have always been delighted when I got hold of a case where I could remove or control the cause, and feel sure then to cure, or almost cure, my patient. For instance, a tape-worm by giving 10.0 of extr. fil. mar., a displaced uterus by a pessary, a floating kidney by a suitable truss, an irritable urethra by the use of the steel-sound and tepid sitzbath. Or when anæmia or chlorosis was at fault, by iron, quinine, and arsenic, salt-water baths, and change of climate, and by the elimination of malaria and nicotin poison where the attacks were produced by them. Of nerve drugs, I am not in the habit of prescribing opium or cocaine, except where there is severe gastralgia present; here I often use a cold wet bandage over the abdomen with a coil on top of it through which hot water is allowed to flow for some time—a plan of application suggested and recommended by Winternitz, that will often bring relief without morphine. Extractum cannabis, however, introduced by Germain-Sée in the treatment of nervous dyspepsia where there is much sense of pressure and discomfort felt after eating, I have often prescribed in doses of one sixth of a grain t.i.d, and been well satisfied with the results obtained. Some praise here the use of aqua chloroformi or atropia. Electricity also does well here, with a very large electrode over the epigastrium, as first proposed by von Ziemssen, especially also where there is a good deal of motory weakness of stomach. In cases accompanied by obstinate vomiting, I have found nothing answer so well as to make the patient fast for two or three days, giving meanwhile nutritive enemata. Last, but not least, a Weir Mitchell rest and feeding cure will be of service in certain female cases too well known to need description, and in those of men who are much reduced and present hysterical symptoms.

I wish that I could say half as much of positive results obtained by me in the management of cases of gastro-intestinal neurasthenia in neurasthenics, leaving out of consideration altogether those caused by organic disease of the central nervous system. So long as I did not understand the causal connection, or rather inseparable relation and interdependence of the general and local condition, I tried for cure and failed in the one as well as in the other state. Now that I know we cannot yet cure a case of grave neurasthenia, although they have quite occasionally a queer way of getting better by themselves, I do not try any more to cure them by active treatment, but I do them more good than before. By dealing more with the individual, regulating his life, correcting his had habits, admonishing him to spare himself and pay close attention to his dietary, physic his bowels from time to time to remove putrid material, and go on short vacations two or three times a year, I believe to succeed pretty well in keeping them in fair order not only, but putting them actually in the way to get as nearly well as they can. Of symptomatic remedies I know none better than those mentioned in the first class of cases, which we may more truly call nervous dyspepsia than the latter.

To be sure, we all know of neurasthenic dyspeptics who went to the high Alps of Switzerland, or to fine places at the sea, or to specially fitted sanatoria here and abroad, and were sent home cured. No wonder that they came home better after doing the very best things for themselves under the best possible conditions of climate, food, care, and rest, and recreation of mind and body; but it is at best a great improvement only, and it is generally not very long before we see them return to us with their old complaints.

25 West Forty-sixth Street.

Progress of Medical Science.

The Absorption of Iron. — Dr. Macallum finds that inorganic iron is absorbed (in guinea-pigs) by the intestinal mucous membrane. Whatever iron salt was administered, whether the phosphate, chloride, sulphate, or "peptonate," when the dose was not very large, the evidence of its absorption was very plain in the villi of the upper end of the small intestine, but in them only (*The British Medical Journal*). When the dose was large, the presence of iron in the villi was observed far down the intestine, but the reaction for iron was less distinct the more remote the villus from the pylorus. With very large doses of the phosphate or "peptonate" the villi near the cæcum gave an intense reaction. It is suggested that the reason for this difference is that when the dose of iron is small, and when, consequently, the quantity of iron in the chyme is small, it is wholly precipitated by the alkaline, biliary, and pancreatic secretions; as these three fluids do not at once and completely mingle, the iron is not at once precipitated, and consequently absorption goes on in the first few inches of the intestine. The acidity of a larger dose of iron salt may be sufficiently great to destroy the alkalinity of the chyme after admixture with the bile and pancreatic juice, and, when this is the case, the unprecipitated excess of iron-salt will go on down the intestine, and be absorbed lower down. When the oxide or the reduced metal is given, a certain quantity of the acid of the chyme is taken up in effecting their solution, and therefore in the intestine the alkalinity of the bile and pancreatic juice must go farther in the precipitation of the iron. Speaking generally, the larger the amount of free acid in the chyme the greater must be the quantity of iron absorbed. Sulphides in the contents of the bowel will also precipitate the iron still in solution. On an ordinary diet, therefore, the extent of intestinal mucous membrane which absorbs iron must be, in proportion to that which does not, remarkably small. Macallum, however, thinks it possible that in anæmia there may be a diminution in the amount of the biliary and pancreatic secretions, a condition which, for the reason above stated, would prevent precipitation, and thus favor

absorption. His grounds for stating that iron salts are absorbed, a fact which has been denied, are drawn from microscopical examination of the mucous membrane under various conditions. In well-fed guinea pigs taking iron, the intestinal mucous membrane, after treatment with alcohol, assumes, when treated with ammonium sulphide, a more or less dark color, due to the formation of sulphide of iron, which, under the microscope, is seen to be limited to the subepithelial portions of the tips of the villi. Here it is deposited in leucocytes which surround the end of the lacteal vessel. When the dose of iron is larger, or, apparently, when the administration is continued for a long time, the iron is present also in the epithelial cells themselves, and passes from them by a process of internal secretion into the plasma of the venules. These venules are the portal radicles, and leucocytes containing iron are found in capillaries of the liver, and the peripheral cells of the lobules contain iron. Similar leucocytes are found in the spleen. Beyond this point the iron was not traced, and the question whether it is ultimately assimilated and fixed as inorganic iron remains unsettled; but the research serves to prove that iron salts have not, as has been asserted, merely a stimulant action on the epithelial cells of the mucous membrane. Any stimulant action they may exert is a concomitant of their absorption. Though some of the subepithelial leucocytes of the villi appear thus to carry part of the absorbed iron into the general circulation, the more important agent in the transferrence of the inorganic iron from the villi to other parts of the body is the blood plasma.

Thioform —Dr. Julius Schmidt states that thioform is a grayish yellow powder, which is a chemical combination of bismuth, sulphur, and salicylic acid. It is tasteless and odorless, insoluble, and was first prepared as a substitute for iodoform. This expectation has been verified in so far that surgically its value is equally great, but the specific action of iodine as required in tuberculous affections is not obtained. When applied to fresh wounds thioform produces rapid drying of the surface, leading to a more rapid cicatrization than has been observed after the use of any other application; this was noticed even in extensive surface lesions, such as burns, weeping eczema, and gangrenous patches, the latter having healed in four days. The author tested the powder in five cases of ulcer of the leg which had resisted other treatment. The ulcer having been cleaned and disinfected, the thioform was thickly dusted over it, and covered with cotton-wool and a bandage. Every fourth day the whole dressing was changed, and though the patient continued to walk during the treatment, the cure required two or three weeks only. Some pain was occasionally produced, but no sign of irritation could be seen. Similar results in the practice of other surgeons are given. Finally, the author used thioform internally after having satisfied himself as to its non-poisonous character, and with daily long-continued doses of fifteen grains, better, though similar, results were obtained than with salicylate of bismuth.

Tuberculous Typhlitis and Appendicitis.—Dr. Reclus observes that the clinical reports of tuberculosis of the cæcum have accumulated rapidly during recent years. The cases of Boully, Terrier, Hartmann, Reynier, Broca, Roux, Salzer, Billroth, and Hochenegg, the anatomical researches of Duguet, Spillmann, Hérard, Cornil, and Hanot, and the recent descriptions of Pilliet and of Le Bayon, have thrown some light upon this hitherto but little recognized affection. The cases have been numerous enough for one to attempt to tabulate a statement of the clinical manifestations of tuberculous typhlitis and appendicitis. Reclus himself has observed two cases where a long-continued clinical history has been sustained by post mortem examinations. This affection may manifest itself as a localized tuberculosis without infiltration, without concomitant degeneration of the lungs and other important viscera, developing itself around the ileo cæcal valve and its vicinity without invading the other tissues. This suffices to class this tuberculosis among the surgical tuberculoses; from the moment it is confined to a limited focus and this focus is accessible, in such favorable circumstances intervention is legitimate. Therefore, in certain cases—and the observations are becoming daily more numerous—perityphlitic tuberculosis is an ordinary surgical affection. As to the etiology of this condition the literature is scant; the degeneration here, as in most of the other tuberculoses, seems most frequent in adult age, but the young do not escape; a little boy aged ten has been cited as dying from this affection; the greatest number of the cases published, however, have been in individuals who neighbored upon or who had passed thirty years of age. It seems that two distinct anatomo-pathologic forms may be described, associated with different symptoms: the one a fibrous or hypertrophic and the other an ulcerous variety; moreover these may be combined, or there may be noticed all the intermediate stages between them. The majority of the cases thus far reported have been characterized by an abundant new-formation which gave to the degeneration the appearance of cancer. In this form, the tumor after incision of the abdominal parietes appears fused with the double parietal peritoneum, with new membranous formations which cover the intestines and mark their limit; the original form of the cæcum and its appendix, the ascending colon, the ileo-cæcal valve, and the termination of the ileum cannot be recognized. There is a muscular and a mucous hypertrophy at this point which causes the intestinal wall to measure at times up to three or four centimetres. The lesions ordinarily are most marked around the ileo-cæcal valve; the valve is profoundly altered from the beginning; in its place is found an irregular cavity, covered by a partly ulcerated mucosa; the loss of substance is irregular, its edges sinuous, the base sanguineous with small rigid villosities. The appendix is bent upon itself and adherent at times in front of the cæcum, at times behind it; it is lost in the thickness of the false membrane.

The second or ulcerated form may present thickening of the serous and false membranes around the intestinal loops, but these have not the remarkable hypertrophy of the other form; on the contrary, the ulcerative process predominates, the mucosa has often completely disappeared, especially at the site of the ileo-cæcal valve, where ordinarily a veritable cloaca is found due to the destruction and anastomosis of the various intestinal segments. The softening of the cheesy masses in the tunics and the neighboring ganglia has given rise to puriform collections, which run in various directions, but generally make their way toward the abdominal wall; through the resulting fistulæ fecal matter and pus escape. These pyostercorous canals are often multiple. There exists a third form which Professor Cornil has especially studied. Often, in place of the fecal concretion which forms in the appendix, some foreign body, bone, a fruit seed lodges there, and by its presence irritates or perforates the vermiform process and tuberculosis forms, the bacillary colony destroying the walls. The symptom of the first form in the beginning is the existence of deep pains in the region, lasting for some hours during the day, then disappearing and appearing anew. This attack subsides only to reappear in a few weeks in a more aggravated form. Constipation accompanies it and may be extreme. On examination the presence of a tumor is demonstrated in the right iliac fossa, hard, resisting, bosselated, irregular. In these cases where softening has taken place fluctuation may be pronounced, or the skin becomes red and the abscess opens with the formation of a fistula. The diagnosis becomes plainer still when in place of the extreme constipation a rebellious diarrhœa appears resulting from the abundant and persistent ulcerations of the mucosa. The general health does not suffer in either form at first. As to the treatment of these cases, surgical intervention is the only proper and justifiable course.—*The Medical and Surgical Reporter.*

Clinical Department.

A SOURCE OF INFECTION IN CORNEAL ABSCESS.

By J. H. THOMPSON, M.D.,

CLINICAL PROFESSOR OF OPHTHALMOLOGY, KANSAS CITY MEDICAL COLLEGE, KANSAS CITY, MO.

It is not the purpose of this paper to consider the nature and variety of micro-organisms which cause abscess of the cornea. The probabilities are that the septic cases are responsible for most purulent inflammations of that tissue. But it is important to learn where these septic germs arise and how they reach the eye. We know that the tears and conjunctival secretions contain them, and late investigations have proved that the cutaneous edges of the lids, especially about the roots of the lashes, are surgically unclean. The greatest source of infection is the lachrymal sac, and woe be to an eye if its cornea is injured during the course of a purulent dacryocystitis. I am inclined to the opinion that the pyogenic cocci are not always so virulent as we have been taught to believe; for very few eyes could survive the simplest operation which necessitated an incision or puncture of the cornea. Therefore, it is not unreasonable to think that in a large majority of instances the conjunctiva of an unwashed eye is, for all surgical purposes, aseptic.

In an experience of fifteen years, during which time I have made many extractions and corneal incisions, I have never had an instance of suppuration, and I do not take any antiseptic precautions other than wiping the lids with a bichloride solution, 1 to 2,000, taking care that the instruments are clean. Of course, it is to be understood that all such cataract operations were made on uninflamed eyes.

Many cases of abscess of the cornea are the result of infection from the lachrymal sac, the mucosa of the sac being in a condition of purulent inflammation. Many other cases of corneal abscess are not complicated by that disease. In such instances I have usually found the source of the infection to be the mouth. It is not an exaggeration to say that the mouth of an unclean adult is often extremely dirty. Should the reader desire proof of this statement, let him examine the teeth of the ordinary dispensary patient, or, what is more agreeable, take the opinion of a dentist. Unless extra care is taken by most persons the tartar will collect around the roots of the teeth, which will ultimately excite an alveolar pyorrhœa and, finally, recession of the gums. During the course of that disease the mouth may be horrible and the smell disgusting. No wonder the bite of such persons can be fatal. If we take a minute particle of the mass of decomposing food and pus from between the rotting teeth and examine it through an eighth objective, after staining the cover-glass preparation by Gram's process, we will be astonished at the multitude and variety of micro-organisms. I cannot conceive how the pharynx and nasal passages can be healthy if the mouth is so diseased. The mass of organisms cannot remain localized about the teeth, but must infect the entire mucous tract, and by continuity reach the conjunctiva. They do not necessarily inflame that membrane, nor do they excite such disturbances in the lachrymal passages as would be detected by the patient or careless observer, but the mucous membrane of the eye is infected when an intentional or accidental wound of the cornea may suppurate.

For some time I had been suspicious that there was some relation between a dirty mouth and a suppurating cornea, when the following case rather convinced me.

M. B——, aged forty-three, a farmer. While cutting weeds something hit him in the eye. He did not pay any particular attention to it, and would have forgotten the accident had not his eye inflamed three days afterward. He was cared for by his family physician, who referred him to me ten days after the accident. When I saw him, his cornea was destroyed by an abscess. He had no disease of the lachrymal passages, but his mouth was fouler than the uninitiated can conceive. His breath overcame me. Is it surprising that he lost his eye?

Some weeks ago I saw another similar case.

F. N——, aged about thirty, laborer, was wounded in the left eye by a piece of stone. He complained of the injury from the first, and, when I saw him several days afterward, he had a suppurating ulcer of the cornea with hypopion. The ulcer was round, 3 mm. in diameter, with a dirty white floor and ragged edges. There was no evidence of dacryocystitis, but there were evidences of a foul mouth. The ulcer was completely destroyed by the actual cautery; the eye bathed every two hours with a bichloride solution, 1 to 4,000. The patient was introduced to, and taught the mysteries of a tooth-brush, as much care being taken to clean his mouth as his eye. The eye did not improve, and when the hypopion filled the anterior chamber, I made the Saemisch cut, and removed the pus *en masse* with forceps. From then on the patient improved, and was discharged six weeks afterward with useful vision.

At present I have on hand a case of hypopion keratitis evidently caused by infection from the mouth. The patient is an Italian miner, who has suffered for years from alveola pyorrhœa. His mouth is in a dreadful condition; the roots of all his front teeth are exposed, and the spaces between them and the receding gums filled with tartar, pus, and decomposing food.

If the source of infection in the cases above reported was the mouth, it behooves us to pay some attention to oral cleanliness in the treatment of suppurative keratitis; and since this may account for some distressing and unexpected results following cataract extraction, we should be especially careful in that regard before undertaking that operation, since we know that old people are apt to be careless, and usually suffer from bad gums and decayed teeth.

AN UNUSUAL CASE OF PERFORATING APPENDICITIS—DEATH FROM HEMORRHAGE DUE TO RUPTURE OF THE COMMON ILIAC VEIN.

By J. C. LEWIS, M.D.,

PANAMA, N. Y.

B. E——, fourteen years of age, was taken sick on Friday, March 23d, with vomiting, chills, and pain in the bowels. The pain increased in severity until Sunday, March 25th, when I was called to see her. I found the patient inclined to lie mostly on the right side, with limbs flexed. Temperature, 103° F.; pulse, 135. Her bowels were slightly swollen and tympanitic, with tenderness especially marked in the right iliac region. The patient had taken for her relief nine of "Carter's" pills and one tablespoonful of castor-oil, without, however, obtaining any movement of the bowels more than a few small scybalæ, and at one time, on Saturday, March 24th, about a tablespoonful of fresh blood was passed. The patient ascribed her sickness to some peanuts which she had eaten at a party on Friday evening, March 16th.

The treatment pursued was the use of large enemas with opiates to relieve the pain. On Monday and Tuesday the symptoms were unchanged, except that the temperature rose to 104° F., the pulse varied from 120 to 140, the countenance became cadaveric and expressive of severe pain. The swelling and tenderness in the right iliac region became more manifest, with point of severest pain an inch below McBurney's point. On Tuesday, while up in a chair, the patient fainted away, and it was quite difficult to restore her, and for an hour or more her breathing was labored. The enemas had been continued without any success. I became convinced that the patient had appendicitis and recommended an operation. On Wednesday, Dr. Murphy, of Sherman, N. Y., saw the case with me and confirmed the diagnosis, but advised waiting two days and keeping up the

use of the enemas, as her symptoms seemed somewhat improved, the pulse having come down to 100, and the temperature to 100½° F., and the countenance was improved, though pain, swelling, and tenderness of bowels remained the same.

On Friday, March 30th, with a view to an operation, Dr. Seabury, of Sugar Grove, Pa., was called, and met Drs. Murphy and Glidden. The patient's condition was unchanged, except that the pulse was down to 90, and the temperature for the last two days had ranged from normal to 100° F. The result of the consultation was a delay in the operation. On Saturday, A.M., the temperature was only 96½° F., and the condition otherwise unchanged, except that the swelling in the right iliac region seemed less prominent. The bowels were but little swollen and tympanitic, but pain was not lessened. The bowels had not moved from enemas, which had been continued.

Dr. John Parmenter, of Buffalo, was called, and operated in the presence of Drs. Seabury, Glidden, Murphy, and the writer.

At the time of operation the physical examination showed a good countenance, a clean and moist tongue; respiration, 20; pulse, 100 (full and regular); temperature normal; abdomen slightly tympanitic and not remarkably tender. In place of a perceptible tumor, only dulness was manifest in the right iliac region. This extended toward the median line. Cœliotomy was made in the median line, and after cutting through the abdominal wall pus welled up in the incision. Omentum formed the background and seemed intimately adherent to the intestines beneath. The pus seemed to come mostly from the right side, and upon examination a large abscess cavity was discovered in the right iliac region. Incision was made over this; that is, at the right border of the right rectus muscle, through which a pint and a half of malodorous pus was removed. The intestines were found matted together, and for fear of disturbing the adhesions no force was used in the abscess cavity. This was drained with iodoform gauze, a counter-opening in the loin having first been made in order to more freely drain the parts, and the patient was put to bed in practically the same condition as before the operation. She became restless in coming out from the anæsthesia and tossed about in the bed, requiring the efforts of the bystanders to restrain her. An hour after the operation she became restless a second time and showed signs of collapse. Examination revealed the bed and the dressings posteriorly to be saturated with blood, and, notwithstanding the generous use of stimulants, she shortly died.

Autopsy, immediately after death, revealed the following conditions: There was pus throughout the whole abdominal cavity, covering all the viscera, even occupying the space between the liver and diaphragm. In the right iliac region, the ileum for some twelve inches was intensely congested, and at the junction of the ileum and cæcum the parts were gangrenous. The cæcum contained three gangrenous openings, averaging one-fourth of an inch in diameter. The distal three-fourths of the appendix was gangrenous and separated from the proximal end, and lying in the *débris* was a peanut. The healthy condition of the proximal end precluded the idea of the peanut having passed through from the cæcum by this route, so that the inference is that it must have come through one of the openings in the cæcum and was deposited in the neighborhood of the appendix. The portion of the ileum near the junction at the cæcum, as before stated, was in a gangrenous condition and bent sharply downward to become attached to the common iliac vein. In this latter structure a small opening, out of which exuded blood, was discoverable, and from this area, through the posterior opening in the flank, blood had continually poured until death ensued. The amount of blood exuded in a given time must have been comparatively small, and in all probability the rupture of the vein occurred during some of the violent movements of the patient on coming out from her anæsthesia, for at the time of the operation no hemorrhage of any kind was perceptible.

The following features seem worthy of notice:

1. The absence of marked symptoms of diffuse suppurative peritonitis.

2. The cause of death—from hemorrhage.

3. The absence of fecal impaction, which was supposed to exist in connection with appendicitis, from the fact that no satisfactory movement of the bowels had been obtained after the taking of so much physic.

4. The necessity of an early operation in cases presenting marked symptoms of appendicitis.

THE INFECTIVITY OF PHTHISIS PULMONALIS —AN INSTANCE.

By CHARLES O. MAISCH, M.D.,

NEW YORK.

Some weeks ago I was consulted by a man whom I have known for a number of years, whose mode of living, surroundings, and family were perfectly well known to me.

The patient is a German, sixty-two years of age, well preserved, and weighs about two hundred pounds; antecedents and family history good, except that he had pneumonia a year ago.

He states that he has lost forty pounds in the last four months; his complaints are those of a patient in advanced consumption—cough, profuse expectoration, occasional hemorrhages, anorexia, sweating, wasting, etc.

Physical examination disclosed both apices to be involved, and the sputum I examined contained the tubercle bacillus in large numbers.

The further history is important. Two years ago this man lost a son, aged twenty-three, who, after a sickness lasting six or seven months, died of pulmonary tuberculosis. About three months later, the young man's mother, who had been nursing him, began to sicken. She was a German, fifty-nine years of age, strong, robust, and well-preserved, weighing upward of two hundred and twenty-two pounds, and had a good family history. She gradually failed, and died after an illness lasting some twenty months, during the last of which she had frequent hemorrhages from the lungs and intestines, and almost constant diarrhœa.

This was five months ago. Upon visiting my patient at his home, I found that he always expectorated on the walls, floors, and in the corners of his apartment, the place of special selection being under his bed. This had also been the practice of the deceased members of his family.

The daughter who takes care of the sick man says that their attention had never been drawn to any danger from this habit, but that the physician who had attended ordered a saucerful of black (crude) carbolic acid to be kept in the room, evidently with the intention of combating or lessening the evil.

It is, of course, impossible that the emanations from a saucerful of crude carbolic acid would have sufficient germicidal potency to make any impression upon an atmosphere loaded with the germs of latent tuberculosis.

There have been two deaths, a third member of the family is hopelessly sick, and a fourth, a daughter, aged twenty-two, is worn out and delicate from long and constant attention to the sick (brother, mother, and father). She sleeps in the same room with the sick man, and slept at the side of the mother during her illness, constantly inhaling the dried products of the expectoration, which were everywhere, and she now is in a fair way to become phthisical, if she is not so already.

Without entering upon the details of what prophylactic measures should have been employed in these instances, it will be readily seen that, with proper hygienic precautions and intelligent co-operation of the family in the first case, the last two, and possibly the third, would probably not have occurred.

90 Madison Street, September 9, 1894.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, October 13, 1894.

OLIVER WENDELL HOLMES.

How familiar has been the sound of this name! How deep is the regret with which we add in reverential tone that Doctor Holmes is dead. But is he dead? Do such men really die?

He has won the love, the admiration, the respect of two hemispheres; his influence has extended as far as the English language is understood; his teachings have been a benefit to the whole human race. His loss is not one to be felt by one community. Boston cannot claim him, nor Massachusetts, nor North America. He belongs to the world. Proud as we are to think of him as a member of our profession, and proud as we are of his achievements in it, we realize that his great work in life had more to do with making people better spiritually than making them well physically. Physician by education, he devoted himself to practice and the acquisition and imparting of scientific knowledge. Poet by nature, he spent his leisure time and declining years in those writings which have so endeared him wherever they have been read. Philosopher by thoughtful study and love of his fellow-man, he made for many life's path less rugged by kind and philanthropic words, and when his own long path brought him toward life's foot-hills he was content and said, "he should sorrow deeply if he had the idea he was to become helpless in body and mind." This was spared him. He reached the end, "eighty-five years young," as he has expressed it, and happily met death as a little child meets sleep, unconscious of fatigue, and only mindful of a day more full of pleasures than of pain.

To his students of twenty or thirty years ago, as they recall the words of the genial Professor in describing the arch of the female pelvis, "Gentlemen! this is the triumphal arch under which every candidate for immortality has to pass," the thought must occur how nearly has been attained that immortality of which he spoke, and how like a triumphal march the whole modest life!

Almost the last leaf upon the tree (for nearly all his contemporaries had fallen from the bough which bore the date of his birth and college graduation), he still clung to it with a vitality which indeed elicited a smile, but one wholly of admiration, and carrying with it a "God bless you!"

The ever-speaking presence in his charming books, the genial infusion therein of his cheerful spirit, the lofty tone of his pathos, the sound philosophy of his humanity, the soul-touching sweetness of his poetry, the subtle humor of his generous and loving nature, will keep him always with us through the never-ending flight of future days.

THE PERCENTAGE OF IRREGULAR PRACTITIONERS IN THE UNITED STATES.

ACCORDING to Polk's Register, Toledo, with a population of 100,000 in 1890, had 209 physicians in 1892, of whom 70.3 per cent. were regulars. In Cincinnati, a city with a population of 296,908, there are 596 physicians, of whom 70.6 per cent. are regulars. In Cleveland, with 270,000 inhabitants, there are 545 physicians, of whom sixty-three per cent. are regulars.

Out of the first hundred names (*Medico-Surgical Bulletin*) taken from a list of physicians in small towns, arranged alphabetically by post-offices, including Aberdeen, Ada, Adams Mills, etc., we find sixty-six per cent. classed as regulars.

The explanation of this lies in the number of cheap medical colleges. Ohio and Missouri are States which are offensively prominent in this respect. Thus Ohio has a population of 3,672,316 and seventeen medical colleges, while New York, with a population of 5,997,853, has only twelve.

The evil is being slowly corrected, however, and we have no doubt that in ten years the percentage of educated physicians will be greatly increased, while at the same time that of cheap medical colleges will correspondingly decline.

It would be quite unjust also to suppose that two-thirds of American physicians are irregular practitioners and uneducated men. In New York, for example, the law requires evidences of graduation from a college of respectable standing, and the percentage of ignorance is small. The same is true of many other States.

FOOT-BALL AS A MEANS OF PHYSICAL DEVELOPMENT.

THE advent of the foot-ball season has already given rise to discussions about the value and dangers of the game. As to the dangers there is no longer much dispute, and it is stated that the new rules will not make any appreciable difference. We can only trust that the record of last fall's mortality will not be repeated.

As to the practical advantages of the game as a means of physical culture and mental stimulus, there is still much controversy. What is wanted is, however, not so many opinions and more facts. Dr. Beyer, in the *American Journal of the Medical Sciences*, has contributed somewhat to our actual knowledge of the matter. He finds that in the Annapolis Academy the foot-ball players are four per cent. superior in height, twenty-eight per cent. in weight, twenty-one per cent. in lung capacity, and forty-nine per cent. in total strength. These were only average players, many of whom never played in a big game, and nearly all the measurements represented the player as he was at the beginning of the training period. Between the average Yale student and the average American foot-ball player, the players were one year and one month older, but they were 2.8 per cent. taller, twenty per cent. heavier, had ten per cent. more lung capacity, and were forty per cent.

stronger than the fifty mercantile grade of Yale students. Between average American players and Amherst students the comparison is on rather a different footing, because here the students are nearly two years older than the players; but the latter have a superiority of three per cent. in height, twenty-three per cent. in weight, twenty per cent. in lung capacity, and thirty-seven per cent. in total strength.

This all shows simply that the bigger, stronger, and more active men are selected for foot-ball. As it is just the opposite class who most need physical education, it seems as if these figures furnish a very telling argument against foot-ball as a means of securing a good general athletic training. The strong boys train and play; the weaker sit around, drink beer, smoke cigarettes, and shout.

Dr. Beyer gives some further statistics which have a rather academic interest. They show that after two months work at foot-ball, the player gains four or five per cent. in weight, about four per cent. in lung capacity, and fourteen to sixteen per cent. in general strength. This gain in strength continued for a long time after training. The lung capacity was not much increased. As compared with rowing and gymnasium work, Dr. Beyer shows that foot-ball is inferior as a means of physical development, as by the first two methods the physical strength was increased about twenty-eight per cent.

The case for foot-ball is not helped by Dr. Beyer's investigation.

AN ANTI-CORSET LEAGUE.

Every month brings us news of a new "anti-" society. We gave notice recently of the formation of an anti-opiate league; now the London papers inform us of an Anti-Corset League, which has been organized at Liverpool.

The objects of this association consist in inculcating true principles of clothing, which neither offend the eye nor the requirements of health. The use of the corset will be specially discouraged, but its place will be taken by an easy and natural form of support, consistent with the wholesome development of the body and the due exercise of its functions.

This easy and natural support is not to be the male arm, as might be supposed by frivolous minds, but is a pliable, plaited affair, conforming to hygienic principles and the natural curves of the trunk. There is no article of apparel which has been so vigorously, and we have no doubt justly, criticised as the corset; but it stays just the same, and we fear it will continue to do so. However, the Anti-Corset League has our sympathy and support. The corset is always a source of some danger, and in a good many cases does positive harm.

Placarding of Apartments Where Contagious Disease Exists.—At the last meeting of the Board of Health a recommendation made by Dr. H. M. Biggs was adopted, providing for the better protection of the public by the placarding of all apartments where there are contagious diseases. The warning placards are to be in different colors: white for diphtheria, red for scarlet fever, and blue for measles.

News of the Week.

Death of Dr. Oertel.—Telegraphic news reports the death of Dr. Oertel, of the Hygienic Institute of Hamburg, from Asiatic cholera contracted while making investigations of infected water from the Vistula.

Dr. Pliny Earle's Bequest to Leicester, Mass.—The town of Leicester, Mass., has received six thousand dollars under the will of the late Dr. Pliny Earle, for the erection of a building for the public library of the town.

Dr. R. Matas has been appointed Professor of Surgery in Tulane University, New Orleans.

A Forty-five day Fast.—For forty-five days Professor George Sloane, of Chicago, has lived on morphine and mineral water. No food has passed his lips. He began his fast to relieve pain in his stomach.

Li Hung Chang, says his biographer, took a deep interest in medical missionaries, and among his contemplated reforms was the introduction of Western medicine. "If these people," he said to me one day, "ever come into the Chinese heart, the physician will open the door."

The Serum of Asses.—Under the title of a "New Cure for Consumption," a lay contemporary, says the *Medical Press*, announces that Dr. Viquerat, of Geneva, after a long study of tuberculosis, has reached some extraordinary results by a treatment which consists in the subcutaneous injection of the serum of asses. Twenty-seven tuberculous patients of the second and third degree have undergone this treatment; twenty five of these cases, it is said, had been given up by their physicians as lost, but were, it is alleged, entirely cured, the names and addresses of these lucky twenty-five being authenticated by an authoritative report. On the strength of this, it is further stated that a philanthropic Genevan has founded the Viquerat Institute for the treatment of persons whose case is looked upon as hopeless. We fear that our contemporary is the victim of a joke.

Mushroom Colleges.—It is scarcely known on this side of the Atlantic (says the *Medical Press*) how easy a matter it is to found a mushroom college in the United States. In speaking upon this question our contemporary the *Lancet Clinic* recently observed that, "In Ohio any five men can organize and obtain a legal college charter, and with it in six weeks, or six days, can grant a legal diploma. Hence, the only protection for the people, and for the medical profession, is to be found within the medical profession itself." Our contemporary adds: "What a farce! It is difficult to understand how such a deplorable state of things is allowed to persist. Why are not new laws passed, and the medical education of the country placed upon a proper footing? The public would be the first to benefit by the change, and the status of the profession would at once be raised." It is but fair to add that the conditions in Ohio are exceptional, and that in the great majority of the States graduates from such institutions are not allowed to practise.

The Medical Society of Virginia will hold its next annual meeting in Richmond, Tuesday, Wednesday, and Thursday, October 23, 24, and 25, 1894. The subject for general discussion, open to any physician registered in attendance, is appendicitis.

The New York State Association of Railway Surgeons will hold its annual meeting Thursday, November 15, 1894, at the New York Academy of Medicine. All railway surgeons of the United States are invited to attend.

A State Medical and Surgical Association has been organized in Jackson, Miss. A membership of one hundred and twenty names was enrolled. The officers are: Temporary President, Dr. J. H. Lucas, of Greenville, and Dr. H. H. Hughes, Secretary.

The Tri-State Medical Society of Alabama, Georgia, and Tennessee.—The sixth annual meeting of the above Society was held in Atlanta, Ga., on October 9th, 10th, and 11th.

An Excited Practitioner.—A Kentucky doctor writes to the *Louisville Medical Monthly* like this: "The hungry and unprincipled learned physician does more harm than an honest one of less capacity. He tramples upon your feelings; he lies to your people; he makes capital out of your labor; he boldly takes possession of a case when he is accidentally called upon; he introduces a speculum, and tells your patient she has lacerated cervix, from carelessness of her attendant; he calls, or sends wife (who belongs to the same euchre club, or church), to see how she is getting along. You call him in consultation, and he drops in socially afterward, just because he was passing. You can't lance a boil; you must send for the surgeon (who treats measles, whooping-cough, and obstetrical cases). This surgeon is your friend socially, but takes your cases, and when called in your place, tells the family how he would have treated the case if he had seen it in time. A plain case of belly-ache is now a case of appendicitis, and the regular family doctor is 'not in it.' All kinds of ovarian troubles meet with prompt removal at the hands of some so-called specialist. A family doctor can't set a common fracture, and if he does, on his return call he finds this so-called surgeon has taken off his dressing, and has dressed it himself, with the excuse to his friend, the family M.D., that he had to, as the family asked him. You are called to a man hurt in a railroad accident, or at a fire, and spend all night ministering to his sufferings; next morning you are called to the telephone, and notified that the railroad or fire department doctor will take care of your patient, as he is paid by the company, and you can take a walk. I have met with all the above abuses time and again, and I have always kept my temper, remembering a physician should be a gentleman. But I have changed my mind, and this is about what I intend to do: take the next unprincipled doctor by the neck, and make him think that old Drs. Kellar, Gilpin, and Ross are still alive. Yours, etc., F. E. CORRIGAN, M.D."

Pneumatic Tires for Hospital Ambulances.—The makers of hospital ambulances have learned something from the bicycle makers. They are now using the pneumatic tires, which save the jarring and jolting.

Gift to Hospitals.—It is announced from Vienna that Baron Albert de Rothschild has given half a million florins ($250,000), to be called the "Bettina Fund," to the Vienna hospitals. Out of this sum a pavilion is now being built for women suffering from cancer, on the grounds of the Empress Elizabeth Hospital, in the western suburb of Rudolfsheim.

The Mississippi Valley Medical Association meets at Hot Springs, Ark., on November 18th.

The Southern Surgical and Gynecological Association meets in Charleston, S. C., November 13th.

Chicago Medical Colleges Unite.—An alliance offensive and defensive will probably soon be entered into by the Northwestern University Medical School, Rush Medical College, and the College of Physicians and Surgeons, whereby there shall be between these institutions absolute uniformity in respect to entrance regulations, and also in respect to the methods of recording conditions of admission of each member of the class. The primary object of such an arrangement is that each party to the agreement shall promptly inform the other parties of any candidate for admission to the class, so that the other parties shall be protected against accepting rejected candidates. A similar agreement is in a fair way to be consummated between the homœopathic medical colleges of the city.—*Chicago Medical Recorder.*

Hospital for Life-savers.—The Marine Hospital Bureau has issued a circular carrying into effect the law extending the benefits of the marine hospitals to the keepers and crews of life-saving stations. A list of nineteen hospitals where they can be treated is given.

The Doctor's Doorman.—The French papers, says the *British Medical Journal*, are commenting with a kind of awe on the fact that a site in the Rue de Vaugirard in Paris, which was surveyed the other day and valued at 600,000 francs ($120,000), turned out to be property of a former hall porter of Ricord's. That sum certainly represents very pretty pickings, but we have little doubt that the case could easily be paralleled in this country. The august functionary who guarded the portals of a certain court physician used, it is said, to think, like the Emperor Titus, that he had lost a day when he did not pocket six or seven sovereigns in "tips;" another estimated his revenue from what he playfully called the "guinea bell" at £600 a year; a third ran his master (a celebrated specialist now deceased) as if he were a show, and had a regular scale of prices for admission, with reserved seats—on the stairs or in the hall opposite the great man's door—and other special privileges for such as cared to pay for them. This sort of thing is still, we believe, a custom of the effete East.

The Fauna of Dead Bodies.—M. Mégnin, in a work presented to the Paris Academy of Medicine on the fauna of dead bodies, indicates the importance of these entomological studies with regard to medical jurisprudence. The insects appear in relays according to the period of putrefaction. The first which appears is the musca curtonea and callophora. It is present on dead bodies buried in the most careful manner. The eighth group, coleoptera, are found in dead bodies which have been buried four years. The dust that remains after the decomposition of the body is really the excreta of these animals.

A French Physician, Dr. Grellety, advises doctors to marry a pretty woman without vanity, an intelligent woman who does not make too great a display of what she knows, and above all an amiable one. If this seems too much, profound love will make up for many deficiencies.

A Busy Doctor.—A Swiss doctor is said to have counted his steps by a pedometer last year. The total was 9,760,900, or an average of 26,740 daily. This makes about fifteen miles a day.

Female Education at Johns Hopkins.—The remarks of Dr. Osler at the recent dinner of the Harvard Medical Alumni Association that 33.3 per cent. of the women medical students at the Johns Hopkins Medical School has been married at the end of the first session, has been gravely quoted by the medical press as a failure in co-education. Dr. Osler very properly asks what will happen at the end of the fourth year? The remaining two women in the class stand a poor show of graduating.—*Maryland Medical Journal.*

Gift to a Hospital.—The sons of the late Frederick Billings, of Woodstock, have made the generous gift of $5,000 for the endowment of a free bed in the Mary Hitchcock Memorial Hospital at Hanover. This is in memory of their honored father.

Wanted Doctors in State Hospitals.—The State Civil Service Commission finds great difficulty in securing competitors for places on the medical staff in the various State hospitals. The statutes provide for the appointment at each hospital of a woman physician at a salary of $1,200 per annum, with maintenance. There are also various places on the medical staff of the several hospitals with salaries ranging from $800 to $2,000 per annum, with board. Each hospital also employs an apothecary. Vacancies occur in these places from time to time, and but few candidates appear for the examinations. There is not an eligible list at present from which apothecaries can be appointed, and the commission ordered an open competitive examination of all applicants to be held at its offices in the Capitol, Wednesday, October 3d, at 10 A.M. The salary paid in this place is from thirty dollars to fifty dollars a month, together with board.

The Placarding of "Animal Extracts" on the public bulletin boards of the city will awaken the keenest skepticism as to their real utility.

The Chief Subjects for Discussion at the French Medical Congress to be opened at Lyons on October 25th will be the Etiology of Diabetes, the Clinical Value of the Chemical Examination of the Gastric Contents, and Aphasia. The President of the Congress will be M. Gailleton, Professor in the Medical Faculty of Lyons and Mayor of the city.

Professor Billroth's Widow.—The Emperor of Austria has granted to the widow of the late Professor Billroth a yearly pension of 2,000 florins. This is to be interpreted as a mark of special favor, because according to the law of Austria the pension allowed to widows of professors is only 600 florins. The distinguished surgeon is understood to have left little or no private fortune.

The Quarters for the Board of Health.—On September 29th the City Health Department moved from its old quarters in the building on Mott Street, which it shared with the Police Department for many years, to the new Criminal Court Building on Centre Street, adjoining the Tombs prison. In its new location the Board of Health will have much more ample accommodations than in its former quarters, and the facilities for the proper discharge of its functions will be greatly increased. Fourteen rooms have been assigned for its use on the ground floor of the building, nine on the second floor, and two on one of the other floors.

Unveiling of the Statue of Dr. J. Marion Sims.—It is proposed to unveil the bronze statue to Dr. J. Marion Sims on Saturday, October 20th, at 3 P.M., in Bryant Park, N. Y. Full details of the ceremonies will be given in our next issue.

Dr. Augustin H. Goelet, of this city, has been elected Associate Fellow of the Philadelphia Obstetrical Society.

The Health of the Czar.—Now it is known that the Czar is suffering from contracted kidney. His disease is consequently incurable.

Unveiling of the Sims Statue.—On November 20th, at 3 P.M., it is proposed to unveil the statue of the late Dr. J. Marion Sims, and formally present it to the city. It will be placed on the north side of Bryant Square, where the dark granite pedestal has already been completed. Addresses will be delivered by his Honor the Mayor of New York, Dr. Paul F. Mundé, Dr. George F. Shrady, and others. The profession is cordially invited to attend.

Obituary.

WILLIAM A. M. WAINWRIGHT, M.D.,

HARTFORD, CONN.

William Augustus Muhlenberg Wainwright, of Hartford, Conn., the well known and highly esteemed physician and surgeon, accidentally shot himself while examining a revolver Sunday, September 23, 1894. The ball passed through the body, seriously wounding the liver, mesentery, and small intestine. Conscious to the last and fully appreciating the nature of his injury, he placed himself in the hands of his associate surgeons of the hospital for an operation, which from the first was hopeless excepting to prolong his life. He died about 4 P.M. the following day, twenty-seven hours after the accident.

Dr. Wainwright was born in New York City, August 13, 1844, the youngest child of Bishop Jonathan Mayhew Wainwright. Graduated from Trinity College, Hartford, in 1864, he received his medical degree from the College of Physicians and Surgeons, New York, in 1867, and after two years service in the New York Hospital, settled in Hartford, where he has continued in practice.

A member of his city, county, and State medical societies and the American Medical Association, he was always ready to assist in advancing the interests of his profession. He was President of the Hartford County Medical Association in its centennial year, and delivered an address upon its celebration of that event. At the time of his death he was Visiting Surgeon of the Hartford Hospital, and Medical Visitor of the Retreat for the Insane.

A handsome man of commanding presence, of scrupulous honesty and strict integrity, he was successful in social circles, while his keen perceptions, good judgment, and skilful treatment made him a leader in his profession.

His widow, two daughters, and two sons survive him. The eldest son, now a senior in Trinity College, purposes to follow his father in the profession of medicine.

Society Reports.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

Fourth Annual Meeting, held in New York, September 25, 26, and 27, 1894.

First Day, Tuesday, September 25th.

The meeting was called to order by the President, Dr. W. J. Herdman, of Ann Arbor, Mich., who stated in his address that the function of the Association was to improve and standardize electrical apparatus, to improve electrical nomenclature, and to assist in fixing a uniform standard of electrical measurements. By appointing each year committees, whose duty it was to report on special scientific questions, it had been possible to accomplish a vast deal of systematic work, which must inevitably prove in time of great aid and benefit to the general profession.

Dr. William James Morton, of New York, Chairman of the Committee on Standard Coils, stated as his opinion that an induction apparatus suitable for the needs of any physician would comprise, 1, a standard cell; 2, a primary coil of half an ohm resistance, made of No. 22 wire; 3, a vibrator of the reed type; and 4, a secondary coil of No. 32 wire, about five hundred metres in length. Such a coil would give the two effects required —muscular contraction and sedation.

Dr. A. H. Goelet, of New York, said that an apparatus which would answer the purposes of the neurologist would not be suitable for the gynecologist on account of the much lower resistances encountered in the latter class of work. He therefore believed that to be generally useful a medical induction apparatus should have a combination of coils of wire of different lengths and sizes.

In the discussion which followed, the opinion seemed to prevail that the most suitable apparatus of this kind for the physician would be one having two different coils.

The Committee on Standard Meters presented its report through Dr. Margaret A. Cleaves, of New York. After describing minutely a careful series of tests which had been made with a dozen or more milliampèremeters made by well known manufacturers, the committee recommended that for ordinary use the meter should register up to one hundred milliampères, and should be of the horizontal type. A double scale was desirable on the more costly instruments, and all meters should be re-calibrated once a year. To obtain greater clearness of the scale it was recommended that the meter should read only in one direction. The question of the value to the physician of knowing the energy used, in addition to the rate of flow, had been considered by the committee, and the opinion was expressed that, whereas the wattmeter was a very delicate and expensive instrument, and the voltmeter and ammeter had their individual values, it was better to use them in connection, and establish by an easy mathematical calculation the number of watts used, or fraction of an electrical horse-power in a given treatment. This point had been established by a series of observations made by the chairman of the committee.

Physics and Current Distribution of the Constant Current.—Mr. W. J. Jenks, M.A.I.E E., of New York City, in this paper gave a historical sketch of the methods of distributing the current employed in the various systems of electric lighting, and also the probable distribution of the current when criminals were executed by electricity. Electricity, he said, was not a source of energy, but only an intermediary agent, and the chief point to be considered in its distribution was the one element of pressure. In conclusion, he offered the suggestion that the varying resistances of the human body might eventually be made a means of diagnosis.

Dr. J. H. Kellogg, of Battle Creek, Mich., said that this thought about turning the varying resistances of the body to account in diagnosis had also occurred to him a few years ago, but on attempting to put it in practice he had found such great variations in the thickness of the skin in different individuals, and that such a large proportion of the entire body resistance was due to the skin itself, that he had abandoned the method as impracticable.

The Physiological Effects of the Constant Current.—Professor A. E. Dolbear, of Tuft's College, Boston, then read a paper with this title. He said that in a magnetic field all the molecules were acted upon by a pressure tending to twist them into new positions. Dr. Frederick Peterson, of New York City, and Professor A. E. Kennelly, of Philadelphia, had failed in their interesting experiments with magnets to observe any appreciable effect on the human body, even though the brain were placed in the field of a very powerful magnet. But these experiments did not necessarily prove that such magnets exerted no influence on the human body; in fact, as the brain itself was not a sensitive organ, why should we expect that it would be affected by a powerful magnetic field? The reason these experimenters failed to detect any magnetic effect on the body might have been that the stress was exerted upon the molecules only. A constant pressure producing no muscular movement could hardly be expected to produce a sensation. The author's opinion was that the effect of magnetism was to produce a diminution of sensitivity, and that theoretically the human body might be considered to be a mass of atomic magnets. He would entirely disassociate magnetism and chemical affinity.

The Therapeutic Uses of the Constant Current in Gynecology.—Dr. G. Betton Massey, of Philadelphia, then read a paper on this subject. He believed that the chief and initial lesion in the majority of uterine and peri-uterine diseases was a catarrhal condition, and he found the constant current the best of all remedial agents for the treatment of catarrhal hyperplasias.

Ultimate Results of Conservative Electrical Treatment in Gynecology—Consecutive Pregnancies.—Dr. George Apostoli, of Paris, sent a communication with the above title. The writer stated that the constant current was often an effective substitute for the curette, not only on account of the ease with which the degree and extent of the action could be controlled, but because of its microbicidal power. The electrical treatment of uterine fibroids was purely symptomatic, yet with it hemorrhage could be controlled in ninety per cent., the pain relieved in eighty per cent., and the fibroids reduced in size in seventy per cent. of the cases. Although his patients came to him at an average age of from thirty-five to forty-five years, and often with fibroids, a very considerable proportion had become pregnant subsequent to the electrical treatment. A detailed account of thirty-two such cases was appended to the paper.

The Electro-therapeutics of Diseases of the Eye.—Dr. L. A. W. Alleman, of Brooklyn, N. Y., read a paper in which he detailed the especially favorable results he had obtained from the use of the constant current, 1, in the removal of eyelashes which irritated the eyeball; 2, in granular conjunctivitis; 3, in stricture of the lachrymal duct; 4, in keratitis and opacities of the cornea; and 5, in retinitis diabetica and retinitis pigmentosa.

Dr. M. A. Cleaves added to this list the report of a case of optic atrophy treated by the constant current, with improvement in vision but no changes in the fundus.

Second Day, Wednesday, September 26th.

The Action of Electricity on the Sympathetic.—Dr. A. D. Rockwell, of New York, continued the consideration of the effects obtained from the constant current by presenting a paper on "The Action of Electricity on the Sympathetic." The paper dwelt more particularly

on the results of his experience with electricity in the treatment of exophthalmic goitre and hyperidrosis.

In the course of the discussion Dr. A. Lapthorn Smith, of Montreal, and Dr. F. B. Bishop, of Washington, D. C., cited instances in which the patients show a very strong tendency to syncope during the treatment. Most of the speakers were agreed as to the decided efficacy of the constant current in the treatment of goitre, but Dr. J. J. Putnam, of Boston, did not think it so generally useful in these cases, and expressed the belief that statistics seemed to show that better results were obtained, at least so far as giving prolonged relief from the symptoms, by surgical operation.

Notes on Goitre, and Improvements in the Apparatus for its Treatment was read by Dr. Charles H. Dickson, of Toronto. This communication was supplementary to two or three others on the same subject which had been presented by the writer at previous meetings. In the early stages of simple hypertrophy a current of 100 to 150 milliampères should be given for ten minutes at a time, a clay electrode being applied over the goitre, and a large wire gauze electrode between the shoulders. When puncture is resorted to, one should not be content with a current of less than 50 milliampères applied for eight or ten minutes, and care should be taken to observe antiseptic precautions, and to see that the portion of the needle outside of the capsule is thoroughly insulated. In his experience, the pure cystic goitres had proved to be the most amenable to treatment. His method was to aspirate the contents of the cyst, inject a hot solution of chloride of sodium (one drachm to the ounce), apply through the trocar a current of from 50 to 100 milliampères for ten minutes, and then withdraw the salt solution. It should be remembered that puncture alone involves some risk, and that change of residence and attention to hygiene are important adjuncts to all forms of treatment.

Dr. Robert Newman, of New York, referred to a method of treatment which was employed by Dr. Watkins, of New York City, with good results. A needle was connected with each pole of the battery, and currents of only from one-fourth to one-half a milliampère were found to answer.

Dr. Rockwell objected to the strong currents advised by Dr. Dickson.

Dr. Morton said the object of using these strong currents was to secure adhesion of the cyst walls, but the same object could be attained with a current of only 5 or 10 milliampéres by calling to our aid metallic electrolysis.

Metallic Electrolysis.—This was the subject of a brief communication from M. Gautier, of Paris, and also of a paper by Dr. William James Morton, of New York. The latter detailed some experiments regarding the diffusion into the tissues of the metal dissolved from the electrode. He had found that the apple-green color of the tissues after cupric electrolysis was due to an interstitial deposit of an amorphous insoluble salt of copper, and that there was also a soluble salt of copper deposited in the tissues. His experiments had also shown that soluble electrodes might be used with the negative pole, one of the best metals for such a purpose being aluminum. Among the clinical adaptations of metallic electrolysis might be mentioned its prompt and curative action in trachoma.

Dr. Goelet also made some remarks on the clinical uses of metallic electrolysis, particularly as to the great value of zinc electrolysis in uterine disease. The good effect of the treatment as regards arrest of hemorrhage may not be apparent for some time.

Dr. Holford Walker, of Toronto, emphasized its delayed action in arresting hemorrhage by citing a well-chosen illustrative case.

Dr. O. S. Phelps, of New York, reported a case of long-standing and obstinate mucous cyst of the tongue which he had quickly and permanently cured by cupric electrolysis. He also exhibited some elliptoid electrodes which he had had made of hard rubber covered with copper, thus diminishing their weight, and rendering them more susceptible of delicate manipulation.

The President said that his experience with metallic electrolysis had been in the treatment of inflammations of the mucous membranes, and he thought that its power of reaching into the innermost recesses of the tissues made it particularly valuable in the treatment of gonorrhœa.

Dr. William James Morton, Chairman of the Committee on Standard Electro-static or Influence Machines, reported that the committee recommended that the smallest machines of this class intended for medical work should have at least six revolving disks twenty eight inches in diameter, instead of four disks, as recommended last year. It was considered necessary that the machine should have an enclosing case, and highly desirable that there should be a small separate exciting machine within the case, and also an arrangement for producing the static induced current.

Dr. Lucy Hall-Brown, of Brooklyn, N. Y., then exhibited a stand and universal electrode which she had devised, and which greatly facilitated the giving of static electricity.

Dr. M. A. Cleaves exhibited a form of water rheostat which she had had constructed for the purpose of controlling the static induced current at a distance from the machine.

A Report to Date of the Treatment of Urethral Stricture by the Constant Current was read by Dr. Robert Newman. The report stated that his further experience had only served to confirm his former statements and observations. In some instances the patients had been kept under observation for eleven years. In proof of his claim he submitted statistics and documentary evidence from practitioners in various parts of the country.

The paper was discussed by Dr. Beaver, of Reading; Dr. Frank Ross, of Elmira; Dr. F. B. Bishop, of Washington, D. C.; and Dr. Wallace, of Boston, all of whom spoke highly of this treatment from their personal experience. Several of the speakers contended that equally good, if not better, results were obtained from the use of the ordinary urethral sound as from the bulbous-tipped instrument recommended and used by Dr. Newman. The latter, however, stoutly contested this point, asserting that his instrument allowed of greater delicacy of manipulation, and a more perfect localization of the current at the seat of stricture.

The Behavior of Cancer under Mild Galvanic Currents.—Dr. R. J. Nunn, of Savannah, reported the case of a lady, aged sixty, in whom he had succeeded in greatly reducing the size of the carcinoma of one breast by mild percutaneous applications of the current. She then drifted away into the hands of some faith curers. At the time she left him the tumor measured two by two and a half inches, but on her return to him five months later it measured fully thirteen inches in circumference, and there were secondary deposits in the other breast, and in the pelvic and abdominal viscera. The treatment was resumed, and with benefit, but she eventually died of the disease. His special object in reporting the case was to show the effect of such mild currents in a case in which the diagnosis of cancer was beyond a doubt.

The President also related his experience in the treatment of tumors by electricity. It tended to show that some tumors of the breast, either benign or of doubtful malignancy, might be rapidly dissipated, but that when the diagnosis of malignancy was beyond dispute there was nothing in such treatment which could be considered at all curative.

Hydro electric Methods, Physics and Appliances.—Mr. H. Newman Lawrence, M.I.E.E., of London, read the paper. After speaking of the importance of using well made and carefully installed apparatus, he stated that nothing surpassed the electric douche for

giving the maximum of concentration and localization of the current with the minimum of pain, and expressed the belief that it was particularly suitable for the electrization of the internal cavities of the body. The resistances to the current increased greatly as the temperature of the water decreased. In the dipolar bath only a small proportion of the current passes through the patient.

The Hydro-electric Therapeutics of the Constant Current.—A communication was then read from Dr. W. S. Hedley, of Brighton, England, on this subject. He said that the temperature of the bath should be between 90° and 104° F., and a faradic current should be allowed to flow for a few minutes before the patient leaves the bath. He had obtained his best results with this treatment in rheumatoid arthritis.

Special Hydro-Electric Appliances.—Dr. M. A. Cleaves followed with some remarks on this subject. She described Boudet's excellent method of treating occlusion of the bowel, and exhibited electrodes for making such applications to the bladder, rectum, pelvic tissues, ear, and nose. This was the most important method of employing cataphoresis, and perhaps in no disease was its good effects so apparent as in the treatment of gonorrhœa by hydro-electric applications. With her new water electrode, a description of which appeared very recently in the Medical Record, a douche could be given, and pelvic exudates thus brought more effectually under the influence of the current than by the more usual intra-uterine galvanic treatment. In conclusion, the author detailed some observations she had made, which gave not only the number of watts or electrical horse-power used, but also the number of joules.

Third Day, Thursday, September 27th.

The Effects of High Frequency Discharges.—Professor Elihu Thomson, M.A.I.E.E., of Lynn, Mass., sent a communication on this subject, in which he stated that if a person were subjected to a current of over ten thousand alternations per second, and a voltage of one hundred or two hundred thousand, comparatively little sensation would be experienced, although the heating effect might be sufficient to bring a 110-volt incandescent lamp to full brilliancy. Its comparative harmlessness he had demonstrated to be due not to its physical properties but to physiological peculiarities of the nerves of the human body.

Some Experiments on Death by the Alternating Current.—Professor Edwin Houston read a paper, prepared by Professor A. E. Kennelly and himself, on this subject. The object of the experiments was to refute the startling assertion made by M. D'Arsonval that the criminals condemned to death in the electric chair were not really killed by the electricity, but subsequently by the post-mortem examination. Their experiments seemed to show that at least in the case of dogs, where electrocution was properly carried out, there was not even a remote possibility of subsequent resuscitation, and that death was instantaneous and painless.

The Treatment of Neuritis by the Galvanic Current.—Dr. Landon Carter Gray, of New York, read a paper with this title. He advised waiting three or four weeks if a motor nerve were involved, or if a sensory or a mixed nerve were affected, until the pain had entirely subsided, and then experimentally and very carefully apply a galvanic current of from one quarter to one milliampère. It was important to use a broad electrode above and beneath the affected nerve, and to use a reliable rheostat and milliampèremeter. The discussion seemed to show a general unanimity of opinion regarding the recommendations made in the paper.

Sinusoidal Current.—Dr. J. H. Kellogg, in treating of the "Physiological and Therapeutic Effects of the Sinusoidal Current," stated that with fourteen thousand to sixteen thousand alternations per minute he had observed a decided diminution in the sensibility of the parts to which the current was applied, so much so that in ten minutes the strength of the current could be doubled without producing increased sensation. He considered the faradic current in every way inferior to the sinusoidal current.

Dr. Morton remarked that in actual practice he had found this current particularly useful for treating children, as it did not hurt or frighten them, which could not be said of any faradic current, however skilfully applied.

Dr. Walker was also loud in praise of the sinusoidal current.

Dr. Goelet thought it was not as distinctly tonic as the faradic, or so generally useful.

Dr. Hall Brown described a method which she had devised for controlling and regulating the sinusoidal current as obtained from certain electric lighting circuits. Almost any induction coil would make a suitable transformer for this purpose, but such an apparatus was preferably constructed of one layer of No. 20 wire for the inside coil and ten layers of the same wire for the outside coil.

The following papers were also read, but they were of such a nature as not to admit of being presented in abstract: "Some Landmarks in Electro-therapeutics," by Dr. O. S. Phelps, of New York; "Some Therapeutics of the Incandescent Electric Light," by Dr. J. H. Kellogg, of Battle Creek; "On Constant Current Generators and Controllers," by Dr. W. J. Herdman, of Ann Arbor; "General Faradization," by Dr. A. D. Rockwell, of New York; "Electric Light as a Therapeutic and Diagnostic Agent," by Dr. Margaret A. Cleaves, of New York; "Physics of the Sinusoidal Current," by Professor A. E. Kennelly, of Philadelphia; "Physics of the Static and Static Induced Current," by Professor Edwin Houston, of Philadelphia; "The Transformation, Measurement, and Therapeutic Applications of Alternating Currents," by MM. Gautier and Larat, of Paris; "The Physiological Effects and Therapeutic Uses of the Static Induced Current," by Dr. W. J. Morton, of New York; "The Electric Reaction of Muscles and Nerves after Great Exercise in Sport," by Professor J. Benzonie, of Bordeaux; and "Secondary Peripheral Neuritis in a Stilt-walker," by Professor J. Benzonie and his assistant, H. Bordier, of Bordeaux both of the Faculty of Medicine of Bordeaux.

Dr. A. Lapthorn Smith, of Montreal, was elected President, and Dr. Emil Heuel, of New York City, Secretary for the ensuing year.

Ingenious Plea of a Quack.—A man was recently tried in France for the illegal practice of medicine, the charge being that he sold Matlei's magnetized water. He entered the plea that he employed a remedy which physicians had declared to be nothing but water and entirely innocent of therapeutic effect, and that he could not therefore be accused of practising medicine in the ordinary acceptance of the term. The learned Tribunal admitted the force of the prisoner's plea, and set him at liberty.

The Number of Marriages in England is on the increase, the first quarter of 1894 showing the highest rate of any like period, with but one exception, since 1883. In the first three months of this year there were 93,366 weddings, corresponding to an annual rate of 12.9 per 1,000 of the estimated population. This is not less than 18.3 per cent. above that in the first quarter of 1893, which was 10.9, and the lowest on record. It exceeds the mean rate in the corresponding quarters of the ten years 1884–93 by 9.3 per cent., and is the highest in the first quarter of any year since 1883, except that of 1891, when it was 13.7. The Registrar-General points out that this is the more remarkable, inasmuch as in the last quarter of 1893 the marriage rate had been 6.9 per cent. below the average rate in the December quarter of the previous ten years.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Proceedings of the Twenty second Annual Meeting, held in Montreal, September 25, 26, 27, and 28, 1894.

FIRST DAY, TUESDAY, SEPTEMBER 25TH—MORNING SESSION.

THE PRESIDENT, DR. E. P. LACHAPELLE, OF MONTREAL, IN THE CHAIR.

THE Association met in the Hall of the Y. M. C. A., and was called to order at 10 A.M. by the President.

DR. ROBERT CRAIK, of Montreal, reported on behalf of the Local Committee of Arrangements a very attractive programme. He also announced the social features of the meeting. The Committee had arranged for trips over the Lachine Rapids and down the St. Lawrence to Grosse Isle.

The reading of papers was next proceeded with.

Hygienic Notes made on a Journey through Italy in 1894.—DR. H. F. NUTTALL, of Baltimore, contributed a paper on this subject, which was read by DR. A. L. GIHON, in the absence of the author. This paper described the sanitary conditions, particularly in reference to water-supply and sewage, of Rome, Naples, Venice, and other Italian cities. In Naples poverty and ignorance provided an easy prey to every epidemic until 1884. But after the cholera epidemic of 1884 the Government resolved to spend one million francs for sanitation. New sources of water-supply were secured, new sewers built, and whole blocks of tenements were torn down and replaced by modern houses. The result has been to impart habits of cleanliness to the people and to greatly reduce the death rate.

The Cart before the Horse, by DR. BENJAMIN LEE, of Philadelphia. The object of the paper may be briefly embodied in the two following propositions: 1. Copious water supplies, with the aid of what is known as modern plumbing, constitute a means of distributing fecal pollution over immense areas through the soil, through subterranean water courses, and in surface streams, and cannot therefore be regarded with unmixed approbation by the sanitarian. 2. The question of drainage and sewerage, whether for individual residences or for communities, should always precede that of water supply; and no water-closet should ever be allowed to be constructed until provision has been made for the disposition of its effluent in such a manner that it shall not constitute a nuisance prejudicial to the public health.

Observations upon Sedimentation in Water.—DR. WYATT JOHNSTON, of Montreal, read a paper with this title. The amount of settling which takes place in what is called the settling basin of the Montreal Water-works is too small to be seriously considered. The capacity of the basin being only twenty-three million gallons and the daily consumption about eighteen millions, the water really only passes in and out of the basin. In the reservoir the change in the water is also very rapid, although not to the same degree, for similar causes. However, analysis proves that bacteria are far less numerous in the reservoir water than in the settling basin. The melting of snow in the spring has a tendency to increase the number of bacteria in the reservoir water. As to the value of sedimentation from a hygienic point of view, it is much below that of a sand-filter.

The Long Island Water-basin, Brooklyn's Reservoir, by DR. A. N. BELL, of Brooklyn. After a lucid description of the basin, the author said that while the waste of streams is enormous, it is nevertheless easy to appreciate, from a knowledge of the conditions of the soil and the wells sunk in it, the inexhaustible adequacy of the Long Island water-basin to supply water sufficient to meet the demands of Brooklyn for all time.

The Water of our Farm Homesteads.—DR. FRANK T. SHUTT, of Ottawa, Canada, contributed a paper on this subject. During the past six years the chemical department of the Dominion experimental farms has examined some hundreds of samples of water from wells on Canadian farms, and the fact has been impressed upon the writer that the evil of polluted water is a lamentably common one throughout the country districts, both in the villages and on the farms. The only method the speaker knew for lessening this evil was by instruction and advice, by first emphasizing the great danger that lies in using water polluted with excreta or drainage from filthy sources, and, second, to teach the people that pure water is as much a necessity for the farm animals as for man. Third, farmers must be cautioned against sinking wells in barnyards, stables, or near the pig-pen or privy.

Sand Filtration of Water, with Especial Reference to Recent Results Obtained at Lawrence.—MR. GEORGE W. FULLER, of Lawrence, Mass., followed with a paper with this title. While the removal of pathogenic bacteria by chemicals, including coagulants and by heat, will forever be directly dependent upon human attention, he ventured to predict that the day will come when a knowledge of filtration among sanitary scientists will be such that filters may be constructed and operated by which water free from objectionable bacteria will be supplied to hundreds and thousands of citizens and require the attention of only a mere handful of men. During the five years preceding the use of the filter at Lawrence, the average annual death-rate from typhoid fever in Lawrence was 1.27 per 1,000 inhabitants. The population of Lawrence is 50,000, and this average is equivalent to 63 actual deaths per year. During the past year there have been 26 deaths from typhoid fever, a reduction of sixty per cent. Furthermore, it has been learned that of the 26 who died 12 were operatives in the mills, each of whom was known to have drunk unfiltered and polluted canal water, which is used in the factories at the sinks for washing. In conclusion, it has been found practicable to protect the consumers of infected water-supply by means of sand filtration.

Some Deductions from Bacteriological Work on the Water of Lake Ontario.—This paper was by MR. E. B. SHUTTLEWORTH, of Toronto. It dealt with the normal bacteriological character of Lake water and the depth of water as affecting the number of bacteria, and the author is inclined to think that the number of bacteria is directly influenced by season. He is convinced that in their nature certain micro-organisms multiply most rapidly at certain seasons of the year. He threw out the suggestion that this may have an important bearing in explaining the prevalence of typhoid fever at certain times during the year. This seasonal peculiarity is very well marked in Toronto, when every September shows a sudden increase in the typhoid rate, with a corresponding decline after October. Since May last he had been paying attention to the temperature of tap-water, which seems to be related to the development of this disease. He hoped in the future to throw some light on this subject, as the experiments of numerous investigators had shown that it is possible for micro organisms to exist and multiply enormously in distilled water, or, at all events, containing only the minutest traces of organic matter.

AFTERNOON SESSION.

The Pollution of Water-supplies.—DR. CHARLES SMART, of Washington, D.C., Chairman, read the report of the Committee on the Pollution of Water-supplies. The report reviews at length the influence which a polluted water-supply may have had in the recent cholera epidemic in Europe, and upon the spread of typhoid fever on both continents. The efforts to purify water by sand filtration were also reviewed, wherever made, and the report concludes: "From this brief review of facts and opinions concerning filtration, it will be seen that your committee hesitates to reaffirm its former positive language with regard to the sufficiency of filtration as protection against typhoid fever. Nor, on the other hand, do we regard the testimony as authorizing a formal declaration of opinion in favor of the efficiency

of filtration. Our experience in this country is extremely limited, but it is hoped that the success achieved at Lawrence will lead to the filtration of other surface waters, each of which will probably teach an important lesson in connection with bacteriological experiments and with the mortality from typhoid fever before and after the construction of the filter beds. In view of an unbroken record of typhoid fever in communities that use raw river-water, and an equally unbroken record of lessened typhoid rates following the filtration of such river supplies, your committee considers that in Washington, D.C., special attention should have been given to the improvement of the general supply. This country needs some practical lessons in methods of water purification."

At the conclusion of the report Dr. Gardner, of London, Ontario, offered the following resolution:

Resolved, That in view of the danger to the public health by the sewage contamination of our fresh-water lakes, rivers, and streams, this Association memorialize the different Federal Governments, as well as the State and Provincial Governments, to pass laws prohibiting the contamination of these water-supplies by sewage from cities, towns, and villages, and compel them to provide some means for the treatment and oxidation of this sewage before emptying it into these places.

The resolution was referred to the Executive Committee and subsequently adopted by the Association.

Management of Diphtheria Epidemics in Rural Districts, by Dr. Charles A. Hodgetts, of Toronto. The medical officer must exercise a personal supervision not only over his patients but personally superintend the carrying out of all orders, for upon the thoroughness of the work depends to a very large extent the prevention of further outbreaks in the district. He felt the inhabitants of the rural districts should receive more attention from the sanitary authorities than they had heretofore, and some inexpensive system should be adopted for the more efficient and prompt management of epidemics in those portions of our country. Schools should be closed in the district until such time as the inspector has satisfied himself in the manner indicated that the household of the individual scholars thereof are free from diphtheria.

Practical Difficulties of Medical Health Officers and Physicians in Dealing with Suspected Cases of Diphtheria was the title of a paper read by Dr. Peter H. Bryce, of Toronto. With every advance in our knowledge we find that the practical benefits are often limited by unforeseen difficulties, and that bacteriological results bring into prominence the difficulties which the health officer finds in dealing with cases of sore throat, and which may be summed up as follows: 1. That according to recent investigations made, at least twenty-five per cent. of diphtheria cases are not caused by the Loeffler bacillus. 2. That physicians endeavor to hide cases in the supposed interest of the client, and conveniently shield themselves behind the assertion that they could not tell whether the disease was diphtheria or not. The author drew special attention to the difficulty of differentiating between cases of ordinary sore throat and real diphtheria. It was impossible often to decide that cases were really diphtheria without microscopic examination.

Dr. J. Ed. Laberge, of Montreal, read a paper in French, entitled "Vaccination as a Preventive of Contagious Diseases." The paper was historical, it being largely a review of Pasteur's experiments.

Innocuous Transportation of the Dead.—This paper was read by Dr. J. D. Griffith, of Kansas City, Mo. The author said that the age demands a far greater protection to the public health. He was convinced that we owe to the travelling public that greater precautions should be taken in the transportation of the dead body. He cited as evidence of the virulence of a dead body that in a Normandy village, twenty-three years after an epidemic of diphtheria, some of the bodies of those who died of the disease were exhumed and an epidemic at once broke out, first among those who opened the grave, and then spread from those to many others. Other examples were cited. Until the public are educated to the point of the thorough sanitation of cremation, the transportation of dead bodies by the railways is, and always will be, a source of very great danger. The speaker urged that the attention of the different legislative bodies of the country be directed by the Association to a subject of such vital importance. He urged, furthermore, that all railways cut off a small portion of their baggage cars for the transportation of dead bodies. The dead body should be placed in a box lined with zinc, with a door very much after the fashion of a large ice chest. This done, the lives of employees would not be endangered; no broken or open box could become infected, and no odor could escape from the car.

Evening Session.

At this session addresses of welcome were delivered by Dr. Robert Craik, the Lieutenant-Governor of the Province of Quebec (Hon. J. A. Chapleau), the Mayor of Montreal, Hon. L. P. Pelletier, Provincial Secretary, and Doctor Gregario Mendizabal, of Mexico, after which the President of the Association delivered his annual address.

The President's Address.—He said the American Public Health Association, since its foundation, now twenty-two years ago, has never ceased to labor for the advancement of sanitary science; for the promotion of measures and organizations that should effect the practical accomplishment of the laws and principles of public hygiene. It has thus realized the brightest hopes and most enthusiastic provisions of its worthy founders, and has extended its benefits and influence over the whole of North America. To-day it embraces the three great countries that form this vast continent—the United States of America, the Republic of Mexico, and the Dominion of Canada—all three working together in brotherly emulation, recognizing no political boundaries, and striving to attain one unique and humane object—the dissemination of all of the knowledge of public hygiene and the development of respect for its decrees. Every year the Association changes its place of meeting, and this for good reasons. The spirit of its founders being to establish a body for the diffusion and popularization of public sanitary science, this object could not be better attained than by extending to its greatest limits the influence of the Association; and for this purpose no surer means could be found than the bringing together of its distinguished members.

President Lachapelle in closing urged the creation by the Government of a new department in their cabinets—that of Public Health.

Second Day, Wednesday, September 26th—Morning Session.

The Executive Committee recommended, which was endorsed by the Association, a new committee, to consist of five persons, entitled "Steamship and Steamboat Sanitation."

Dr. E. Gauvreau, of Ste. Foye, Quebec, described in a paper the process followed in his institution—the Vaccine Institute of Ste. Foye—for the culture and collection of vaccine lymph, showing that every care is taken to insure absolute safety to the public using the points.

Restriction and Prevention of Tuberculosis, by Dr. N. E. Wordin, of Bridgeport, Conn. He showed that consumption was an infectious or communicable disease and that the principal source of danger of its spreading lay in the sputum ejected by a phthisical patient when it had become dry. The breath of a consumptive contained no bacilli, and was not infectious. If the spread of this disease was to be prevented the sputum must be attacked. Phthisis might be communicated by osculation, and

among the hygienic commandments should be one for the syphilitic and the consumptive, "Thou shalt not kiss." He considered that the most practical and the quickest way of restricting the spread of tuberculosis would be to put it on the list of infectious or communicable diseases to be reported to the health officers.

Examination of the Milk-supply for Tuberculosis in the State of New York, by DR. F. O. DONAHUE, of New York City.—He said that in May, 1892, New York State took a step forward in authorizing its Board of Health to make investigations in reference to the existence of tuberculosis in cattle. The relation of the milk-supply to infant mortality from tuberculosis was insisted upon by all health officers who had made it the subject of systematic observation. That milk and its product will convey tuberculosis had been proven. When it is considered that milk is the principal aliment during childhood, and enters largely into the diet of all classes, it was a highly important question for consideration. Statistics of New York State show that for a period of eight years last past, every eighth death was caused by tuberculosis. The State Board of Health evolved the lesson that tuberculosis existed in the dairy cattle to quite an extent, and that special legislation was necessary to deal with it. It is confidently expected that future legislation in this regard will be enacted carrying with it an appropriation commensurate with the magnitude of the work.

Should the Marriage of Consumptives be Discouraged?—DR. PAUL PAQUIN, of Missouri, followed with a paper on this subject. He held that the marriage of a consumptive with a healthy person must lead to the infection of the latter, and that the children born of consumptives are always naturally predisposed to tuberculosis. Thus the centres of infection are increased and the danger to society is made much greater. No consumptive should marry, and it is perfectly proper for science to interfere and use all its influence to prevent such marriages.

The Climatic Segregation of Consumptives.—DR. HENRY SEWALL, of Denver, read a paper on this subject. He proposed the following plan for the treatment of consumption in its early stages, viz., he would establish at favorable points in Colorado a series of cottage sanatoria. The cottage plan was eminently the best in its adaptation to the character of the climate, the people, and the disease. The efficiency and feasibility of such an institution had already been established in the Adirondack Cottage Sanatorium of New York, which might well serve as a model for extensive development. These sanatoria should be located with careful regard to climatological conditions, purity of water supply, beauty of scenery, and accessibility to railways.

DR. JOHN T. NAGLE, of New York City, in some remarks upon diphtheria, said that the Health Department of New York City had been making strenuous efforts to stamp out diphtheria, and with this end it has instructed the bacteriological division to examine gratuitously the cultures furnished it by physicians who attend suspected cases of diphtheria. He said that Dr. Cyrus Edson has great faith in the antitoxine treatment of diphtheria, and it promises to be one of the most important discoveries of modern medicine, and, so far as could be judged from the data at hand, will afford us a means of not only protecting persons from diphtheria who have been exposed to the disease, but also a certain means for the cure of the disease when cases are subjected to this treatment in the early stages. One of the most important and significant features of the treatment depends upon the absolutely innocuous character of the remedy, it having apparently no influence, either favorable or unfavorable, in health or disease, excepting as to its power of neutralizing the poison of diphtheria.

The afternoon was devoted to pleasure, the members of the Association, many of whom were accompanied by their wives and daughters, taking in the trip which had been arranged down the Lachine Rapids.

EVENING SESSION.

DR. F. MONTIZAMBERT, General Superintendent of the Canadian Quarantine, gave an interesting sketch, illustrated by lantern slides, of the quarantine appliances at Grosse Isle. He briefly explained the mode of boarding ocean ships, the examination, disinfection, and hospital treatment.

Some Points in the Hygiene of the Young in Schools.—This paper was read by DR. J. C. CAMERON, of Montreal. He pointed out that mind and body were dependent upon each other, and consequently for the proper development of the individual the body was to be considered and cared for as well as the mind. He referred to the fact that the physical culture of school children was in too many cases improperly cared for, though in the case of boys, who engaged in out-door sports, the effects were not so marked as in girls, who indulged less in out door sports and were inclined to be more sedentary. Spinal curvature and pelvic deformity were liable to result from assuming an improper attitude when sitting, standing, or walking, and consequently it was of the utmost importance that school children should be taught to sit, stand, and walk properly.

Sanitation in Plumbing.—By MR. JOHN MITCHELL, President of the National Association of Master Plumbers, New York. The speaker advocated a semi-annual inspection of all houses for sanitary measures. The rule that at present appears to be observed, he said, is to wait for crape on the door before asking a question regarding the sanitary arrangements.

Influence of Inebriety on Public Health.—This paper was read by DR. T. D. CROTHERS, of Hartford, Conn. The facts he wished to make prominent were:

1. The influence of inebriety on public health is of far greater magnitude and more closely associated with the various sanitary problems of the day than is realized at present.

2. Our present conception of the extent, nature, and character of inebriety is erroneous and based on theories that are wrong. Our methods of dealing with inebriates are most disastrous and fatal in not only destroying the victim, but perpetuating the evil we seek to lessen.

3. These cases must be recognized as diseased, and be housed in farm colonies, under military care and treatment. They must be organized, employed, and placed under hygienic surroundings and made self supporting.

4. The present duty is careful medical study of these classes and full recognition of their needs and requirements. Public sentiment should be built up to sustain rational means and measures in their treatment.

5. The sanitary problems that confront our civilization are very closely associated with the inebriate class. One of the central sources of peril to public health is inebriety. This is the one fountain-head that must be corrected to break up some of the evils of the present day.

THIRD DAY, THURSDAY, SEPTEMBER 27TH—MORNING SESSION.

A Journal of the American Public Health Association.—SECRETARY WATSON read a short paper with this title. He urged establishing a quarterly journal in connection with the Association, to replace the annual volume of Transactions. He expressed the belief that the establishment of such a journal would increase the influence and strength of the Association. The matter was referred to the Advisory Council.

Vaccine and Vaccination.—DR RALPH WALSH, of Washington, D. C., read the paper. He summarized as follows: So-called cow pox is simply modified variola. The admixture of glycerine with vaccine lymph will destroy all extraneous bacteria without injury to its peculiar active principles. The admixture of glycerine with vaccine lymph not only does this, but prolongs the activity of the lymph. The selection of lymph and the simple but important operation of vaccination had not

received from the profession the attention they deserved. The physician should see that each infant brought under his care is successfully vaccinated during the first year of its life, and again at sixteen, or better, to the point of saturation during infancy. The accumulation of unvaccinated material, and consequently the increased danger of outbreaks of small pox, are caused by the general practitioner failing to perform his duty at the proper time.

Car Sanitation.—Dr. G. P. Conn, of Concord, N. H. read the Report of the Committee on Car Sanitation, of which he is chairman. The report maintained that the railway companies are very negligent in this respect. The railway car is virtually and for the time being a house on wheels, in which a varying number of people are expected to make their homes for a longer or shorter period, according to the distance which they may be expected to travel. Therefore, like a house, it should be constructed upon sanitary principles, in which ventilation, heating, and such conditions as will allow it to be kept clean are paramount factors in every case. Unless these sanitary principles can be carried out and made permanent, then this house on wheels becomes unwholesome and unhealthy, and the conditions become favorable to disease, or of spreading it should a contagious or infectious malady find a place within its walls. According to investigations it had been found that the atmosphere of the ordinary coach contained from one to six times as much carbonic acid gas as public assembly rooms, such as churches, theatres, and public halls.

Prevention of the Spread of Yellow Fever.—Dr. Felix Formento, of New Orleans, read the Report of the International Committee on the Prevention of the Spread of Yellow Fever. The report maintained that this plague never originated in Louisiana, but is imported from Cuba, Mexico, and Central and South America. It recommended attempts to stamp out the disease in the swamps in those countries, and the adoption of thorough sanitary measures in the Southern centres, where the disease is wont to become epidemic. An effort to secure the co operation of the governments of Cuba, Mexico, Brazil, and the Central American republics was recommended.

Dr. N. E. Worden, of Bridgeport, read a paper on "Disposal of Garbage," in which he advocated its destruction in an incinerator.

The Disposal of Garbage and Refuse.—The Report of the Committee on the Disposal of Garbage and Refuse was presented by Mr. Rudolph Hering, C.E., of New York City. It dealt with the character of city refuse, its collection and removal from a building to the place of disposal, and the several methods in vogue for its disposal.

Colonel W. F. Morse, of New York, dealt briefly with the collection and disposal of the refuse and garbage of large cities, describing what was being done in New York in order to find out the best method of disposing of its refuse and garbage.

Influence of the Climate of Canada on Health.—This was the title of a paper read by Dr. W. H. Hingston, of Montreal. He touched briefly on the geographical situation and the topography of the country, and then went on to show that after a residence in the country, of shorter or longer duration, a change in the constitution could be observed. The high color which flushed the cheeks of some Europeans faded somewhat, and the skin became less soft, the hair became darker and more like the aboriginal type, and the muscles were less prominent. The hot weather did not last long enough to produce any great disturbance of the liver, and the cold was exhilarating. The ratio of mortality in Canada was lower than that of Great Britain, and, with the exception of Malta, this country was the healthiest station of the British army. Statistics gathered from the States showed that all constitutions were healthier as they approached the Great Northern Lakes.

Afternoon Session.

"The Advisability of Teaching Rules and Principles of Hygiene in the Primary Schools by Means of Object Lessons," was the title of a paper read by Dr. Jesus E. Monjaras, of San Luis Potosi, Mexico.

The Importance of Teaching Hygiene in Elementary Schools.—Dr. S. Gauthier, of Upton, Quebec, followed with a paper on this subject. The speaker held that it was through the teaching of hygiene to the school children that we could eradicate the unfortunate prejudices which directly caused the loss of so many who might have been the strength, glory, and pride of our country.

The Hygiene of Vision in Schools.—Dr. T. D. Reed, of Montreal, recommended the introduction into schools of the suggestions of the Anthropometric Committee of the British Association for the Advancement of Science, in order to test the power of vision and color-sense. He also recommended exercises for the development of the power of rapid and accurate observation.

A Few Remarks on School Hygiene, by Dr. T. M. Brennan, of Montreal. The points in this paper might be summarized as follows: The rousing of the general public to the necessity of propagating the study of hygiene; the hygienic education of children, whose teachers must be proficient in hygiene. In each school there should be a school commission endowed with power to act. There should be some system of efficient general supervision, and the general co-operative support of local and general Boards of Health and the Board of Public Instruction should be assured.

An Epidemic of One Hundred and Twenty Cases of Paralysis in Children.—Dr. Andrew Macphail, of Montreal, contributed a paper on this subject. The paper contained an account of an epidemic of infantile paralysis which occurred in the State of Vermont during July, August, and September, and which the speaker investigated. He first stated that the belief was held that it was an outbreak of cerebro spinal meningitis, but he showed in a lucid manner that it was a true myelitis. He quoted the notes of 91 cases out of the 120. In some children the paralysis came on without any symptoms, in others there was a preliminary illness of a few days resembling indigestion. He described in detail the fatal cases, of which there were 18, and 42 in which there was permanent paralysis. There were also notes of 6 cases in adults, 3 of which ended fatally. He then referred to the origin of the malady, giving full statistics of temperature, rainfall, and humidity, and geological factors. There were, besides, 12 deaths from the same cause among horses, and fowls were likewise affected. In conclusion, he dwelt upon the necessity for having in every State a properly conducted laboratory and a competent staff to deal with such outbreaks, and a Board of Health with authority to investigate epidemics and perform autopsies. The paper had additional interest from the fact that it is the first epidemic of the kind reported in America, and the third which has occurred in any country. The speaker refrained from expressing any views or propounding any theories till the pathological work which he has in hand shall have been completed.

The Advances of Public Health in the City of Montreal was the subject of a paper by Dr. L. Laberge, Medical Officer of Health for Montreal. The author outlined the development of the several matters connected with the public health of the city and the legislation by which they were governed, such as milk inspection, meat-supply, ice-supply, drainage, and public baths. He gave an account of the present state of sanitation in the city, and concluded by showing that during the last twenty years the death-rate had been reduced by 12.87 per thousand.

Myopia in its Relation to School Hygiene.—Dr. A. A. Foucher, of Montreal, presented a chart which illustrated that myopia is more prevalent in the secondary than in the primary schools. In the primary schools of Russia it is fourteen per cent., while in those of Ger-

many, Austria, France, Holland, New Zealand, the United States, and Switzerland it is thirteen per cent.; Norway, eleven per cent.; England, Roumania, and Belgium, thirteen per cent. In the secondary schools in Austria it is thirty eight per cent.; Switzerland, thirty-six per cent.; Germany, thirty-six per cent.; France, thirty-six per cent.; Russia, thirty six per cent.; Denmark, thirty-six per cent. In Italy it is thirty-eight per cent.; Sweden, thirty-four, and in England, thirty-eight.

Dr. G. Mendizabal, of Orizaba, Mex., gave some "Observations on Yellow Fever in Vera Cruz, and its Prevention," and he was followed by Dr. J. I. Desroches, editor of the *Journal d'Hygiene Populaire*, and member of the Board of Health of the Province of Quebec, who discoursed on hygiene in medical education.

Nomenclature of Diseases and Forms of Statistics.—The day's session closed with the reading of the report of the Committee on Nomenclature of Diseases and Forms of Statistics, by Dr. S. W. Abbott, of Boston, chairman. The committee considered changes in the nomenclature and classification of diseases and causes of death; uniform methods of reporting vital statistics; uniform methods of estimating population and death-rates, and the adoption of a standard of age distribution. It is quite plain that a fair comparison cannot be made of the death-rates of countries, cities, and towns in which the age distribution is widely different; hence the importance of adopting some conventional standard to which all populations may be referred, or with which they may be compared.

Fourth Day, Friday, September 28th — Morning Session.

A Plea for Vaccination.—Dr. M. T. Brennan, of Montreal, Can., said vaccination should be performed with all the precautions calculated to insure the action of the pure lymph, free from all contamination and the action of it. Each vaccinator should be provided with —1, pure lymph of a standard strength, if possible; 2, a vial of distilled or boiled water to dilute the lymph; 3, a vial containing a solution of bichloride of mercury; 4, a small alcohol lamp to sterilize the lancet, etc.; 5, Some sterilized absorbent cotton; and 6, some sterilized gauze. All these take up but a small space, and may be placed in a small satchel or metallic case. The operation should be done under strict antiseptic precautions; all instruments, dressings, hands of the operator, etc., should be clean.

Infection by the Bacillus Pyocyaneus as a Cause of Infant Mortality.—Dr. H. Cameron, of Montreal, read a paper on this subject. It was not until 1889 that this bacillus was found to produce definite general infection in young children. The author drew the following conclusions: 1. That the infant tissues are susceptible to the invasion of this bacillus. 2. That the bacillus is distinctly pathogenic, setting up a disease peculiar to experimental pyocyanic disease. 3. That this disease is characterized by a train of very definite symptoms, such as diarrhœa, fever, rapid emaciation, rigidity of the legs, and hemorrhagic and bullous eruptions. 4. That the disease appears to be very fatal.

As this combination of symptoms occurs not infrequently in young children, especially when congregated in nurseries and foundling asylums, the author ventured to infer that a certain proportion of the deaths which now appear upon our records of vital statistics under the headings of gastro enteritis, purpura, or marasmus, were in reality cases of generalized pyocyanic disease.

As to prophylaxis he had nothing definite to offer at present beyond a strict observance of the laws of hygiene, fresh air, suitable nourishment, and cleanliness; but he is inclined to consider that this disease is one eminently suited for a trial of "serum therapeutics." It is a disease in which, experimentally, immunity can be easily produced in susceptible animals. This being so, it is probable that the serum of animals vaccinated against this disease, or substances obtained from such serum, will be found, as in the case of diphtheria, to have curative effects.

The closing paper of the Convention was read by Mr. J. W. Hughes, of Montreal. It was entitled "Evolutionary Developments of Domestic Plumbing during the Past Twenty-five Years."

Several papers were read by title, owing to the absence of the authors.

The following resolutions were offered by C. O. Probst, of Columbus, O., referred to the Executive Committee, and adopted by the Association:

Resolved, That this Association approves the suggestion for a co-operative investigation into the bacteriology of water, and commends the efforts of the committee, in carrying out this work, to the officers of State and Municipal Boards of Health, to the individual members of this Association, and to all persons interested in the purity of water-supplies for such special assistance as they may be able to render.

By Dr. E. R. Campbell, of Bellows Falls, Vt.:

Resolved, That this Association records its protest against the use of alcoholic liquor as a beverage, especially among the young, believing that such use is attended with great danger to the health, the individual, and society.

The Executive Committee failed to act on this resolution.

By Dr. George Homan, of St. Louis:

Whereas, It is the sense of this Association that the pollution of potable waters in America has reached such a point that the national governments should be asked to take cognizance of the matter with the view of devising means of prevention and relief; therefore be it

Resolved, That this Association memorialize the Congress of the United States and ask that they shall authorize the appointment of a competent commission, clothed with power to fully investigate the whole subject of the pollution of rivers and lakes by municipal and manufacturing waste, and provided with sufficient means to enable them to conduct the examination in such a manner as shall be deemed best, the results of said examination to be published from time to time for the public information.

The following officers were elected for the ensuing year: *President*, Dr William Bailey, of Louisville, Ky.; *First Vice President*, Dr. G. P. Conn, of Concord, N. H.; *Second Vice-President*, Dr. G. Mendizabal, of Orizaba, Mexico; *Secretary*, Dr. Irving A. Watson, of Concord, N. H.; *Treasurer*, Dr. Henry D. Holton, of Brattleboro', Vt.

After a resolution of thanks, offered by Dr. A. L. Gihon, of Washington, D. C., the Association adjourned to meet in Denver, Col., at a time to be fixed by the Executive Committee.

Menthol in Itching Affections of the Skin.—Dr. Colombini strongly advocates this drug in cases of eczema of the scrotum, vulva, etc. He uses the following formulæ:

℞. Menthol ..... 5 to 10 parts.
Alcohol ..... 100 parts.

Or,

℞. Menthol ..... 10 parts.
Oil of sweet almonds ..... 10 parts.

Or,

℞. Oxide of zinc ..... 25 parts.
Starch powder ..... 25 parts.
Vaseline ..... 50 parts.
Menthol, from ..... 5 to 8 parts.

Or,

℞. Oxide of zinc ..... 10 parts.
Subnitrate of bismuth ..... 10 parts.
Menthol ..... 1 to 30 parts.
Starch powder ..... 1 to 30 parts.

When the application is to mucous surfaces the mixture should contain a smaller proportion of menthol.—*La France Médicale.*

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

DR. THORNE THORNE, C.B.—APPRECIATION OF MEDICAL WORK FOR THE STATE—THE DUKE AND THE ARMY DOCTORS—CHOLERA—REPORT OF LOCAL GOVERNMENT BOARD'S MEDICAL DEPARTMENT.

London, September 22, 1894.

Dr. Thorne Thorne, C.B , has received from the Queen an intimation of Her Majesty's appreciation of the services rendered by the Medical Department of the Local Government Board in the measures taken to prevent an invasion of cholera. It is reported that the Queen has all along manifested particular interest in the efforts to prevent an epidemic, and this expression of appreciation of the work done will no doubt be gratifying to the principal medical officers. To the profession it might have appeared more satisfactory had the opportunity been taken to give a step in the Order of the Bath. There is always considerable reluctance to convert a C.B. into a K.C.B., especially in the case of medical holders of the dignity. Perhaps this also is due to the absurd jealousy of "military advisers," a jealousy which continues to work untold injustice. No one doubts that the Duke of Cambridge has greatly injured the army medical officers by his silly jealousy of the non combatants, but he has lately had a lesson on the drift of public opinion he would do well to take to heart. He has been pushed into good things because of his birth, not because of his knowledge or skill—the Crimea proved that—and he should have some regard for those who make their way by skill and knowledge only. If he continues to persecute non-combatants (*e.g.*, the case of Dr. Briggs) the day of reckoning may be nearer than he imagines.

To return to cholera. The disease has in some parts of Europe been more severe this year than last, and the danger which has threatened England has been greater, too, as it has manifested a disposition to spread in different directions. In Russia and Galicia it has been more fatal, and still prevails. The returns from St. Petersburg, indeed, indicate that the epidemic is dying out in that city, but in many of the provinces of Russia it is unabated, and others are being invaded. The Prussian frontier has been closed against Russia in all dangerous directions, but not much is to be anticipated from the old-fashioned methods in vogue.

What England has done to repel invasion is chronicled in the report of Dr. Thorne, which I have previously noticed. In that report it is shown that the inspection of our ports has been useful in stimulating the control of vessels arriving from infected ports. In 1892 this method was perfectly successful, save in the cases of thirty-five persons who landed during the period of incubation or when the disease had set in. Last year some cases occurred, as I reported to you at the time, in persons who passed inland, and we were face to face with the serious danger of an outbreak in several places at once. Now that that peril is past it is satisfactory to know that, besides the ports, these inland districts have been carefully watched, and, moreover, that inspection of other places exhibiting sanitary defects is being continued. The report contains some shocking examples of neglect and recklessness on the part of some local sanitary authorities, which deserve severe blame, and it is certainly to be hoped that the danger incurred will be brought home to all concerned. Dr. Thorne remarks that it is no part of his duty in such cases "to appraise the responsibility attaching respectively to electors or elected," and he evidently thinks that great blame is due to one, or probably both. It is, perhaps, a blot on our institutions that the densest ignorance does not disqualify an elector, or, for that matter, an elected person, and the representatives of ignorance are likely to be reckless administrators in sanitary matters. It is, indeed, a relief that the inspection of the Local Government Board is a reality, and that its medical department is presided over by so capable an officer as Dr. Thorne Thorne. The system of sanitary supervision he directs may claim success so far, but no doubt many details require perfecting, and it is to be hoped that the suspicious villages and towns will continue under observation as well as the ports which are specially exposed to danger. For we are not out of the wood even in regard to the present year, though some papers are already singing pæans at our escape; and not merely this year, but always and continuously, those precautions which have proved effectual must be maintained. Even those who still hold to quarantine have accorded us the approval of our methods which its success necessarily extorted.

MUST THE PARSON PAY?

To the Editor of the Medical Record.

Sir: With your permission I would like to ask Minister, whose letter appears in your issue of June 9th, a few questions.

Is it not a fact that laboring men and clerks who receive a salary of forty dollars per month (some less), pay their medical bills without a murmur?

Is it not also a fact that the vast majority of physicians do a great amount of work for which they receive not a penny, in some instances even furnishing the medicine?

Who has the harder and more responsible duty to perform—the minister who prepares his sermon during the week to recite on Sunday, and who visits the members of his flock on pleasant sunshiny days; or the doctor who has to answer calls at all hours of the day or night, no matter how tired and sleepy he may be, no matter how much snow, ice, or mud he may have to plod through, and who, when he reaches the bedside, instead of repeating a prayer which he has learned by heart, has to call into play all the resources of his medical knowledge, and upon whom devolves the responsibility of restoring the child to its mother, or the father to his family?

And last of all, what do ministers do to merit medical attention gratis? Truly I cannot understand it; and while I would never hesitate to answer a call of charity at any time, I fully concur with my friend of Durham, N. C., that when one is able to pay one should pay, whether he be minister, lawyer, or laborer.

Yours very truly,
C. H. Carroll.

Pavaris, Fla.

SOME PRACTICAL OBSERVATIONS ON MALARIA NOT DUE TO DRINKING WELL- OR SURFACE-WATER.

To the Editor of the Medical Record.

Sir: The article on malaria, by Dr. W. H. Daly, of Pittsburg, Pa., which appeared in the Medical Record of September 15th, was especially interesting to me, living in a malarial district (Twenty fourth Ward, New York City). According to his observations, malaria is due almost, if not exclusively, to drinking water contaminated by the germs to which the disease is attributed. That the mist, fog, etc., rising from marshy ground; the turning over of earth, incidental to filling in and raising the grade of roads, are incapable of causing the disease; and that no matter what may be the condition of the soil and drainage, providing we do not drink water containing the germs, we will not contract the disease.

While I agree with Dr. Daly that surface water and that from contaminated wells are one of the prime factors in causing the disease, I am compelled to differ with him as to their being the distinct cause.

If he be correct in his deductions, how can the following cases be accounted for?

Some two or three months ago, for the purpose of building sewers in my immediate neighborhood, the city authorities have been filling in and raising the grade of

one part of the road with earth obtained by lowering it at other points. This work had not been going on very long before I began receiving patients suffering from pronounced chills and fever. During the months of August and September (to date, the 22d inst., an unusually dry spell), I treated twenty-three cases of chills and fever, and nine cases with all the symptoms of malarial poison excepting the chill.

Now, let us see what influence well- or surface water had with their sickness. Close investigation resulted as follows: Of the 23 cases where all the symptoms existed, but 3 had drank water from wells, 2 from cisterns, and the remaining 18 from the regular supply furnished through the Croton Water Department pipes. Of the 9 cases where the chills were absent, only 1 case used well-water, and the balance used Croton.

Furthermore, some of my patients came from families consisting of from five to eight members, and in the majority of these cases they were the only members suffering from the disease, notwithstanding the fact that the entire family were using the same water-supply, and living, as far as I could ascertain, under identical circumstances.

Admitting Dr. Daly's water theory, how did the cases using the Croton water-supply contract the disease?

Admitting for the sake of argument that the Croton water-supply for this district may have been contaminated by malarial germs, how is it that the entire neighborhood is not suffering, as we all use the same water supply?

As to the drinking of contaminated water being one of the prime factors, I can offer proof positive in the person of myself. Some eight years ago, the house in which I then resided had for its water-supply a cistern and a well. After using this well-water for drinking purposes for a few months, I suffered from a very severe attack of chills and fever. Upon investigation I found the well was receiving the leakage from an out house as well as the surface drainage. Upon discontinuing its use all symptoms disappeared.

In conclusion, while admitting the water-supply to be a pronounced factor in causing malaria, it is not the distinct or exclusive cause. On the contrary, my observations point toward the mist, fog, etc., rising from swampy, marshy ground, stagnant water, decaying of rank vegetation, and the turning over of great quantities of fresh earth.

Further data upon this subject would be both interesting and instructive.

JOSEPH S. HEALEY, M.D.

KINGS BRIDGE, NEW YORK CITY, September 22, 1894.

IS BATHERS' CRAMP A POPULAR FALLACY?

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It was with great interest that I read the article entitled "Bathers' Cramp, is it a Popular Fallacy" in the MEDICAL RECORD of September 1st, and I should like to add my small contribution to the much that has been already said upon this subject. I have suffered from cramp not only in the cold waters north of Cape Cod, but also in the warmer waters south of it. Now the case quoted does not seem to me to be one of genuine cramp, for if the attack is severe it is quite impossible to move the members affected, even in a "dazed or mechanical way." I have had cramp at times in one and both legs, and in one or both ankles. When attacked in one leg it was in warm river water, and to get ashore was a comparatively easy matter. When attacked in both legs, it was in the warm waters of New Bedford Harbor (Mass) and it was with great difficulty that I reached shore by swimming on my back, both legs doubled up under me, and dragging myself up on the beach with my hands.

This attack was very painful, the muscles of the legs tightly contracted, violent pains in the head, and nausea. Slight relief was experienced on the instant of dragging the leg from the water, but the pain ceased only upon prolonged and vigorous massage. Cessation of local pain was followed by general debility, exhaustion, severe headaches, muscular fatigue, and slight nausea for two days.

I am absolutely certain that the liability to cramp is increased by tight garters worn either above or below the knee, tight shoes, or other obstructions to natural circulation. I have investigated several other cases, have dragged one person so affected out of the water, and in all there is a tendency to double up the legs, drop the head forward and bend the arms (as in the attitude of writing)—most favorable conditions to a death by drowning. I believe the tight garter to be the cause of many such deaths and would most strongly caution all those who swim or bathe, against it. Hoping that these brief observations and remedies, which have certainly been efficient in several cases of which I have had the treatment, may be of interest and assistance to many others.

W. LOUIS CHAPMAN.

LYNN, MASS.

PERMANGANATE OF POTASSIUM IN OPIUM POISONING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Although it is not a pleasant task to harshly criticise a confrère, yet I do not see how I could refrain from applying the epithet illogical to the report by Dr. McGuire of a case of morphine poisoning published in the MEDICAL RECORD of September 15, 1894. According to Dr. McGuire's statement, he came near losing his patient by "relying" on potassium permanganate. A brief analysis of the doctor's report will show the astonishing unreasonableness of this statement. One hour after the patient had ingested the morphine, Dr. McGuire began extending to him his medical aid. The following three hours he spent in resorting to the usual methods in vogue in the treatment of opium poisoning, not omitting of course large doses of sulphate of atropine, and incidentally giving 3ss. of the fluid extract of ipecac, which the doctor naively observes did its work fairly well in an hour and a half. After the lapse of three hours, or in other words, four hours after the morphine had been taken, Dr. Earnest arrived on the *champ de bataille* with a one-pound bottle of potassium permanganate, out of which quantity the patient received three or four grains *per os*. Twenty minutes later the patient sank into a deep coma, and it was only with the greatest difficulty that he could be roused again.

This is the *résumé* of Dr. McGuire's report. The reader will probably agree with me as to the peculiarity of the doctor's claim "to have relied upon potassium permanganate." I wish he had done so, for the timely and judicious employ of the remarkable salt of permanganic acid would have saved him a great deal of trouble and anxiety. In the first place, it would be impossible for anyone reviewing the doctor's report to know whether the three or four grains of the antidote were sufficient, even if they had been administered immediately, as we have no report of the amount of morphine taken. Second: In my original article on the subject,[1] I suggested the immediate use of from ten to fifteen grains of the antidote well diluted, irrespective of the quantity of morphine taken; and by what peculiar ratiocination the doctor could have concluded that by administering three or four grains four hours later he was following my method, I am unable to understand. As an analogue, if the doctor should prescribe a drachm of any medicine to be taken at a certain time, and his patient takes five minims three hours later, would the failure of the treatment reflect at all upon the doctor's method? Now, Dr. McGuire followed my method to the extent of using the antidote, but as regards time and quantity he was wofully injudicious. As to the deep coma supervening twenty minutes after the administration of $Mn_2K_2O_8$, it is out of the question that the permanganate could have caused this. I have yet to find any therapeutist who would impute narcotic qualities to it. This coma was only a relapse which, as the doctor is probably

[1] MEDICAL RECORD, February 17, 1894.

aware, is not an unusual feature of opium poisoning. However, it may have been aggravated in this particular case by the large doses of sulphate of atropine which the patient had injected into him.

WILLIAM MOOR, M.D.

355 BOULEVARD, NEW YORK, September 28, 1894.

LEPROSY IN INDIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: On p. 699 of the MEDICAL RECORD for June 2, 1894, in the review of the paper by Dr. White on the subject of "Leprosy," it is stated that there are in India two hundred and fifty lepers to day. This is very far from the truth, as the number given by the census of 1891 makes the number 119,044, and this is not quite complete, as it is rather above this number than under.

In an asylum alone, not far from here, there are over two hundred. In the asylum I have charge of there are one hundred. Besides these two asylums, in the Punjab alone there are over a dozen other asylums and places where lepers voluntarily have congregated. Some of these are under government or other control, while others are simply places which the lepers make a stopping-place, from which to go out daily, or for a few days at a time, begging for their support.

I am sending you by this mail reports of this asylum for 1892 and 1893.

Yours very truly,
Th. B. CARLETON, M.D.,
Superintendent Leper Asylum.

SABATHU, PUNJAB, NORTH INDIA.

TABLET TRITURATES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: If space permits, will you allow me to point out a matter that needs some correction. I think it will be acknowledged that tablet triturates have come to stay, at least for many years to come, they are certainly a "convenient and elegant" method of medication, but as prepared at present I think they are, at times, far from being "safe and accurate" as the manufacturers claim.

I have carefully examined samples from several different manufacturers in various States and find the same objection to all, namely that the ingredients are not triturated but simply mixed. This might do very well where the medicines are of a harmless nature, although by no means commendable, but when tablets containing arsenic, strychnine and the like are so carelessly made that you can dig out the various combinations with a sharp-pointed knife under the naked eye, I think it is time to cry halt. I verily believe that I have seen evil effects from several such tablets, and if I know of any better make I should leave all the others alone, but, as I said before, I find them all alike.

In my humble opinion all mixtures ought to be ground and triturated so that the finished tablet should exhibit one uniform color throughout the whole, and that the individual drugs should not be distinguishable even under a moderate magnifying glass. Only such can be safe.

"COUNTRY DOCTOR."

EAST EDDINGTON, ME., September 10, 1894.

A New Salt in an Ammoniacal Urine.—Cases of persistent and marked alkalinity of the urine, due to long administration of much lime-water, will be found on examination to be instances of ammoniacal urine due to the presence of a salt of carbamic acid. If, however, the lime-water is given in large quantities and continuously, it will lower the total output of ammonia as markedly as do the carbonates of the fixed alkalies, though then lime-water causes the appearance of free ammonia, which sodium carbonate does not do.—ABEL.

Medical Items.

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 6, 1894.

	Cases.	Deaths.
Tuberculosis	129	84
Typhoid fever	25	17
Scarlet fever	24	4
Cerebro-spinal meningitis	0	2
Measles	18	4
Diphtheria	112	21
Small-pox	9	1

The Typhoid Spine.—It is very probable that several distinct sequelæ of typhoid fever have been called "The Typhoid Spine." Four cases of neurosis following enteric fever are described by Dr. William Osler in the fourth volume of the Johns Hopkins Hospital Reports. In defence of the neurosis theory he states that joint and periosteal troubles are by no means rare sequences of typhoid fever, but that such symptoms do not usually develop after convalescence has been for some time well established, and that the periostitis, which is seen more frequently about the sternum and ribs, proceeds as a rule to suppuration. Periosteal swellings may disappear without suppuration, though periosteal thickenings protracted through weeks and months usually develop abscesses. Yet it is difficult to conceive of attacks of pain, lasting for months, due to a simple perispondylitis, which in none of the four cases passed on to suppuration. Though neurasthenia may not be the cause of all cases of "The Typhoid Spine," these four patients gave Dr. Osler that general impression, and it seems to him as probable that many of the cases are simply examples of the painful neurosis known as "spinal irritation," and analogous to the painful condition met with in the "hysterical spine," in both of which the patients may have pains on the slightest movements of the back or of the legs. In one of the cases the rapid recovery in a few days, with the disappearance of all the symptoms, was quite inconsistent with a chronic perispondylitis. In the four cases of this sequela of enteric fever, described by Dr. Gibney, of New York, as "The Typhoid Spine," there was the production of pain on the slightest movement, whether lateral or forward, and the absence of any marked febrile disturbance or neuralgia. All the painful backs after typhoid fever may not be neurotic, however, as there is a possibility of the existence of perispondylitis in some cases.

The Spirit of Quackery within the Pale of the Profession.—In an address delivered at the annual meeting of the Midland Branch by Dr. J. West Walker, the author, after referring to the characteristics of quackery in its barest and most uncompromising forms, proceeded to inquire whether or no the enemy—quackery—had gained an entrance within the profession. He animadverted upon the tendency on the part of certain dealers to advertise proprietary preparations with an amount of elaboration which appeared to him to be quite uncalled for (*The British Medical Journal*). He then turned to the attitude of consultants with regard to treatment, taking occasion in the first place to pay a high compliment to the diagnostic skill commonly exhibited, and frankly admitting that assistance in treatment was often obtained from them. But, he added, when I send to a consultant I invariably ask myself what novelty shall I have to procure, and this, notwithstanding it is the rule to have my surgery well supplied with most of the established therapeutic agents. The recently born mineral water or proprietary dietetic, the endless variety of the carbon derivatives with their break-jaw names, the latest importation from America, some form, of course, of antiseptic, the newest tabloid, capsule, or cachet, or some

drug, it may be, not to be found in the Pharmacopœia nor the usual trade lists, but only to be obtained from a particular chemist; these and such like form a tempting catalogue of choice novelties from which selection may be made according to fancy. I make it a point of honor scrupulously to carry out the consultant's plan of treatment, but if the case be chronic, say of cardiac or renal mischief, I soon find that one by one these addenda are dropped and that the general management of the case falls back upon the original adviser. He has to bring into play all the skill and judgment he may be possessed of to meet the various and varying symptoms as they arise, aided and supported by the line of right principle which he has received from his professional brother. But more, our patients usually return to us loaded with minute instructions as to diet and regimen.

Unfortunately, especially in the matter of diet, these instructions are by no means uniform. Different advisers give different advice. *Quot homines tot sententiæ.* The old adage that "what is one man's meat is another man's poison" seems to be completely lost sight of, and anyone whose inclination prompts him to do it can easily ride his hobby to death among the intricate bypaths of dietary tables. Exact details, both as to quantity and quality of the fish, of the flesh, of the vegetable which only are to be allowed; nice distinctions as to what beverages may be swallowed; careful directions as to the time for the infusion of tea; explicit rules as to meals, exercise, and habits generally; these and similar minutiæ are laid down and enjoined with great exactitude. If the patient can be induced to have faith in this dogmatism and obey it, if he adhere strictly to the diet and regimen laid down for him, if he become afraid of the taunts of kind friends on the least infringement of the doctor's orders, benefit to health will generally follow. If the patient who is in the habit of dining off half a dozen courses and of making his other meals proportionate, who freely partakes of beer, wine in variety, and whiskey-and soda—if such a patient can be induced to forsake his gustful yet disgusting diet and daily to take instead four pints of hot water and sundry messes of minced beef, it is easy to see that good will be done by the change, at any rate, for a time. And since the end is usually greater than the means, and since the end of professional effort must ever be the patient's good, something may be said in favor of means which conduce to such a desirable end, even though they be a wee bit irregular. May it not be well, however, to ask ourselves and fully realize the answer to the question, How far are these good results the positive effects of what we cause our patient to do, and how far the negative effects of what we cause him not to do? The removal of some vicious habit, some worrying occupation, or some unhealthy environment may really be the cause of good, and our remedies only contribute to bring about the result by the oblique rather than by the direct method. As before hinted, the oblique method may have something to commend it, and the practice of it may even, like homicide, be, under some circumstances, justifiable. Let not our eyes be dusty. If we strip this line of practice of adornment, and look upon it in its nakedness, we in too many instances recognize so many of the family features that if we would call a spade a spade we can designate it by none other than the family name. It may be that stratagem in medicine, as in war, must still be occasionally resorted to; be ours the care lest we award to the victory won by it glory in amount equal to that which we bestow upon the result of a hand-to hand encounter.

Returning again to the subject of new remedies, Dr. Walker observed that a new drug which was really useful required little advertisement. Of this the history of the introduction of chloral and cocaine was sufficient proof. He protested against the abuse, not the use, of advertisement; while condemning credulity, he would not favor its opposite—a dogged scepticism, which in an inexact science, such as medicine, was perhaps even more harmful than credulity. In conclusion, he uttered a note of warning as to the practice of prescribing mixtures in strong form, to be taken in doses of one or two drachms or of so many minims. To prescribe concentrated mixtures of strychnine, of arsenic, or of mercuric perchloride, and direct them to be given in various degrees of dilution was, he considered, a custom fraught with danger. To place side by side on the nurse's table, often in a dimly lighted room, two bottles of equal size —the one containing sulphate of magnesia to be given in doses of two tablespoonfuls, the other containing chloral to be given in doses of one teaspoonful—was a risky procedure, and one which, were the directions never so explicit, paved the way for that terrible catastrophe—poisoning by misadventure.

Treatment of the Milk Teeth.—According to *The Lancet*, Mr. Edmund Owen read a short but interesting paper on this subject at a meeting of the Odontological Society. He asked the question whether it was always the best plan to stop decayed milk teeth, and whether it was really an advance in treatment. He thought that in some other branches of surgery many so called improvements had in fact put back the dial of surgery, and that dentists were carrying conservative treatment too far, hesitating to extract from fear that the due development of the jaws would be interfered with, or that the second teeth would have to scramble for position after premature loss of the temporary teeth; but in his opinion the development was due to the presence of the tooth-sacs contained in the substance of the bone, and, with regard to the crowding, should it take place, it could be easily remedied by careful watching and weeding out if necessary. He said: "There is one point in connection with the dental surgery of children's teeth which I am sure has not received the attention which it so urgently demands—it is that children's mouths should undergo regular periodical inspection." Mr. Owen laid especial stress upon the removal of carious teeth where there was enlargement of a lymphatic gland in the neck, which, he said, so many dentists refused to do, probably foreseeing some possible contingency in connection with the eruption of the permanent teeth. Where the pulp of a tooth was exposed it was an extremely painful and difficult thing to do to clear out each fang thoroughly, and unless this were done it was merely "rolling a stone over a whited sepulchre," and further trouble was inevitable. The very germ with which the dental surgeon temporized in the alveolar region was often subsequently encountered in a submaxillary glandular abscess, but Mr. Owen thoroughly agreed with stopping milk teeth where the carious cavities were small or could be rendered absolutely aseptic.

A Statue to Thomas Sydenham was unveiled by the Marquis of Salisbury at the recent meeting of the British Association for the Advancement of Science, at Oxford. The presentation was made by Sir Henry Acland, Regius Professor of Medicine to the University.

Mineral Matter in Teeth and Bones.—The framework of the bones and teeth contains lime, phosphoric acid, magnesia, potash, soda, carbonic anhydride, water, chlorine, and fluorine. The water of crystallization passes off at a very high temperature, but the constituent water can be separated only by fusion with silicic acid.—GABRIEL.

Tobacco and Fatigue.—Moderate smoking, in one accustomed to tobacco, neither increases the amount of work done, nor retards the approach of fatigue. On the contrary, it perhaps slightly diminishes muscular power, and hastens the onset of fatigue, though these positive effects could not be conclusively demonstrated.—HARLEY.

The Future of Children with Hip-disease.—According to Bruns, six per cent. of patients under ten years of age, who have been cured of hip disease, nine per cent. of those between ten and twenty years, and seven per cent. of those above twenty years of age, succumb eventually to tuberculosis of other organs.

CONSUMPTION: ROUGHING IT VS. THE COD-DLING TREATMENT.

BY CHARLES E. PAGE, M.D.,

BOSTON, MASS.

"CONSUMPTION" is the same *bête noire* to-day that it has ever been. It is everywhere regarded as incurable, once fastened upon its victim. And yet, the records of the dissecting room prove that in numerous cases lungs, "wasted to one-half of their normal size have been healed, and after a perfect cicatrization of the tuberculous ulcers have for years performed all the essential functions of the sound organ" (Oswald). This fact, with all its great significance, should be impressed upon the mind of every medical student. It is doubtless true that in every instance, of all who live to tell the tale of an inherited or acquired tendency to pulmonary emphysema and of its banishment, we would find a history of either an enforced or a voluntary change from an in door to an outdoor life, with some radical modification of the living habits of the individual, especially in the matter of his activities.

The writer recalls the case of a cousin who was killed in California by being rolled down a mountain's side under a drive of logs. Possibly the first log that rolled over him did the business, but it was said by his companions at the time that nothing short of that sort of treatment could ever have killed this giant of 6 feet 3 inches, weighing 220 pounds, and noted for his muscular strength. And yet, throughout his boyhood and to the age of fifteen, he was about the poorest specimen of humanity imaginable. No one believed that this cadaverous, yellow-white faced, round-shouldered, hollow chested lad, with a "grave yard cough," would live to reach maturity, least of all become a robust man. No news concerning my cousin's condition reached me during an absence from home of about two years, and one may imagine my amazement when at our first meeting I looked up at the face of a six-foot athlete claiming to be the cousin whom I left in so sad a plight.

What had wrought this seeming miracle? Simply an enforced change from the life of a molly coddle to that of a worker in the open air. My uncle was the ferryman at N., a little village on the Kennebec, in Maine, and owing to an illness his only son was compelled to take up the work, which, though desultory, required the putting forth of all the muscular power to which he could whip himself, and exposure to all manner of rough weather. Instead of dying outright, as his poor parents feared, it was soon evident that his new life agreed with him; he began to mend, and it was doubtless owing to his father's prolonged sickness that the boy got his start toward robust health.

Instances more or less similar to the one just related are constantly occurring, but their true lesson is appreciated only by the few. Into another consumptive's head there came in some way the crankish notion of beginning the practice in summer of taking a cold plunge and swim in the neighboring pond and of continuing it throughout the year, breaking the ice in winter for his morning bath. Result: A perfect cure.

Another case that came under my notice was that of a young man who had as a clerk in a store fallen into decline and was forced to resign his position. He consulted me and was for a time under my care. He had at first no appetite, little strength, an emaciated body, and a distressing cough. He begun to improve somewhat, but was greatly disturbed by his enforced idleness, with all that this implied to a man with an ailing wife and child requiring support, and one day he informed me that a friend of his wanted a man to drive a milk wagon and would give him the job, and by my advice he accepted. Hustling out of bed at 1 A.M. first in the fall, and then throughout the winter, for a long drive, often in bitter weather, regardless of rain or snow; to jump off and on the cart in the delivery of his wares, gave him a boom toward health that resulted finally in making him a robust man.

An acquaintance of mine, once wealthy, lost all of his property except a "consumptive" horse that he had been keeping "for the good he had done," and whose ill condition had resulted from high living and a sedentary life. His master finally started a little grocery business, and at the risk of arrest by the agent of the Society for the Prevention of Cruelty to Animals, he began delivering groceries with the "patient." After a time the poor creature began to show signs of picking up, and as business increased, the work, of course, became harder; but the more he did the more he could do, and within a year this hide bound victim of misplaced kindness was again the plump, smooth, handsome creature that first attracted his master's attention. At that time he was fat, and he looked fat now, but this appearance was due to a fully developed muscular system, the result of hard work and enough to eat, with the natural improvement in digestion and assimilation from plenty of exercise in the open air.

As an illustration of the benefits arising from chest exercise, we have the case of the consumptive who received a wound in the leg and had to employ crutches. Finding that their use seemed to relieve his cough, helped him in the matter of "raising," etc., he got in the way of hobbling about as much as his strength would permit, and this naturally meant more and more, until by the time he could use his legs with freedom he was on the road to high health, and he did become healthy.

A few years ago a prominent Connecticut physician died, and an autopsy was made with the expectation of viewing a "lung and a fraction," with which he had lived for thirty years, after a prominent Boston doctor, in consultation with the late Dr. Willard Parker, of New York, had declared that he could not live a year. He had then just graduated, and he took his case into his own hands, and began a system of roughing it, out in all weathers, eating freely of hearty food. for which he gained an appetite by a nip of brandy at dinner. He became a robust man, and died finally of chronic gastritis resulting from sticking to the brandy habit! His lungs were both sound, and the doctors' diagnosis was, therefore, absolutely wrong; but their prognosis would without a doubt have proved correct but for his right about face and the adoption of the bulldozing treatment, so to say.

The writer has long since adopted this principle in the treatment of "consumption," which he regards as a disease of dyspeptic starvation. In its final issue, in cases that terminate fatally. patients really die of fatty degeneration of the lungs, so far as the local lesion is concerned. There is utter lack of full. free exercise of the lungs; the easy going, loafing patient does not half breathe, from lack of such physical exercise as would

cause involuntary deep breathing; and as a consequence the lung tissues degenerate with fat, as is true also of the entire muscular system.

Something like a dozen years ago, at a meeting of the New Orleans Pathological Society, Dr. H. D. Schmidt, whose researches had been extended and minute, made an important microscopical demonstration for the purpose of disproving Professor Koch's so-called discovery as to the bacilli of tuberculosis. Professor Schmidt claimed to demonstrate that the "bacilli" were simply fatty crystals, but he at least succeeded in showing that the condition of the lungs was one of fatty degeneration. We know, however, that the diseased lungs do contain minute living organisms, but it is evident to my mind that the bacillus is simply a natural scavenger of the decaying tissue, and that its function is really life-conserving.

It has for years been my practice to treat consumptive patients on the plan indicated in the foregoing paragraphs; the roughing, toughening, hustling plan, varied according to the special needs of each individual, which occasions a demand for a generous amount of wholesome food, with appetite and digestion to correspond. The result is as satisfactory when the treatment is prescribed by an expert as when it is merely the outcome of accident, and I will venture to introduce here a couple of instances of radical cure.

B. H——, at present one of our noted American artists in Paris, came under my care in March, 1885, after a three years' decline in Paris and London, and a return to his native Philadelphia to die, as they all believed, under the care of the old family doctor. The latter ordered him to Colorado, as is still quite the usual custom in hopeless cases, to loaf away the remnant of his life. He returned, however, after a few months' stay, unimproved, and it was at this point of the case that he wrote to me the history of his condition and asked my advice. After a few weeks' correspondence H—— and his wife came to Boston, that the patient might be directly under my eye. He had, meantime, made a slight gain, and could do more rather than "crawl a mile on level going," as he described his physical powers in his first letter. He could manage a couple of miles without extreme fatigue, and from day to day I cracked the whip over his back, so to say, to secure something of a gain in speed and distance at each trial, as well as in the number of his daily walks, with ample rests between, chiefly lying down. He was a brave fellow and he entered into the plan with all the spirit he could muster. On rising from bed he was directed, as a daily practice, to take a quick dash of cold water all over, a good towelling, and an air-bath of a half-hour or more, with such all-around exercises as he could manage. After a few weeks he would, naked, pull at the chest-weights for an hour or more before breakfast, like a man sawing wood. Light, low-cut, loose shoes, only, were worn. He went barefoot several hours every day. Before the end of summer he could do fifteen miles in the course of the day, at several stretches, including a good bit of running, and was eating hungrily twice a day of good plain food. Three tonics only were exhibited: Fresh air, fasting, and exercise. My counsel to him was what it ever is to all classes of patients: Never eat unless hungry. To eat without appetite is a species of self-abuse inexcusable for the sick or well. Never eat when tired, nor exercise actively soon after eating. Learn to distinguish between hunger and mere appetite; let the test be the least appetizing foods; and if hungry enough to enjoy such, one may partake of the more agreeable kinds, as a steak or chop, a mellow ripe banana, new peas, corn, string-beans, all of the seasonable fruits, berries, melons, etc., but the consumptive, of all men, must avoid gormandizing.

In October, after seven months' physical training, H—— and his wife returned to France, and within a year thereafter he was enabled to report himself "as sound as a dollar." I have heard from him every year, and he remains still a typically healthy man.

R. T. S——, aged twenty-three, a most unpromising subject, weighing on my scales 99 pounds, came to this town to be under my care, in February, 1887. His appearance was so pitiful as to almost excite disgust. His weakness was so extreme that his brain was seriously affected. But he seemed in dead earnest to get my ideas on every point to carry them out to the letter. He kept most of the time in the open air, regardless of the weather, worked up gradually in his training, indoors and out, but he grew restive from having nothing to do but attend to himself. He finally conceived the notion of canvassing from house to house for orders for provisions as a means of keeping himself out of doors and his mind occupied with something beside his own symptoms. His success was largely due to the pity excited by his forlorn appearance. He would get his orders, and then visit the large markets and buy the meats and provisions to fill them. He was therefore a merchant and had the stimulus of looking for profits. All this work was on foot in all weathers during March, and continuously thereafter, and he began to gain in weight and strength. In May he weighed 110 pounds, and the following year he tipped the beam at 145, and was a bright, handsome fellow.

In both these cases the patients at once, by my direction, abandoned the use of the heavy flannels they were wearing when they consulted me, though they were, of course, well protected from the cold when out of doors by means of outer garments. The disuse of under-flannels as an important part of hygienic treatment will doubtless fail to commend itself to most of my readers; but in a very busy practice during the past ten years I have invariably urged the plan upon my consultants, and I have succeeded in a large number of instances in inducing them to abandon the use of underwear altogether, not even compromising with light-weight, and I have never had occasion to regret it; but, on the other hand, I have won the gratitude of every individual who has given the plan a fair trial.

Is it not clear to every reflective mind that in all ordinary homes we and our patients are living in summer weather, so to say, even in mid-winter? Why, then, should we wear winter flannels in the house? The employment of outer garments for out-door wear meets all the requirements for comfort, and all the better when the skin is not sweltered by flannels in the heated, often over-heated, living-rooms; and I have observed as an invariable rule that those who have adopted the plan here advised are the most indifferent as to the use of outer garments when they do go out, even in winter. It is the ones who swelter the skin with heavy flannels in their warm dwellings, offices, stores, etc., who shiver most in cold weather in spite of the heaviest sealskin sacques or fur-lined top coats.

The writer has worn no flannels, winter nor summer, since February, 1880, removing during this winter month, the heaviest of Morley's Scotch undershirts and drawers. For years he had, in his efforts after comfort, selected his winter flannels from garments of heavier weight each fall; but all to no purpose, except, seemingly, to make him subject to a kind of chills and fever, very sensitive to cold when out of doors, and exceedingly uncomfortable indoors at all times, and also out doors in moderate weather. He was subject to frequent "colds" affecting throat and lungs, and a constant sufferer from cold feet, and in fact was in a condition to slide into a consumptive's grave, as had quite a number of his near relatives who died in their flannels! But now, at the age of fifty four, he is one of the most robust of men, able to lead most of the young men in a cross country run, not limiting the distance. And this change was produced by the abandonment of the coddling plan, replacing it with a rational application of the rough-and-tumble scheme outlined in this paper.

"It is not always realized that the ability of man to carry his climate with him, or essentially modify it wherever he chances to be located, is a power that can be

used for harm as well as benefit," says the *Philadelphia Polyclinic*, editorially. "When we depart from the guidance of the immediate sensations and race instincts, and shape our conduct according to definite ideas, we accept a guide that may be better or worse than those of nature; and, in the matter of clothing, there can be no question but that incorrect ideas lead many into the very disease and danger that they are striving to avoid.

"All observation shows that for individuals in comparative health, no possible regulation of environment, either in the selection of a natural climate, in the construction and heating of dwellings, or the choice of material and amount of clothing, can supersede, or, indeed, compare in importance with the influence of the physiological mechanism for the regulation of heat production and heat distribution, within the body.

"To keep this in the most perfect working order should be the first concern of one who fears disease from change of temperature; and it cannot be kept in good condition without opportunity for constant and considerable exercise. The natural stimuli which provoke its action, and which are essentially variations of heat and cold, particularly properly proportioned shocks of cold to the surface of the body, must be supplied or permitted, and on the other hand, the nervous system, of which it is an integral part, must be kept in good order by the proper balance of physical and mental exercise and sleep. Probably the persons who suffer most from 'colds' are those who, in their fear of such departures from health, try hardest to avoid the changes of temperature that are necessary to keep the heat-regulating organism in good condition."

The person who, on rising from bed in the morning, takes an air bath (as everyone should) in his unwarmed, winter sleeping room, for ten to thirty minutes, with a good towelling and hand polishing of the skin, prefaced, perhaps, by a dash of cold water with the wet hands, finding himself finally quite warm though naked, is in a position to conclude that the single, ordinary suit, minus flannels, will sufficiently "protect" him from cold when he descends to the warmer living-rooms! His overcoat and a brisk pace will do the business for him when he seeks the actual winter weather without, and this vastly better because of the freedom of the skin indoors.

Chilliness, or that more or less vague, shivery feeling that comes especially to all clothed animals, is apt to mislead the inexpert. Who has not experienced it in the evening, perhaps before a warm grate, temperature in the room at 70° F. or over, the body clad in full winter costume, and, on disrobing for bed in a cold room found himself comfortably warm? This seeming miracle would happen to every shivering mortal if he would give the skin a few active passes with his hands or a towel, instead of dodging from his clothes into bed in cowardly fear of "catching cold."

A leading question with me in every consultation, as a means of ascertaining how bad the condition is throughout the year, is, "Do you catch cold easily?" In the great majority of cases the reply is in the affirmative. "Yes, I am seldom free from a cold," one will say; or, "I catch cold if I even look out of the window." "I don't know whether it will take more than one of the air-baths you have prescribed to kill my wife," wrote a correspondent, "for she usually gets a cold if a fly wings past her; still, live or die, she says she is going to obey instructions." She began abruptly to take the air baths, gave up flannels, and within six months this 91½ pound woman was tramping barefoot three miles at a stretch in the surf along the beach, and had gained a few pounds of honest muscle, and was no longer a victim of the colds delusion. Symptoms of ill condition she would from time to time observe, due to some error in living habits, but she has learned to call things by their right names, at least some things.

Now and then a patient is able to declare that she seldom has a cold; and it always happens that she is one of the few not given to the practice of bundling herself up as a means of avoiding the disorder.

"How is it that I always catch cold when I put on my winter flannels?" queried a patient, who was upon the point of making his usual fall change of underwear. My explanation was so convincing to him that instead of putting on his thick flannels he took off his thin ones, and in the spring he was able to declare that he had never, since his unflannelled boyhood, passed a winter with such immunity from the popular disorder, "colds." He had, moreover, he said, enjoyed a greater average of comfort than formerly with the inner suit.

An elderly lady, herself a victim of heavy flannels and a "chest-protector," and who died, finally, from her fourth siege of pneumonia, once remarked to me in the presence of a little company at her hotel, that "there might be a great deal in your theory about the mischief of underwear, after all. Sam [referring to her husband by his given-name] never wore flannels till the last winter of his life. I had coaxed him to every fall, but he would not give up till one fall he let me get him some nice warm flannels. He seemed to have a cold all winter long, and he died of pneumonia in the spring." "Well," I replied, "you may have the sublime satisfaction of knowing that you were responsible for Sam's premature death!" Twenty years having elapsed since her investment in men's underwear, she was able to join in the laugh that was raised by my somewhat brutal remark.

The conviction has grown upon me from many years of special study of the question, that a "cold" is really a filth disease, and that, as that wisest of men, Dr. Benjamin Franklin, wrote,[1] "the causes of colds are totally independent of wet or even of cold." If this is not true, how can we account for the efficacy of the barefoot cure in certain disorders? When an empress suffering from neuralgia to the point of distraction finds complete cure from going barefoot for several hours every day in the wet grass about the palace grounds; when Baron Rothschild goes to Woreshofen and is pleased to pay a large (voluntary) fee for similar treatment, under Kneipp; when Dorothy Drew, the granddaughter of the "Grand Old Man" of England, becomes "irrepressibly healthy," from "going barefoot all the year around, indoors and out, in all but very muddy and the very coldest of weather," is it not about time for us to revise the old-time notions as to what constitutes really wise care in the matter of clothing?

The skin is a breathing, as well as an excreting organ, and both these functions are seriously impeded by the second, or inner suit. Indeed, the employment of any clothing at all, at times when not absolutely required for protection against cold, is a tax upon the animal organism, and against us in the search for health. This is doubtless especially true concerning the care of the feet. "Strip off your flannels, and you'll come out all right," was the advice for which an uncle of mine, in Australia in 1853, paid a guinea, and which he afterward had reason to believe would have been cheap at ten times the cost; for by obeying the level-headed old native doctor's advice he escaped the "climatic fever" which cost my brother his life there shortly after. The latter could not divest his mind of the superstition, still prevalent, that it is dangerous to keep comfortable in hot weather!

But how about our consumptive patient, shall he not be allowed to dress comfortably in winter? Comfortably, yes, by all means; but it is the greatest average of comfort we have to secure. If he is to pass all of his time in the open air, in winter, he may dress accordingly, even to the use of underwear; but as the average patient does nothing of the sort he will be better off without it. He will have chilly sensations at times whether he does or does not wear flannels, but it is vastly better for him, as for us all, to secure a feeling of warmth by means of a little "shaking up" exercise, than to try to secure comfort solely by means of excessive

[1] See his Essays, p. 216.

clothing. It is astonishing to one unfamiliar with the experiment to observe the almost instantaneous glow of warmth that results from a little arm-swinging, a few sharp slaps along the sides of the legs, a bit of a jig-dance, or even a few simple shrugs of the shoulders alone; and every little turn of this sort is in the line of physical training, from lack of which, in ninety nine cases in the hundred, our patient has fallen into decline. Generally speaking, the consumptive is one who has grown weaker and weaker, and, however slender he may have become, relatively fatter from month to month, the muscular system having steadily degenerated, because he has exerted himself less and less, being forever encouraged in this course through the mistaken kindness of all about him. He has, therefore, finally become "tired" in a manner prohibiting all hope of rest this side of the grave, except it be sought along radically changed lines.

Says Dr. Felix Oswald:[1] "A common catarrh will not prevent a man from running upstairs or walking uphill for minutes together without anything like visible distress; subjected to the same test, a person whose lungs are studded with tubercles will pant like a swimmer after a long dive, and his heart beats will most likely be doubled in frequency. Combined with a hectic flush, night-sweats, or general emaciation, shortness of breath leaves no doubt that the person thus affected is in the first stage of pulmonary consumption. If the patient were my son, I should remove the windows of his bedroom, and make him pass his days in the open air—as a cow boy or berry-gatherer, if he could do no better. In case the disease had reached its deliquium period, the stage of violent bowel complaints, dropsical swellings, and utter prostration, it would be better to let the sufferer die in peace; but, as long as he were able to digest a frugal meal and walk two miles on level ground, I should begin the out-door cure at any time of year, and stake my life on the result. I should provide him with clothing enough to defy the vicissitudes of the seasons, and keep him out doors in all kinds of weather—walking, riding, or sitting, he would be safe: the fresh air would prevent the progress of the disease; but improve he could not without exercise. Increased exercise is the price of increased vigor. Running and walking steel the leg sinews; almost any bodily exercise—but especially arm swinging, wood-chopping, carrying weights, and walking up hill—increases the action of the lungs, and thus gradually their functional vigor. The problem is to make out door exercise pleasant enough to be permanently preferable to the *far niente* whose sweets seem especially tempting to consumptives. This purpose accomplished, the steady progress of convalescence is generally insured, for differences of climate, altitude, of age and previous habits, almost disappear before the advantages of an habitual out door life over the healthiest indoor occupations."

But, when he comes in doors it must not be to find a close atmosphere, such as at present the average home provides; for, as Dr. Pitcher remarks in his "Memoirs of the Osage Indians," "the symptoms of consumption (caused by smoking and confinement in winter quarters) disappear during their annual buffalo-hunt, but reappear upon their return to the indolent life of the wigwam." And even an hour or two in the average theatre, church edifice, hall, or dwelling will counteract the benefit arising from spending an equal length of time in the free open air. In this fight for his life no patient can afford to hazard his chances by any letting up in the "medicine." At best, life is a struggle; courage is demanded; and in no phase is this more absolutely true than in the consumptive patient's endeavor to secure a return of health.

"You'd hardly think to look at me, I guess, that I'd been turned out to die of consumption before I came of age," said a 200-pound man of good muscle, a sturdy eater and sleeper, to a New York *Sun* reporter. "It's a fact, though. I weighed 95 pounds when I left home. My folks were poor, and they sent me to Kansas in a prairie schooner, never expecting to see me again. I began to pick up as soon as I got up on the rise of the plains. I lived in a cabin that was wide open day and night. Then I went into the army during the war, and after that did a lot of work grading and surveying for a railroad, and all the time I was living and sleeping with only the sky for a roof. I have been farming it for the last dozen years, and my windows are open day and night. Air is the best medicine there is."

It is for a profusion of this medicine that people go camping out. The consumptive patient must camp out all the year around, as does the writer and his entire family, practically. All one has to do is, in summer, to run the curtains up, burn the smothering screens, open wide the windows, top and bottom, and let the breezes blow freely through the house; in winter some degree of modification of this free ventilation is admissible. This means a lot of dust in summer, of course, and the fading of the rugs and furnishings, but it keeps the color in the cheeks, this "camping out at home."

"Beware of draughts," is the great cry of most writers on health. In other words shun the running stream, drink from a stagnant pool. "The only trouble about a draught," says Oswald, "is that it is usually not big enough!" And rationally considered this means nothing out of line of true hygiene. It does not mean that even a well man should sit passively in a strong current of cold air when he is fatigued or weakened from any cause.

It does mean, however, that no dwelling, no sick-room, can be sufficiently ventilated without a sufficient current. For winter ventilation, probably no better method can be devised—for the extremely cold weather—than to mismatch a number of windows in each room by means of a four inch board under the lower sash, which allows, through the middle opening, and without "draught," pretty free influx of fresh, and the passage out of foul, air. Open grates are without doubt an excellent thing, but it should be borne in mind that they let in no fresh air. The open windows must do this; and in the warm periods of mid-winter they should be freely opened throughout the house.

The consumptive patient on coming in from his outings may well seek his chamber with its always wide-open windows, and lie down with plenty of blankets for protection, instead of sitting, as a rule. Sitting is altogether unnatural, and the less of it he does the better. He may well avoid all unnatural practices until he finds himself safely "out of the woods."

867 Boylston Street.

[1] Physical Education.

The Temperature of the Electric Arc is said to be about 6,152° Fahrenheit.

Medical Valets.—Marcellin Pellet, in a work entitled "Naples Contemporaine," says that the valets of the leading physicians of that city always accompany their masters on their professional rounds, and receive two francs for each visit. They are paid no other salary, and out of those fees have to meet certain charges, such as that for lighting the house.—*Médecine Moderne.*

A Confinement that Didn't Confine.—A medical man who had practised among the North Dakota Indians, writes that their women as a rule had very easy labors; in fact, it was no trouble at all for them to have children. At one time he saw several women coming toward the only store at the agency, across a wide open space in front, each carrying on her back a bundle of sticks. Suddenly one stopped short, looked a little wild, dropped her bundle of sticks, spread her feet apart, strained a moment, and then stooping, made a pass toward the ground with her knife that she drew from its sheath, picked up something which she wrapped up in her shawl, and leaving her bundle of sticks for someone else to pick up, passed on into the village. That was a confinement, and the child was born then and there.—*New York Medical Times.*

ACUTE BILIARY DISTENTION OF THE GALL-BLADDER.

By BEVERLEY ROBINSON, M.D.,

CLINICAL PROFESSOR OF MEDICINE AT THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

It is always a subject of interest to clear up, if possible, some of the obscure conditions pertaining to cases not infrequently met with in general practice. Such an one, at least in certain of its essential features, is the state to which the title of my article refers. On two or more occasions, during the past few years, I have seen instances of the following kind: A patient is suddenly attacked with intense pain in the epigastric region. Accompanying the pain, which is continuous and remains, during the acute attack, limited to the epigastric region, there is constant nausea and occasional vomiting. The vomited matter is composed of the contents of the stomach, or is pure bile. There is no rise of temperature. There is marked local tenderness on palpation in the region to which pain is referred. Distention of the gall-bladder is not clearly made out, but it is suspected and probable, by reason of increased resistance and perhaps local swelling in its vicinity. The liver is usually somewhat enlarged. Constipation is moderate. The motions are dark brown, insufficient in quantity. The urine is high-colored, but does not contain any bile. It is possible to have a sub-icteric hue of the sclerotics, but there is no other evidence of jaundice. There may be a history of malaria, or lithæmia. The habits are occasionally regular; sometimes there are errors of diet or modes of life, as to exercise and excitement. During the attacks a vomitive with ipecac, a stimulating enema, with a hot-water bag applied locally over the stomach, will afford relief. Usually, however, this relief is only slight in amount, and the pain may last continually for several hours, and be so intense as to require the use of morphine hypodermically. For a day or two following these attacks, the epigastric region is tender. Fluid diet, relative quiet, counter-irritation over the liver, moderate catharsis with Rochelle salts, or carbonate and sulphate of magnesia, and the free use of Vichy water, will usually bring such attacks to a favorable termination in a short time. They recur at irregular intervals, usually after exposure, undue fatigue, emotional disturbance, some imprudence in eating or drinking. They are not followed by jaundice; no gall-stones are passed. They improve very much at first with free evacuation from the bowels of large, liquid, dark colored, bilious stools, which gradually become lighter in color as the individual improves in health. After such an attack the patient is usually well for several months, has no nausea, dyspepsia, epigastric soreness, engorgement of the liver, or as a rule, other evidence of ill health.

Occasionally, I have known sufferers from these attacks to have ambulant neuralgic pains, principally in the hypochondriac regions, but also in the thorax, abdomen, and testicles. Shooting pains in the testicles, with a feeling of weight and temporary swelling of the epididymis, have been observed. Such attacks have been designated gall-stones, acute dyspepsia, catarrhal jaundice, gastralgia. They are unlike all of these, and must be distinctly separated from them. When the abdominal pain is acute I have known appendicitis to be suspected. They are obviously different from this disease. The subsequent treatment of such cases, and between recurrent attacks, is to be found in continuous moderate doses for several weeks of phosphate of soda, sufficient in amount to produce a laxative effect on the bowels. An underlying malarial history has been clearly made out in more than one instance, and yet quinine is of very little value in these cases. Warburg's tincture may be helpful, but not infrequently only renders the condition of the patient worse. Arsenious acid, from $\frac{1}{60}$ to $\frac{1}{30}$ grain, combined with ignatia, has seemed to me to be the best and most rational curative treatment. After stopping the phosphate of soda, or instead of it, small doses every other night of podophyllin, or calomel, for a while have been found very useful. I direct attention to these cases, although not serious as to their immediate consequences in my experience, because they are often confounded with other affections, and because sooner or later, if not properly cared for, I am of the opinion that they lead directly to the formation and deposit of biliary calculi.

Two cases that I have observed and treated—one of them for many years—have occurred in young men between twenty and thirty years of age. Both of them lived an out-door life, were devoted to athletic sports, and generally speaking, were careful as to their diet. Similar, or analogous cases, occur more frequently among men than women. I have seen them occasionally in hospitals, but there they have been so much obscured by complicating disorders that I have not felt so confident in regard to my diagnosis. This diagnosis, which has only been a suspicion for some time, has now become a confirmed judgment in view of several more or less similar instances that I have taken care of. I am not aware that this precise affection has been emphasized or insisted upon by anyone else in quite the terms, nor in the manner, which I have tried to make clear. Engorgement, or congestion of the liver, does not fit such cases, as I believe, although slight enlargement usually accompanies the symptoms described. Besides, I have noted the other symptoms more than once, when there was no enlargement of the liver at all.

To my mind, these attacks of acute distention of the gall-bladder with bile, are not unlike, in their analogy with the development of calculous disease of the gall-bladder, to what we have similarly defined, when we consider the relationship of the pre-albuminuric stage of chronic Bright's disease with the development of nephritis as a clearly formed malady.

To give a plausible explanation of the etiology of these cases, I am almost forced to admit the existence of a spasmodic contraction of the gall-bladder which is sufficient to shut off in part temporary connection with the cystic duct. I cannot believe in the extension of an inflammatory condition from the duodenum, as there are none of the previous stomachal symptoms which are so usual in catarrhal jaundice. Moreover, the jaundice itself does not occur as it would, unquestionably, if the hepatic duct or common duct were occluded even for a short time. Again, it is more than difficult to admit the existence of an inflammatory state of the cystic duct which would allow the common or hepatic duct to remain intact or unaffected. Of course, the post-mortem revelations in similar instances cannot be given, as such cases are not fatal, and we are forcibly thrown back upon the explanation which is most rational, and therefore most satisfactory. Cases have been observed, or at least alluded to, by Murchison,[1] in which the organic occlusion of the neck of the gall-bladder by a gall stone was such as to allow entrance of bile into the gall bladder, but to prevent its exit. It is quite conceivable that a state may be produced after a dynamic manner, which might approximate this condition, *i e.*, that of a plug valve, "and where bile has in consequence accumulated in the gall-bladder."

It has occurred to me that cases like mine have occasionally been confounded with gastralgia, which, however, differs materially from what I have described. The latter disease is rarely so acute, is not accompanied by any swelling or hypertension over the region of the gall-bladder, is relieved frequently by pressure, or with bromides and chloral internally, and the attacks are not followed by copious and frequent bilious stools. In two of my cases, so soon as the spasmodic condition of the gall bladder was diminished, or suppressed, the symptoms of hepatic colic disappeared very rapidly and almost completely. In other somewhat analogous instances, they remained in a far less severe form for a few days. The evidence in these acute cases of biliary distention of the

[1] Diseases of the Liver, 3d edition, p. 381.

gall-bladder, is to the effect that the coloring matter of the retained bile is not gradually absorbed, but quickly eliminated by the bowels. Thus there is a radical difference with chronic cases of occlusion of the cystic duct from calculus, or any other cause where the contents of the gall bladder are an almost colorless mucous fluid. In either the acute or chronic cases of occlusion of the cystic duct, there need be no jaundice, nor clay colored motions. By directing attention to the foregoing facts I hope to throw some light on an interesting affection, which all general practitioners must occasionally see, but do not perhaps designate or interpret as I have done.

HYPOCHONDRIASIS.

By D. B. McCARTIE, M.D.,

NEWARK, N. J.

Historical Sketch.—Since the days of Hippocrates and Galen this nervous disease has been known and written on. Hippocrates wrote on hypochondriasis. The cerebral nature of the trouble did not enter into the medical nosology until much later. The ancient idea related to disturbance of the visceral organs situated under the ribs, as the name implies, and the gloom or depression accompanying the disease was ascribed as a result of deficient action in the liver connected with the production of bile, or in a perverted action in the spleen, whence the term "splenetic." This pathological idea was held through many centuries, and may have been popularly handed down by such treatises as Burton's "Anatomy of Melancholy."

In the days of Cullen the malady began to assume a new aspect and appear in its proper place as a cerebral affection.

The disease presents itself in so many various forms, or rather, its manifestations are so pronounced that these have been called by special names, and even worthy treatises have been written thereon. It is evident that all these phases, so much written on at the present day, are manifestations of the same disease; but one symptom standing out more prominently than others, the mental aspect of the case being unobserved, has received a special name, as "spinal neurasthenia," "cerebral or spinal hyperæmia," rachialgia, or spinal irritation, etc. Prominent authors have much differed about the nature and causes of these terms. Many have placed the seat of the trouble entirely in the cord. Griesinger places the malady *in toto* in the scale of insanity, observing minutely the depression, and instancing his observations by advanced hypochondriacal cases. Again, other authors place such signs as muscular asthenopia, motor weakness, cerebral sensations, sensory sensations in the skin, etc., in a separate class and call the trouble neurasthenia, leaving out the mental perversion, though suggesting that the malady occurs in hypochondriacal and hysterical patients.

Sir William Gull in his able article differs from Griesinger, and places the disease in a position midway between insanity and hereditary nervous disease, still retaining the indefinite name of hypochondriasis. He observes its close connection with insanity and its peculiar course, yet does not instance precisely phases of the malady which are often prominent, and in the main absorb all the other features of the disease, as ocular weakness, neurasthenia, sensory hyperæsthesia. Most authors seem to think that a delusion as to being diseased is the essential part of the disease, whereas this is often wanting in definiteness, and motor weakness, irritability of temper, want of sleep, and want of power to direct the attention, or the so-called neurasthenic symptom, is often the leading symptom, without the patient fearing disease, though a mental "cloud" still hangs over the understanding. Dr. Gowers places the disease in its proper category, and observes on its various features, but does not combine its symptoms. In speaking of neurasthenia he simply refers to hysteria, neuralgia, hypochondriasis, as its causes. He might as well have written an article on hypochondriasis as on hysteria, and combined all these symptoms, which undoubtedly refer to this peculiar and frequent and much discussed disease. Dr. Gowers touches, in various parts of his treatise, on some of the features of the hypochondriacal malady, particularly in the article on cerebral hyperæmia, cephalic sensations, neuralgia, hysteria, railway shock, etc. These symptoms connected together form the varying picture of hypochondriasis.

It has, therefore, a mental aspect in all cases, and this is probably the underlying morbid feature of the malady, though it is often slight and unobserved, but again, often so prominent as to place the case in the melancholic variety of insanity. A better name than hypochondriasis is manifestly wanted, as also a due connection of all the symptoms with the mental defect, so that the cases can be treated scientifically and the nature and course of the disease mapped out. Unfortunately it is too plain that it is so closely allied to the higher types of mental perversion that its prognosis depends on uncertainty and its treatment is tedious and non specific.

Definition.—The above name is badly chosen, since it conveys an erroneous impression as to the seat of the disease. Neurasthenia, which is so often a leading feature, is also an indefinite name, since debility, referring particularly to the nervous system, is as much a symptom as debility from fever or general disease. The term indicates many obscure symptoms which result from nervous disease, and should be known as a symptom of cerebral affection and not as a disease in itself.

Ætiology.—This relates almost entirely to hereditary effects, which are mostly untraced and indefinite in the course of ages. A definite history of family insanity can be obtained in very many cases, or other mental peculiarities or eccentricities. In fact the definition of insanity as a perversion of the normal state of thinking, feeling, or acting, applies very concisely to this condition, though the perversion of thinking is often very slight and not much noticed by the sufferer; whereas in other cases the perversion of thought is highly accentuated and hypochondriacal fancies abound. There are frequently histories of epilepsy in other members of the family, as in an uncle or aunt, and other nerve disease, as neuralgia, hysteria, chorea, megrim, etc. The disease also occurs indirectly or in connection with other diseases, a primary instance being the effect of railway shock upon the mental action of one prone to this disease.

The disease often occurs in young adult life, the first symptoms being a slight dyspeptic attack or a trifling sensation over the stomach region, which the patient takes for dyspepsia. Ocular weakness often begins the disease, or peculiar sensations about the head or extremities. Spermatorrhœa also gives the patient a cause for complaint, when in reality the symptoms are due to the commencing cerebral affection. After this manner many slight and presumably local ailments are treated as if distinct, and indefinite names, as nerve exhaustion, spinal irritation, etc., are given to them.

The mental condition is unobserved, and these concurrent symptoms are found to be exceedingly intractable and obstinate of treatment.

Symptoms.—The term disease is very aptly filled in by this nerve derangement, since both mentally and physically the patient is without ease. The symptoms admit of no distinct delineation, since they vary in form, time, and course. A leading symptom is motor weakness, which has been mistaken as a special disease, since it often predominates and is necessarily much noticed by the patient. This symptom is also called nerve prostration or brain exhaustion, when generally the brain was not overtaxed. In fact this sign is often predominant in cases where no brain labor has occurred, and it is also unrecorded where, when, and how the nerve-tissue would give way under severe exertion.

Normally the brain acts without the cognizance of the body. In this mental affection the mind is painfully aware of its relation to the body, and feels its want of free

and healthy action. This morbid attention is a great source of annoyance to the sufferer, and, if free from this condition, the mere debility or neurasthenia would not be more wretched or prolonged than in any ordinary case of convalescence. The attention is also fixed on the sensory sensations or nerve currents passing through the body. From at first indefinite sensations in various parts a fixed attention occurs, causing uneasy sensations, foci of neuralgic pains, which are misconstrued into disease of organs situated near the painful spot. Even when these constant and annoying pains occupy the attention of the patient he is also aware of mental uneasiness. These pains are most common over the epigastric region, and around the lower ribs, on top of the head, in the mucous membranes, in the outer side of the limbs. They usually remain in the skin, though often the deep nerves are very painful to pressure. The motor nerves are also much affected. These normal nerve-currents are perverted in some way until great weakness results, flabbiness of muscle, and much want of power and endurance. The patient feels fearfully fatigued after trivial exertion. This is so often a very prominent symptom that it has received the name of neurasthenia; but it is sufficient to prove it but a symptom to remark that when the mind is easy and gay, or the patient's attention sufficiently diverted, that the sense of fatigue is forgotten; or again, the weakness is cured in a day, when the mental ailment of the patient is dissipated, and he feels like a new man. Belonging to the sensory phenomena are several lesser signs, as heat flashes in warm weather and cold thrills in winter; the hair often becomes rough and falls out, and even the skin chafes in places and becomes red. When the sensory sensations are not marked enough to cause neuralgia, the attention of the patient being called to them, according to his mental aspect, forms them into disease of the organs beneath. The mind being very diseased, hypochondriacal fancies arise, whereas if the patient is only depressed, the sensations act as a hyperæsthetic skin trouble, but none the less fix his attention and give rise to extreme annoyance. The loss of power he could tolerate, but the indefinite sensation is ever prominent and occupies his attention in spite of all his efforts.

The mental aspect of the case is probably more persistent than all the other symptoms, if it be not the cause of the entire nerve derangement. It would be difficult to say whether the mental perversion keeps up the morbid attention and brings about the motor weakness and sensory phenomena, or whether these disease the mind; but most likely they are effects of a morbid fancy, for almost all cases entertain erroneous ideas regarding their condition. If all neurasthenic cases were looked into, mental irritability, weakness, and evident mental distress would be found, though it were not developed into marked hypochondriasis, as it is in many cases. But since one set of symptoms, as the painful neuralgic feelings, are intensified at one time, and the mental ill or cloud at another, it is likely they are parts of the same brain change. They do not form a distinct chain of events, as in migraine, though frequently there are distinct remissions and intervals of improvement, the morbid condition lasting much longer than the interval of quiet.

The disease brings with it a long train of varying symptoms in the sensory, motor, and mental systems of the brain, and probably affects its entire mechanism rather than that the mental perversion should cause the concurrent symptoms. The obscurer centres of the brain are also affected—the heart often beats slowly and wants force and tension. The respiration often appears to the patient as if about to stop, and is painfully felt. The sympathetic system suffers, various vaso motor flushes and perspirations occur, dryness of the lips and alimentary canal, loss of appetite, and constipation. The kidneys often secrete much pale urine, and often a cloudy deposit of phosphates; sexual weakness is common, or much sexual irritability occurs The mucous membranes are often painful, neuralgic feelings attack the roof of the mouth, the anal region, etc. The voice is weak, and some patients notice a change in its character—it sounding not like their own. The mental aspect is very difficult to investigate. Some patients are distinctly hypochondriacal; some, as those instanced by Griesinger, even to insanity; others have very indefinite hypochondriacal ideas, the fancy often changing, and ever within the bounds of possibility; others do not interpret their sensations as disease, but complain of great weakness and annoyance. They believe themselves to be suffering from no delusions, but are restless, irritable, and a peculiar mental cloud teaches them that they are not themselves. They suffer from marked melancholia, avoid society, and are weary of life. The mind is depressed, though there is no false motion of disease. The patients are conscious of a foreign element in their existence. It takes possession of their motor, sensory, and mental life. They are restless and sleepless, fear things and persons—morbid anticipation is often very marked, and weakness of will to act. They are highly conscious of themselves. The memory is poor, for want of exercise. The foreign attention in despite of the patient's determination absorbs all his faculties. Concentration of attention to work is impossible. A hypochondriac, in the usual sense of the term, cannot be reasoned with, his morbid fancies absorbing all his attention, but in the less severe forms where advice is sought in reference to loss of nerve-power, painful sensations, etc., it is always well to carefully observe the mental aspect of the patient, since we must hope for a cure by acting on our knowledge of this mental state, and not on the athletic means which are usually prescribed for this class of patients, such as cold baths, etc., which strike not at the real disease, which is a chronic perversion of mind, marked by depression, accompanied with uneasiness of sensation, loss of power, and other nervous phenomena.

Treatment.—The treatment naturally changes with the character of the case. The hypochondriacal patient cannot be reasoned with. Those cases where perverted mental ideas predominate are difficult to cure, and run through years of treatment. The less serious forms, and the common form which is designated by the word neurasthenia, is best aided by means which aim at the mental cure of the case, rather than to try and tone up the physical loss of power. The course of the malady is always extremely chronic; the less mental derangement the sooner the cure. In many cases the mental "cloud" is so slight as to be almost unobserved by the patient, yet he finds when this depression brightens up that all the other symptoms lessen; the neuralgias cease, the loss of power returns, the patient seeks society. On this account the proper treatment would be to act on the perverted disposition, divert the patient's attention, etc. As in more protracted and usually insane cases, when the patient feels himself he is returning to health, so likewise in those less manifest and slighter cases, all the symptoms disappear when this feeling of nominal self returns.

It is evident that up to the present day no medicine is of any utility in cutting short this hereditary perverted action of the brain, which is so curiously allied to the more serious form of mental aberration.

The so-called nerve-tonics are of very little good, and often cause distinct harm. Arsenic often flushes the head and heightens the sensory irritability and hyperæsthesia of the skin. The stimulants make the mental thought more distressed, no hilarity occurring as in ordinary brain action. The carbon-compound remedies are useless toward a cure, but relieve the pain and give sometimes a shade of more natural and peaceful brain action and cheerfulness. Bromides and chloral relieve sleeplessness best, and the former continued for one year may do much toward a cure. Blisters or plasters applied to painful parts are of little service. The hot bath is pleasant before bedtime, but depends more on the patient's frame of mind than on any special efficacy, as indeed do any other drugs employed. The patient is perhaps better left without physic. The bowels take

care of themselves. The dyspeptic derangements are vastly exaggerated and probably depend entirely on superficial pains in the skin over the stomach region. Headaches are often constant, and also depend on the sensations in the sensory nerves in the scalp. The weakness of sight recovers itself. Massage is undoubtedly the best remedy for the motor weakness and sensory pains—the very rubbing drives, as it were, the pain to other parts, and gives agreeable relief and sleep. Massage continued judiciously for six months would probably cure any ordinary case of so-called neurasthenia if the patient is satisfied to wait till the developmental errors of his brain aright themselves.

THE SUCCESSFUL TREATMENT FOR THE RESTORATION OF THE INJURED FEMALE PELVIC FLOOR.

By F. D. BRANDENBURG, A.M., M.D.,

CLEVELAND, O.

ACTING PROFESSOR OF GYNECOLOGY, WESTERN RESERVE UNIVERSITY; GYNECOLOGIST TO CHARITY HOSPITAL; CONSULTING GYNECOLOGIST TO CITY HOSPITAL, ETC.

The consideration of the most successful treatment for the restoration of the injured female pelvic floor is of the greatest importance, not only to the specialist in gynecology, but also to the general practitioner. The dark and gloomy picture of ever-increasing suffering and misery entailed by the neglect of injury to the pelvic floor, in happy contrast with the bright picture of relief and cure by its proper restoration, is so common, so apparent to the eyes of all, that it is unnecessary for me to offer any plea for its performance; but rather, it is my object to elicit a practical discussion, to call forth the opinions of the many able surgeons who are readers of the Record, so that the pathway of duty may be clearer as to what is the quickest and best method for the cure of a condition whose import is among the greatest. In order to fully understand the importance of this lesion, and also to give the desired relief, it is absolutely necessary, first of all, to have a due appreciation of what constitutes the normal pelvic floor. A mitral regurgitant murmur will have but little significance to the student who as yet does not fully understand the normal heart-sounds; the stethoscope is faithful in transmitting both normal and abnormal sounds, but we must know the first before we can appreciate the second.

Relaxation of the pelvic floor may present no visible lesion, but its importance may be far greater than a lesion apparent to all. This can only be fully appreciated by a study of the normal pelvic fascia and muscles. Allow me to briefly mention a few of the more important structures involved in the pelvic floor. The pelvic fascia is attached laterally to the brim of the pelvis, anteriorly to the lower portion of the symphysis pubis, posteriorly to the spine of the ischium, and to a tendinous band, the white line, joining these points. At the white line the pelvic fascia divides into the recto-vesical fascia and the obturator fascia. The recto vesical fascia, arising from the white line, extends downward and inward, covering the levatores ani muscles, and uniting in the median line with its fellow of the opposite side, forms the true fascial floor of the pelvis. This fascial diaphragm is perforated by the rectum and vagina, to each of which it is attached and gives firm support. The fascial floor is the girder, acting as a framework for the support of the various organs and complicated venous plexuses. The pelvic veins are without valves, but by their exceedingly tortuous course overcome the force of gravity. In relaxation of the pelvic floor, injury affecting the fascia, the blood vessels lose their support, become straighter and at the same time more distended, thus increasing the weight in the pelvis and giving rise to the dragging, bearing-down sensation so common in patients suffering from lesion to the pelvic floor. The levatores ani arise anteriorly from the posterior aspect of the pubes, near the symphysis; posteriorly from the inferior and inner surface of the ischial spine, and between these origins from the white line that represents the point of division of the pelvic fascia, they extend downward and inward and are attached to the vagina, the rectum, to each other, and to the tip of the coccyx by a ligamentous insertion. These form the muscular floor of the pelvis. The only other muscles which have any special importance are the transversus perinæi, which arise from the tubero-ischii and are inserted in the median line at the junction of the levatores ani and the pelvic fascia. It is the function of the transversus perinæi to keep the pelvic fascia tense and assist in keeping the vaginal walls approximated; but in a lesion to the pelvic floor their normal action is apt to be perverted by retracting the torn ends, increasing the gap, and making a bad matter worse. The fascial tension is more or less lost, air enters and balloons the vagina, causing sogging of the vaginal walls, followed sooner or later by retroversion uteri, cystocele, urethrocele, rectocele, amd prolapse in its various stages.

Injuries to the pelvic floor may be incomplete or complete. Under incomplete we have two varieties: First, in which the fourchette or vaginal mucous membrane may or may not be torn, perhaps no visible injury; but there is submucous injury to the fascial and muscular floors causing relaxation of the pelvic floor. Second, in which the muscular tissues are injured and lesion visible. In complete laceration of the perineal body, the sphincter ani is ruptured; and possibly more or less of the recto-vaginal septum; the ends of the sphincter will be found widely distant according to the amount of the fascial retraction, due to the perverted action of the transversus perinæi; the vagina and rectum being thrown into one common passage according to the extent of the lesion of the recto-vaginal septum. The pelvic fascia is not elastic; if tension is made in one direction, compensation must be made in another direction, and when this is not possible, rupture is the result.

In a remarkable case I found the perineum a hard ligamentous mass; there was present a large recto-vaginal fistula, the anus being very patulous; on inquiry I ascertained that the child had been born through the anus. Injuries to the pelvic floor from the use of forceps usually begin externally, first rupturing the fourchette and then the deeper parts; but when unaided the injuries are apt to begin internally, and we may have the various fistulæ resulting, and finally the loss of the perineal body.

Another factor of great importance is that of subinvolution of the vagina, the normal process of retrograde metamorphosis being retarded, owing to laceration of the cervix uteri, so apt to accompany severe lesion of the pelvic floor. Here it is necessary to repair the injury to the neck of the uterus, and thus assist nature in restoring again the uterus and vagina to something like their normal condition before one is warranted in repairing the lesion to the pelvic floor.

In the treatment of these lesions we must naturally consider, first the incomplete and then the complete laceration of the perineal body. Each case requires its own separate and appropriate treatment; no set rule can be applied to all cases. After a careful study of the normal pelvic floor, each case will readily suggest its own proper treatment. I care not what operation is used, so that the operator fully understands the amount of lesion present, and by his method is able to restore as nearly as possible the normal pelvic floor. Above all errors, there is none more deceptive than that of producing a skin perineum. The patient has been subjected to the inconvenience of an operation, but her condition has not been one whit improved.

The repair of the pelvic floor cannot be learned from text-books; it must be seen to be fully appreciated and understood.

Again, the matter of diagnosis is sometimes obscure. I was called to see a lady suffering from incontinence of fæces; she had been delivered of a child three months

previous. Her family physician assured me there was no local difficulty; but on examination I found a complete laceration of the perineal body, also a tear up the recto-vaginal septum for fully an inch and a half, fully accounting for all of the patient's symptoms. On restoring the pelvic floor her disagreeable symptoms were at once cured. I may also add that in this case, as in many others, the baby was kept from the mother's breast for twenty-four hours immediately following the operation, and then again allowed to nurse; this is very important, as there is no agent more powerful to produce involution than that of nursing; it is nature's way of producing retrograde metamorphosis, and when this law is violated the patient invariably pays the penalty. When attending a case of labor always have your sutures ready for any possible lesion which may occur; having trimmed off any tags that may be necessary, the sutures can be readily and quickly introduced, for the parts are then benumbed; there will be union by first intention, a normal restoration of the pelvic floor, involution hastened, and the patient spared months or even years of suffering. In tying your sutures they should be snugly but not too tightly secured, and thereby avoid any difficulty from the tumefaction of the reparative hyperæmia; this applies to any period. Avoid multiplicity of sutures. Use as few sutures as possible consistent with the proper coaptation of the torn parts. I have seen twenty, thirty, and even still more sutures used in complete laceration of the perineal body involving the recto-vaginal septum. I have also seen failures which, I am fully convinced, were due entirely to the multiplicity of sutures. It is to be remembered we are dealing with erectile tissue, and with such a profusion of sutures how else can it be but that the circulation is disturbed; an interference with the normal action of the vaso-motor apparatus, and we have the classical symptoms, rubor, calor, tumor, dolor, and functiolæsa. The consequent abscess cavity is obliged to fill by granulation, and while it may not lessen the strength of the pelvic floor, it is decidedly annoying to the patient.

In preparing a patient for perineorrhaphy, especially in case of complete laceration of the perineal body, much of the success of the operation depends on the previous attention to regulation of diet and action of bowels. It is my custom to begin fully one week before the operation with regulation of diet. Three days before the operation, calomel, ipecac, and soda tablets, containing calomel, $\frac{1}{4}$ grain, are given hourly till one grain is taken. Two days before the operation several free movements of the bowels are secured by the use of Rochelle or Epsom salts; and the day before the operation the lower bowel is throughly emptied by enema. For fully twelve hours or more before the operation the bowels are perfectly quiet and remain so till three days after the operation, as will be described later when speaking of the after-treatment.

With the patient before you, anæsthetized and in the dorsal position, map out carefully the extent of the lesion, as indicated by the caruncles or scars; with the tenaculum picking up a point on the crest of the rectocele or central portion of posterior vaginal wall, and bringing it down to the topmost caruncles on either side as already noted, so that the slack of the posterior vaginal wall will be taken up and become slightly tense. Through this point in the posterior wall a suture can be passed and be useful as a guide during the operation, and then removed when sutures are in place. Beginning at scar on left side, denude a strip at edge of the vaginal mucous membrane, down along fourchette and up to scar on right side; then beginning again at same point on left side, denude a strip across the left angle to the point on the crest of the rectocele, and continue across right angle till end of first denudation on right side is reached. You have now mapped out before you the ordinary butterfly diagram. Still the borders denuded the intervening tissue can quickly be removed; in denuding avoid the vessels as much as possible, especially the venous plexuses; scissors and tenaculum being used in the denudation. If the scar extends up either angle, or there is marked relaxation, a triangular denudation should extend up the same. Small spurters can easily be controlled by the mere application of the artery forceps; but if a vein has been injured, it should be carefully ligated and clot removed. When completed, the denudation should be the same height on either side, and as nearly uniform as possible. In suturing I prefer the figure-of-eight suture, using heavy silkworm-gut and the Hagedorn gynecological needle, one-half or full curve. If the angle has been denuded, a figure-of-eight suture should be introduced, with the ends of the suture at base of triangle, then using two figure-of-eight sutures for the trefoil denudation.

Two sutures are sufficient for an ordinary laceration; if the angles are involved, then one for each angle. With the left index-finger in the rectum as a guide, the sutures should be buried as deeply as possible to catch up and bring together the torn or relaxed ends of fascia and muscle. Placing a small loop of thread on base of suture, it facilitates the removal of suture at end of eight days.

Silkworm-gut commends itself for the ease with which it can be made aseptic, and its lack of irritation to the surrounding tissues.

It is very rare to have pus from its use, and it gives but little pain to the patient. In securing the sutures, the limbs, which had been strongly flexed, are now brought forward, the knees being held tightly together. A tenaculum is placed in the angle at the base of the denudation, and downward traction is made, thus lengthening the denuded portion. The torn or relaxed pelvic floor is now brought together to its normal position, and by thus taking up the slack in the pelvic fascia, giving the blood-vessels their necessary support, it also soon assumes its normal condition. The successful performance of repair for complete laceration of the perineal body is one of the most difficult feats of plastic gynecology. All that has been said about incomplete laceration of the perineal body applies also to complete, with the exception that, beginning at the retracted ends of the sphincter ani muscle, careful denudation should be made about the rectum, down to, but avoiding injury of, the rectal mucous membrane. After the sutures already described are inserted, with the addition of a few transverse sutures if the amount of lesion is very large, last of all I unite the rectal mucous membrane, using a continuous suture of small-sized catgut and one-half curved needle with smooth, round point; having tightened my first layer of sutures, and the edges of the rectal mucous membrane being in perfect apposition, I then use a second layer, and even a third layer of sutures if necessary, bringing in surrounding tissues and strengthening the same; lastly, with the knees in the proper position, the remaining sutures are secured as already described. In both classes of cases the after-treatment consists in keeping the patient quiet on dorsal position, giving hot douches, using Küstner's glass catheter if patient is unable to urinate easily. No dressing is used on the perineum.

On second day after the operation, calomel, ipecac, and soda tablets are given as before operation, and on third day a saline cathartic is given. The first movement should be soft and liquid, and especially so in cases where the rectum has been involved: in those cases an enema containing glycerine and Epsom salts should be carefully given, using pressure with tip of syringe backward toward coccyx, thus avoiding the slightest tension on sutures.

Daily movements should afterward be secured by appropriate medication. Union by first intention is secured in these cases, and success will crown your efforts if the proper care is exercised. In the treatment of a case of complete laceration of the perineal body, just as much care should be exercised as in the treatment of a severe fracture. In the one we have exudate, in the other callus. In both cases it takes time and rest for

the parts to solidify and become strong. This should be firmly impressed upon your patient. Some surgeons prefer daily movements of the bowels immediately following the operation, by the administration of continued small doses of a saturated solution of Epsom or Rochelle salts. Others prefer constipation for a week or more, even using opium to accomplish the same. In the first instance the constant vermicular action is apt to prevent complete union; and in the second, the accumulated scybalæ are apt to do damage to the newly united tissue. The golden mean of Horace applies here as well as in many other cases. The object attained is paramount to the agency employed; whether you are the disciple of an American or a European, the speedy and thorough restoration of the injured pelvic floor is the goal, *par excellence*, to be reached. I am happy to state it has now reached a stage of development which insures not only relief and cure to the patient, but also a reasonable degree of satisfaction to our worthy leaders after their years of tireless exertion.

99 Huron Street.

THE SECRETION OF HYDROCHLORIC ACID BY THE STOMACH IN HEALTH AND DISEASE.

By M. GROSS, M.D.,

New York.

According to Rollett and Heidenhain the difference between the gastric glands at the pylorus and the fundus consists in the fact that the former contain only small bright nucleated cells (Heidenhain's Hauptzellen = main cells), while the latter have, in addition, the spherical large cells adjoining the membrana propria (Heidenhain's Belegzellen = covering cells). Heidenhain ascribes to the main cells the formation of pepsin; to the covering cells, the formation of hydrochloric acid.

The elaboration of the gastric juice is divisible into two separate acts: the supply of the raw material by the blood to the points of secretion, shown by the vivid reddening of the gastric mucous membrane coincident with the beginning of the secretion; and the chemical transformation of a portion of this material into the specific constituents of the gastric juice by the gland cells.

The mere fact that an acid secretion is formed from the alkaline blood bears witness to the specific activity of the gland cells.

In what manner is free hydrochloric acid formed in the gland cells from the sodium chloride supplied by the blood? H. Schulz has shown that alkaline chlorides in watery solution are decomposed by carbonic acid, small quantities of free hydrochloric acid being formed. Since the blood circulating around the glands contains large amounts of free carbonic acid, the combined effect of this acid can liberate a small quantity of hydrochloric acid from the sodium chloride. As it is probable that the formed free hydrochloric acid is almost immediately expelled from the gland, the carbonic acid can again displace a small amount of hydrochloric acid and thus the process of transformation may continue. While the gland cells expel the liberated hydrochloric acid into the efferent duct of the glands of the fundus, the carbonate of sodium formed at the same time passes back into the lymph and blood-current (J. Munk).

Under normal conditions, as has been proved in the case of fistula, the mere contact of a foreign body with the gastric mucosa stimulates the secretion over a circumscribed area corresponding to the surface of contact. But the secretion occurring in consequence of the mechanical irritation is insufficient; it becomes at once more energetic and loses its circumscribed character if absorption, though it be only of water, takes place at the same time. The glandular activity becomes general over the whole of the stomach and assumes its normal degree when the organ contains nutritive fluids, which seem to exert a powerful influence on the secretion, probably in a reflex way. It is a well-known fact that the swallowing of the tube by sensitive individuals may be a sufficient stimulus for starting the secretion.

The first phenomenon which we can demonstrate in all normal gastric contents at the height of the digestive process is their acid reaction, which is due chiefly to the excreted hydrochloric acid and to a slight extent to the acid salts present in the contents of the stomach. At this period the acidity is greatest; it rises gradually to this point from the onset of digestion, and again slowly decreases. At the moment in which the gland cells are stimulated into activity by the ingesta the secretion of hydrochloric acid begins, and the latter at first forms salts or hydrochlorates with the inorganic and organic bases, giving rise to chlorides and hydrochloric albuminates. In testing these combinations litmus-paper will turn red, but free hydrochloric acid cannot be demonstrated. Sooner or later, however, saturation occurs, and as the glands meantime continue to secrete, free hydrochloric acid then appears, which reaches its maximum at the height of digestion and then lessens (Ewald).

After Ewald's test breakfast (a cup [⅓ litre] of tea and a roll weighing 35 gm.) the maximum of the secretion of hydrochloric acid coincides with the beginning of the second hour, and the hydrochloric acid secreted about this time amounts to 0.15 to 0.2 per cent; after a plentiful mixed diet the maximum of hydrochloric acid secretion ensues later. Although these figures are not invariable, they are so nearly correct that great deviations above or below them must be looked upon as pathological.

As opposed to the normal scretion of hydrochloric acid (euchlorhydria), we speak—1. Of an anomalous secretion of hydrochloric acid when we have to deal with a retardation or acceleration of the otherwise normal acid, that is to say, when the maximum secretion occurs much later or earlier than the time above given. 2. The secretion of hydrochloric acid may be diminished (hypochlorhydria. 3. The secretion of hydrochloric acid may be increased (hyperchlorhydria). 4. Hydrochloric acid may be completely absent (achlorhydria). 5. There may be combinations of the above enumerated anomalies of secretion.

If we bear in mind that disturbances in the secretion of hydrochloric acid (defect or access) may occur (*a*), when the quality of the blood is morbid, thus favoring or impeding the secretion of hydrochloric acid; (*b*), in disorders of the glandular apparatus in consequence of inflammatory processes, ulceration, etc.; (*c*), in central and peripheral disorders of the vago sympathetic system; (*d*), in combinations of the last-cited factors, we must agree with Boas, who states that an anomaly in the secretion of hydrochloric acid *per se* does not indicate with any degree of certainty the existence of a disease of the stomach.

The access or diminution of the secretion of hydrochloric acid is a symptom which indeed bears some relation to the different types of disease, inasmuch as some have a decided tendency to increase the secretion, others to decrease or suppress it altogether. But this takes place only to the extent in which the various morbid processes are associated with anatomical or functional disturbances which naturally cause an alteration in the production of hydrochloric acid; hence it is the degree of this factor in the morbid process which determines to what extent the secretion of hydrochloric acid is involved. Admitting that nowadays, owing to successively perfected methods of examination and daily increasing clinical observations resting on a strictly scientific basis, we are on a firmer footing in arriving at a correct diagnosis or in recognizing the indications for a successful treatment; yet it is true to day, more than ever, that only the most careful consideration and appreciation of all the symptoms developing in the course of the disease, aided by all the diagnostic auxiliaries, will make clear the nature of the affection we have to deal with.

When we consider the anomalies of secretion of the several diseases of the stomach we find in acute gastritis almost exclusively a lack of hydrochloric acid; the sour

eructations and vomiting in this affection are usually due to acetic, lactic, and butyric acids.

In chronic forms of gastritis we recognize above all the law of pathology, that chronic inflammations restrict or paralyze the specific activity of the respective organs. In those cases in which, despite the inflammatory condition of the gastric mucous membrane, there is hyperchlorhydria, the inflammatory symptoms are of a secondary nature, being merely sequelæ or concomitant phenomena of the over-production of the secreting apparatus due to other, usually nervous, causes. In such cases the hyperchlorhydria exists in spite of the partial lesion of a part of the secreting parenchyma, as the expression of an increased activity of the intact remainder (Ewald).

In simple chronic inflammation (gastritis chronica simplex) the hydrochloric acid is always diminished; in mucous inflammation (gastritis chronica mucosa) the hydrochloric acid is usually completely absent; in the atrophic form (gastritis chronica atrophicans) we note complete absence of combined and free hydrochloric acid, *i.e.*, of all the hydrochloric acid which is physiologically active. In the chronic forms of gastritis, too, we often find, in consequence of the formation of acetic, lactic, and other acids, eructations and rising of acid material which blunts the teeth and causes also a burning, scratching sensation in the course of the œsophagus, the so called heartburn or pyrosis; the latter sensation, if confined to the cardia, is also called cardialgia. The cases, however, which are associated with an intensification of the acidity of the normal gastric juice, *i.e.*, with hyperchlorhydria, and those periodical cases in which the acidity and quality of the gastric contents are normal, despite the symptoms of pyrosis, as shown by MacNaught,[1] should be, with few exceptions, included among the neuroses, as indicated above.

In atonic conditions of the stomach, as I have had occasion to prove,[2] we find the secretion of hydrochloric acid variable in accordance with the state of the gastric mucosa.

In dilatation, however, the chemical composition depends on the cause of the dilatation. In dilatation of the stomach, in consequence of cicatricial stenosis of the pylorus and atonic conditions of the muscular structure, we find almost exclusively a normal or increased amount of hydrochloric acid in the contents of the stomach. The hydrochloric acid may vary in the same patient on different days despite an unchanged diet. In dilatation of the stomach we not rarely find the condition called continuous acid hypersecretion, in which the stomach, after being emptied in the evening, contains the next morning often considerable quantities of fluid charged with hydrochloric acid, a point to be discussed hereafter. All this shows that the stagnation of the gastric contents exerts no perceptible influence upon the secretion of the gastric mucosa, as long as its secreting elements in general are preserved.

The diagnosis of ulcer of the stomach seemed to gain greatly in certainty by the fact that it was thought an excessive formation of acid could be demonstrated as a constant symptom. The credit of having first emphasized the occurrence of an increased secretion of hydrochloric acid belongs to Riegel. Ewald declares: In ulcer of the stomach the gastric juice always contains hydrochloric acid, often excessive in amount. More recent experience, however, has proved that while hyperchlorhydria is frequent in ulcus ventriculi, it is by no means constant.

V. Korczynski, and Jaworski, too, found in some cases also an untimely—*i.e.*, occurring in the empty stomach—so-called continuous acid hypersecretion. Removal of the contents of the stomach will show that such acidity disturbs the digestion, the protolytic being rapid and complete, the amylolytic slow and defective; in other words, all the meat is often well digested, while of the starchy matters a greater or less residue is found. Golding-Bird[1] first described the state of the hydrochloric acid in a case of cancer of the pylorus with dilatation. Kussmaul and his pupils, however, were the first to treat this question methodically, and have shown that in the large majority of cases of gastric cancer free hydrochloric acid is absent, although such absence in this disease has no specific importance and possesses merely the value of a secondary symptom. More recent investigations have disclosed additional no less interesting points. When the carcinomatous new-formation occupies a small region, and the associated inflammation of the gastric mucosa is slight, the secretion of hydrochloric acid may continue to be sufficient; a possible subsequent lack of hydrochloric acid may be the result of the slowly developing cachexia. When the carcinoma springs from the bottom of a gastric ulcer, there may be at first even normal secretion of hydrochloric acid, or perhaps hyperchlorhydria. In the majority of cases, however, as stated above, there is not only an absence of free hydrochloric acid, but also of that loosely combined with salts. Yet this lack of hydrochloric acid does not depend upon the carcinoma *per se*, but on the associated catarrhal inflammation or the atrophic condition of the gastric mucosa.

Ewald describes a case which proves that when the cancer is localized and the mucosa intact the secretion of hydrochloric acid may continue until a short time before death. In this case carcinoma developing on an ulcer could be excluded.

While some authors look upon hyperchlorhydria and hypersecretion as an anomaly of secretion in consequence of organic lesions, and only in a small number of cases as a neurosis, Ewald, among others, maintains that in most cases, excepting those above enumerated, we are dealing with a pure neurosis of secretion. In the succeeding sentences I am following mainly Ewald's deductions. This author looks upon hyperchlorhydria and hypersecretion of the gastric juice as a sensory neurosis of the secretory sphere. Of these two conditions the hyperchlorhydria, which must be strictly separated from hypersecretion, consists in an increase of the normal hydrochloric acid secretion, this excessive activity being due to the irritation of the ingesta. Van Norden found hyperchlorhydria as a primary neurosis, *i.e.*, independent of an organic lesion, in melancholia; Jolly, in hysteria. It occurs temporarily as a reflex phenomenon after gall stone colic and renal calculi.

Hypersecretion or parasecretion, Reichmann's "Magensaftfluss," is divided into the acute or periodical, and the chronic or continuous form. The former occurs, as a rule, without increased acidity. It appears periodically, usually after eating, rarely on an empty stomach, but seems to have no direct connection with the introduction of ingesta. The condition is a functional disturbance of the nerves of the stomach, which occurs independently or as a local symptom of other neuroses.

In chronic hypersecretion there is a continuous formation of gastric juice, which is usually excessively acid, so that even the empty stomach contains larger or smaller quantities of a fluid which may vary greatly in the contained free hydrochloric acid, but whose degree of acidity is always increased. In this condition, too, while the tongue is remarkably clean and the appetite good, we find, as a consequence of the irritation due to the acid fluid, heartburn, gastralgia, etc., which troubles disappear temporarily after an albuminous diet, contrary to the pyrosis resulting from acid fermentation, in which albuminous diet has no ameliorating effect.

There is also a nervous anacidity (anachlorhydria) of the gastric juice in hysterical and neurasthenic patients in whom, therefore, an organic disease of the stomach can be excluded.

The relations between the secretion of gastric juice and the diseases of other organs of the body have an

[1] Medical Chronicle, January, 1885.
[2] Atony of the Stomach, MEDICAL RECORD, March, 1894.

[1] London Medical Gazette, 1842, vol. ii., p. 391.

importance which must not be underestimated, for there is hardly any internal disorder in which gastric digestion is not largely implicated and associated with functional disturbances. This subject is so extensive that I must dispose of it here in a few words.

In diseases of the heart, lungs, and liver it is mainly the circulatory disturbances which lead to symptoms of congestion and their sequelæ, chronic catarrhal conditions of the gastric mucosa.

Diseases of the heart *per se* have no influence on the secretion of hydrochloric acid; it is the chronic catarrhs resulting from congestion which cause a diminution of the secretion of hydrochloric acid.

In diseases of the nose I have made investigations with the muco-purulent masses from a purulent rhinitis and have found that the digestive power of an active gastric juice is weakened by the addition of such nasal secretions; small amounts of hydrochloric acid may thus be neutralized when the secretory activity is depressed.

In chronic diseases of the lungs, in phthisis, emphysema, in chronic forms of bronchitis, etc., in which, as stated above, circulatory disturbances and their consequences come in question with reference to their influence on the secretion of hydrochloric acid, it depends entirely on the extent of the anatomical and functional disturbance present in the concrete case to produce a corresponding effect on the gastric glands.

Hildebrand found that the absence of hydrochloric acid in phthisis coincided with the rise of temperature. As regards diseases of the kidney[1] Fenwick proved that in chronic renal diseases the gastric mucous membrane likewise excretes urea, and that the latter during the process of elimination irritates the mucosa of the stomach and leads to catarrh, with consequent diminution of hydrochloric acid. Bernacki found that during oliguria and œdema the diminution of hydrochloric acid was greater than after the re-establishment of the urinary secretion and the disappearance of the œdema; as the quantity of urine increased, so did the hydrochloric acid.

As regards the disturbance of hydrochloric acid secretion resulting from diseases of the sexual organs, E. Fleischer found diminution of the acid during menstruation. Recently I treated a neurasthenic patient who was attacked after nearly every coitus with nausea and gastralgic pains, sometimes associated with vomiting; the vomited matters always contained excessive amounts of free hydrochloric acid.

Rosenheim found in a number of diabetic patients a temporary absence of hydrochloric acid which he interpreted as a neurosis; in other cases he found the hydrochloric acid constantly absent and ascribed the condition to an atrophy of the glandular apparatus.

In anæmia and chlorosis the activity of the gastric glands suffers in consequence of defective blood supply; but there are cases enough in which the secretion of hydrochloric acid is normal or even excessive.

Lastly, with reference to the secretion of hydrochloric acid in malaria, I have found among fifteen cases of masked malaria—further details will be given in another place—nine in which the hydrochloric acid was diminished, while lactic acid was markedly increased.

In conclusion, I shall give the shortest methods for the qualitative and quantitative determination of hydrochloric acid. By means of Congo paper we ascertain whether any free acid is present in the filtered gastric contents; paper impregnated with Congo red becoming violet in the presence of acids. To determine free hydrochloric acid we employ Günzburg's reagent and mode of procedure. The reagent consists of phloroglucin, 2; vanillin, 1; alcohol (eighty per cent.), 100 parts. Of this solution we place one or two drops in a china saucer and add one or two drops of the stomach contents to be tested. If free hydrochloric acid is present, a carmine red ring forms at the point where the two fluids meet when the saucer is carefully heated.

[1] Virch. Arch., Bd. xviii.

For the quantitative determination of hydrochloric acid Leo's method is the most reliable:

Any present organic acids having been determined and removed, 10 c.c. of the filtered stomach contents are mixed with 5 c.c. of a concentrated solution of calcium chloride ($CaCl_2$) and its acidity is determined. Then 15 c.c. of the filtrate are mixed in a dry vessel with dry chemically pure powdered calcium carbonate ($CaCo_3$), and after stirring are run through a dry filter. Of this filtrate 10 c.c. are measured off, and air is passed through to drive off the carbon dioxide (CO_2); then 5 c.c. of calcium chloride ($CaCl_2$) is added and the filtration is repeated. The difference between the first and second filtration shows the physiologically active hydrochloric acid.

Progress of Medical Science.

Putrefactive Gases as Predisposing Agents in Typhoid Infection.—Dr. Alessi has made experiments which throw some light upon this subject. Rats, guinea-pigs, and rabbits were confined in boxes with perforated bottoms, and these boxes were then placed over open privies or cesspools, or over receptacles containing the evacuations of the animals. Notwithstanding that they continued to eat well, the animals lost their liveliness, and gradually pined. They were inoculated in this state with a small dose of typhoid bacillus, with the result that they died in twelve to thirty-six hours. The examination showed signs of hæmorraghic enteritis, swollen Peyer's patches and spleen, and typhoid bacilli in the blood, liver, and spleen. The same dose had no effect upon the majority of the control animals; only a few showed slight symptoms of illness, and one died. These experiments go to show that animals are rendered highly sensitive to the typhoid bacillus by previous inhalation of the gases of putrefaction. Alessi next investigated the isolated action of the various gases produced in putrefaction, to ascertain if any one were capable of creating the predisposition referred to. The result was in each case negative. The same held good as regards certain mixtures of these substances.—*Centralblatt für Bakteriologie.*

Toxicity of Scalded or Burnt Tissues.—In 1880 Lesser made some experiments to ascertain the effects of injecting the blood of a burnt animal into a healthy one. He seems, however, to have succeeded only in producing certain functional disturbances, never a fatal effect. Vassale and Sacchi followed a similar line of investigation, and studied the effect of extracts of parts actually burnt or scalded, and of the non-affected parts of the same animals, on healthy animals of the same or allied species. Their researches show clearly that the juice of parts burnt has a much more toxic effect on animals of the same species than that of the non-burnt parts of the same animal. This last juice, in its turn, has a toxicity much greater than that of the juice taken from corresponding parts of a healthy animal, which is, in fact, harmless. All the juices from a burnt animal are highly toxic, and generally produce lethal effects whether injected hypodermically or into the veins of normal animals. The chief pathological effects produced were marked subserous hemorrhages, in one case especially marked in the duodenum. Filtration through porcelain somewhat diminishes but does not destroy the toxicity of the juices; boiling, however, renders them innocuous, which lends support to the view that the toxic principle is an albumose, or some substance coagulable by heat. These results are of interest as bearing on the mode of production of the after effects of burns, attributed by Foá, as early as 1881, to a process of autointoxication. Not long ago Kianitzin (*Ann. di Chim. e di Farmacol.*, 1892) examined the blood, organs, and urine of animals suffering from burns, and by Brieger's method obtained a substance from them which was not

to be found in normal animals similarly treated. When injected into normal animals it produced torpor, somnolence, reduction of temperature, slow, shallow respiration, diarrhœa, and death. The necropsy showed nothing but hyperæmia of the brain and kidneys. This substance was classed by its discoverer with muscarin, neurin, and peptoxin. More recently Reiss (*Archiv für Dermatologie und Syphilis*, i., 1893) studied the effects of subcutaneous injection of the urine of patients suffering from burns. Such urine was very toxic, and it was found that it owed its properties to the presence of bases of the pyridin group. In cases of severe burn he recommended the speedy removal of the sloughed parts so as to minimize the absorption of poisons formed in the lesion. Vassale and Sacchi are of a similar opinion. They also recommend the employment of every possible means—such as keeping the burnt limb as low as possible, and the application of bandages—of preventing the too rapid absorption of the degeneration products, the toxicity of which they have so fully established.—*The British Medical Journal.*

The Nephritis of Typhoid Fever.—In a recent article on this subject by M. Léonce Bodin, the author remarks that the forms of nephritis that supervene during the course of typhoid fever are well known clinically (*The New York Medical Journal*, August 11, 1894). They occur most commonly in patients affected with the classical form of dothienenteritis, with high fever, diarrhœa, rose-spots, tympanites, enlargement of the spleen, and a more or less pronounced typhoid condition. The renal accidents usually make their appearance during the course of the second week. Albumin appears suddenly and more or less abundantly in the urine, and its appearance is accompanied by general phenomena of variable intensity. When these phenomena are violent, as sometimes happens, they deserve the name of acute uræmia, being accompanied by almost complete suppression of urine and by œdema, and almost always terminating fatally by convulsions or coma. In another form they are less violent, but they are always grave. There is blood in the urine, which is diminished in amount, and the uræmic phenomena are less intense. Finally, and more frequently, still less severe derangements are observed, characterized especially by an aggravation of the general condition, by dryness of the tongue, by pains in the loins, by headache, and by the appearance of a slight amount of albumin in the urine. It is particularly in this third form, happily the most frequent, that there is especially to be observed an exaggeration of the symptoms proper to the typhoid fever, but with a very clear renal character easily recognizable. In these forms of nephritis microbes are generally found in the urine, or, but much more rarely, in sections of the kidneys. Ordinarily they are micrococci, with or without the bacillus of Eberth, streptococci, and staphylococci, the last-named being far the most common. As these microbes are habitually found in the intestinal canal, it is very probable that they gain entrance into the blood through the intestinal ulcerations, which are an open door to all secondary infections; consequently, these cases of nephritis of typhoid fever are most commonly cases of secondary nephritis.

But typhoid nephritis may present various guises, and the case reported showed very special characters in its evolution, so that it seems to the author to be an example of a particular class of cases, both clinically and bacteriologically. The patient, twenty-three years old, was a night nurse employed in the Trousseau Hospital. She was admitted into the Saint-Antoine Hospital on June 1st. For about a week she had suffered with progressive loss of strength, great lassitude on the slightest exertion, invariable fatigue on rising, progressive and persistent impairment of sleep, and continuous headache which resisted antipyrine. She had lost her appetite and had vomited a few times, but had no diarrhœa or bleeding from the nose. On examination, the abdomen was found soft and not distended; there was no gurgling in the iliac fossa or pain anywhere on pressure; the tongue was lightly coated and pale, but neither red at the tip or at the border nor tremulous. There were no rose-spots on the abdomen. After a minute search two or three doubtful eruptive spots were found on the back, between the shoulder blades and on the lumbar region. The spleen seemed somewhat enlarged. The temperature was 102.1° F. in the morning and 104 2° F. in the evening. The lungs were normal, and the patient's general condition was good—she had no stupor, but slight prostration. The urine was normal. After hesitating between influenza and typhoid fever, the latter was diagnosticated. On June 5th it was noted that during the night the patient had vomited abundantly and that the matter vomited was greenish; also that her general condition was aggravated and that there was some stupor, with severe headache, lumbar pains, and dryness of the tongue. The urine was of a deep red color and contained a notable quantity of albumin. The temperature, which had at first been kept down with quinine, had now risen to 104.3° F. Baths of the temperature of 66° F. were prescribed every three hours. On the 6th many red blood-corpuscles were found in the urine, also blood-casts and epithelial *débris*. Albumin was found in the urine until the 25th, after which it was present only as a slight trace for a day or two and then disappeared definitely and the patient was in full convalescence. M. Bodin calls attention to the fact that during the whole course of the disease at no time were the ordinary abdominal and pulmonary symptoms of typhoid fever observed, only a moderate prostration during the early days. The temperature curve was that of typhoid fever of medium intensity, but the onset of the symptoms of nephritis had been very definite and had impressed upon the disease a particular aspect. The small amount of albumin found in the urine and the absence of oliguria, save at the outset, are to be contrasted with the very decided uræmic phenomena present from first to last.

The bacteriological examination of the patient's fluids was made as follows: Beginning with June 6th, the urine was collected every second day, examined, and inoculated. On three occasions the blood from the spleen was inoculated. The urine was removed from the bladder with a sterilized metallic catheter after a thorough cleansing of the vulva and meatus urinarius with soap and a solution of corrosive sublimate. The urine, received into sterilized tubes, was placed on a centrifugal machine and cultures were made in gelose, gelatin, or bouillon directly from the deposit thus obtained. The blood was taken from the spleen by means of a Roux's syringe boiled for an hour, and after previous disinfection of the skin over the spleen. It was ascertained that from beginning to end the urine contained a very great abundance of bacilli having all the characteristics of the Eberth-Gaffky bacillus. The existence of this bacillus exclusively in the urine is considered remarkable by the author, for most commonly in analogous cases there are numerous associated microbes, especially staphylococci. Furthermore, from the complete absence of the ordinary intestinal symptoms of typhoid fever, he thinks it probable that in this case the intestine was but slightly if at all affected, so that there could not have been a secondary infection by the microbes which are ordinarily found in the alimentary canal. The author hazards the hypothesis, which he confesses is somewhat forced, of a primary nephritis from infection with the Eberth bacillus, or nephro typhus accompanied by a general condition and a temperature curve resembling those of typhoid fever without any of the usual symptoms of typhoid fever pertaining to the alimentary canal, the lungs, etc. Granting this to have been the case, the Eberth bacillus would have acted in this case as the pneumococcus acts in certain kinds of amygdalitis in which the thermometric curve and the general condition of a frank pneumonia are observed without the slightest local sign of pulmonary inflammation.

Clinical Department.

FOUR CASES OF RETINITIS FROM CHRONIC DIFFUSE NEPHRITIS.

By DAVID WEBSTER, M.D.,

PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC AND IN DARTMOUTH MEDICAL COLLEGE; SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, NEW YORK.

CASE I.—Mrs. E. R——, aged sixty-three, consulted Dr. C. R. Agnew and myself on December 2, 1879. She had had poor sight for many years, but could read until three months ago. During the last three months her sight has deteriorated rapidly.

R. V. = $\frac{20}{100}$; no improvement with glasses.

L. V. = counts fingers at one foot.

Ophthalmoscopic examination shows incipient cataract of both eyes. The right has a large plaque of retinal exudation in the region of the macula. The left has neuro-retinitis with numerous hemorrhages of various sizes and shapes scattered all over the fundus.

All the urine Mrs. R—— passed in twenty-four hours was sent to Dr. E. A. Maxwell for examination. Dr. Maxwell reported as follows: 1, Medium and broad hyaline casts; 2, epithelial and granular casts; 3, no albumin; 4, low specific gravity; 5, large quantity of urine. Chronic diffuse nephritis.

CASE II.—June 25, 1880. James W——, aged sixty-eight, manufacturer and merchant, married, never saw well in the distance. He can read at the ordinary distance without glasses. For the last two or three weeks his eyes have failed in reading and he has seen motes and black threads and dark spots floating before them. He has had no pain in his eyes and no headache. He has been troubled a good deal with dizziness on stooping or on suddenly turning his head. He has had a cough for four or five years, and is weak and short of breath.

R. V. = $\frac{20}{100}$; $\frac{20}{50}$ with $-\frac{1}{36}$.

L. V. = $\frac{20}{100}$; $\frac{20}{30}$ with $-\frac{1}{18}$.

As his pupils were very small that of the right eye was dilated by means of an atropine wafer, to facilitate ophthalmoscopic examination. We found floating bodies in the vitreous and minute clusters of changes in the retina at the posterior pole of the eye.

June 26th.—Since the atropine wafer was put into the eye there has been smarting and sensitiveness to light. His bowels are perfectly regular. Ordered iodide of potassium, gr. v. *ter in die*.

On June 30th his urine was examined by Dr. E. A. Maxwell, who reported as follows: 1, Concentrated urine; 2, no albumin nor sugar; hyaline, hyaline and granular casts, medium and narrow, six to eight on a slide; 4, yellow, finely granular, tubular epithelium; 5, altered blood-corpuscles, scanty; 6, spermatozoids, scanty; 7, oxalate of lime. Chronic diffuse nephritis, granular contracted kidney, general or localized.

Examination of a second specimen four days later gave similar results.

CASE III.—September 17, 1880. John T. R——, aged sixty eight, married, says that he did a great deal of writing last February and from that time till five or six weeks ago he had a great deal of difficulty in reading, and since that he has not been able to read ordinary print at all. He comes up stairs with difficulty, due, he says, to rheumatism, which he has had, more or less, since 1868. He had it very badly at one time, but was never laid up in bed with it. He has been, for two or three weeks at a time, so crippled with it that he had to crawl up stairs and slide down. He has a poor appetite, and dizziness, and constipation, the latter for the last two years. He seldom takes physic, however.

Ophthalmoscopic examination shows peripheral opacities in the lower parts of both crystalline lenses. There are old corneal opacities of the right, and both have an astigmatic look. There are changes about the macula, and a large area in that region looks somewhat œdematous, or hazy. Both anterior chambers are markedly shallow.

R. V. = $\frac{6}{200}$; $\frac{20}{180}$ with $+\frac{1}{8}$.

L. V. = $\frac{20}{100}$; $\frac{20}{50}$ with $+\frac{1}{8}$.

A specimen of his urine, examined by Dr. Maxwell, shows: 1, Quantity and specific gravity normal; 2, medium and broad hyaline casts; 3, tubular epithelium; 4, pigmented bladder epithelium; 5, no albumin nor sugar. Chronic diffuse nephritis.

CASE IV.—February 25, 1882. Thomas A——, aged seventy-one, married, merchant, complains of a blur over his right eye with scintillations. He says he was always near-sighted. He is the victim of rheumatic gout, and his family physician says he has organic disease of the heart.

R. V. = $\frac{20}{60}$ with $-\frac{1}{6}$.

L. V. = $\frac{20}{60}$ with $-\frac{1}{15}$.

Ophthalmoscopic examination shows staphyloma posticum of both eyes, that in the right being very extensive. In the right eye there are retinal exudations occupying the whole macular region.

Dr. Maxwell examined his urine and found: 1, Light color; 2, low specific gravity (1017); 3, no albumin nor sugar; 4, abundant hyaline casts (10 or 12 on a slide); 5, scanty, altered tubular epithelium. Chronic diffuse nephritis.

It is worthy of remark that there was no albumin present in the urine of any of these patients. The diagnosis of chronic diffuse nephritis was based on the presence of casts, and other abnormal constituents of the urine.

A FEW WORDS IN REFERENCE TO CARYOCINETIC CHANGES IN THE RED BLOOD-CORPUSCLES.

By WILLIAM MOSER, M.D.,

PATHOLOGIST TO ST. CATHARINE'S HOSPITAL, BROOKLYN, N. Y.

EVER since Luzet drew attention to caryocinetic changes in the red blood-corpuscle in infantile pseudo-leucæmia (Jaksch) the discovery has stimulated many to further research. It is well known that in the blood of infants nucleated red blood-corpuscles are common even in health. They are like a nucleus when at rest, round, and exhibit no property of caryocinesis. It is possible that it has this property, but it has not yet been demonstrated in healthy infants. In infantile pseudo leucæmia mitotic changes in the red blood-cells are so constant and occur in such large numbers that Luzet regarded it as characteristic for that disease, as a means of differential diagnosis from other forms of anæmia. If we have an infant with an enormously enlarged spleen, and by examination of the blood find large numbers of red blood-cells in process of caryocinesis we are justified in making a diagnosis of infantile pseudo leucæmia. But from a given specimen of blood without a clinical history the diagnosis cannot always be made, hence it is not characteristic for this disease. I base this statement from a specimen of blood taken from a case which was diagnosed as scurvy by Dr. Fuhs at St. Catharine's Hospital. The specimen showed the nucleus at rest, accessory nuclei, irregular shaped nuclei, the nucleus split in half, the rosette-shape, and large numbers in which the cells were filled with threads and dots; (chromatic corpuscles), as though the specimen had been "fixed" in Flemming's solution. The specimen was examined fresh and can be preserved as well as those which are "fixed" and stained. Askanazy recently reported a picture similar to the one described above in a case of pernicious anæmia. He saw caryocinesis and what he terms "karyolysis" (retrograde metamorphosis of the nucleus) in quite a number of the cells. In a fresh specimen he even saw different phases of caryocinesis in a single red blood-cell. The subject is in its infancy, and much may yet be demonstrated. The conclusion can be safely made that caryocinesis in the red blood-corpuscles is not characteristic for any given disease, and further research may prove it to be more common than we now regard it.

158 ROSS STREET.

infectious disease. The poison of grief is more than a name. To urge work, study, travel, the vain search for amusement, is both useless and dangerous. For a time the whole organism is overthrown, and temporary seclusion is imperative for proper readjustment.

After some bereavement the custom of wearing mourning has a distinct moral value. But its period of use must be brief: a few weeks, months, perhaps a year; otherwise dense black draperies become a burden, an æsthetic blunder, and a source of depression in themselves. For a time they have a place, securing consideration from strangers and silence from mere acquaintance, since sorrow is one of the touches of nature that makes the whole world kin.

When there is nearness of relationship to nature, rambles in the open air, days alone with the sea, alone in the forest, console as nothing else can. Quiet, silent drives, or even short journeys by rail, will reveal a new heaven and a new earth to one fatigued and worn by sorrow. Music, when it can be borne, has a soothing power beyond words. Books, too, have their place, those gentle companions without speech whose calm society helps annihilate time and space, and who always receive us with the same kindness. The familiar faces of newspapers and journals bring a stray comfort that even the tenderest heart is powerless to bestow. The care and companionship of children is another source of strength. Children are not watching to see how the afflicted are bearing up under sorrow, nor are they waiting for some expression of sentiment or the overthrow of self-control. A child is always the best comforter, uttering no word of sympathy, yet rousing interest in life because its nature is sweetness and light.

Grief cannot be ignored, neither can it be cheered up. It must be accepted, and allowed to wear itself away. Readjustment comes slowly. Sorrow, grief, and all great misfortunes should be regarded as conditions similar to acute infectious diseases, which they resemble in result; and later, as convalescence from such diseases. Seclusion, rest, sleep, appropriate food, fresh air, sunshine, interests that tax neither mind nor body, these are requirements in this class of illness. The care of the condition following depressing emotion calls for the same treatment in greater or less degree.

WATER-BAG BURNS.

It would scarcely be believed by one without subjective or objective experience in the matter that an ordinary rubber water-bag, filled with what usually passes for hot water, would be capable, when applied to the human skin, of producing an extensive and deep burn. All are familiar with this effect from the careless use of the hot water-bottle, and the surgeon seldom fails to see to it personally that a proper protection separates the glass from the skin. Conditions of shock, lowered vitality, faulty circulation, with exsanguinated and cold extremities are those in which heat is most often sought to be externally applied by this means, and it is just in these states of lessened power of resistance that the tissues are most apt to suffer. Since it is not so generally known that the rubber bag is possessed of decided powers for evil as well as for good, it may be well for the trained nurse, no less than the physician, to be reminded of it. At a recent meeting of the New York Dermatological Society the question was brought up for discussion by the report of a severe burn with deep destruction of tissue extending through the subcutaneous fat. An operation had taken place, and the water-bag had been applied to the feet while the patient was still under the anæsthetic. Several of the members present at the meeting had been consulted in similar unfortunate accidents, and as these are just the cases which sometimes cause patients to think they have grounds for legal redress, a note of warning may cause us, conscious of having done no harm ourselves, to feel beneath the covers and make sure that the nurse is allowing none to be done.

THE CURE BY FAITH.

New Jersey has ever had an enviable reputation for fair-dealing and quick justice. It is seemingly hard upon the young New York doctor when the heat of July beats down upon this side of the Hudson that he cannot freely transpose the seat of his usefulness to Asbury or Spring Lake without prolonging his journey to Trenton and his agony in a three days' strict "Exam." The justice comes in when the quack, driven from our inhospitable shore seeks to find a lodge in the vast wilderness of Jersey City Heights.

The struggle to maintain the State's medical rights, in the first place for Jersey physicians, and secondly for those who are reputable, is beginning to show signs of succeeding. An indictment has just been found against a faith-curist, who is to be tried under the new law, passed through the efforts of the State Medical Board of Examiners, making it a misdemeanor for any faith-curist or mind-healer to practise in the State.

We do not take it that the Board denies the value of faith or the great influence which may be exerted upon disease by mental processes. They have, however, started out to see to it that whoever wishes to engage in the healing of the sick must show himself to be properly qualified. Once the examination passed, the successful candidate may employ faith, hypnotism, or any other form of mind influence alone, if he and his patients prefer it to the usual way of giving it mixed with drugs.

The trial about to take place should attract some attention, being the first since the act went into effect, and it is said will be fought on the ground that it is not constitutional.

An Order of Medical Monks has been founded in this city in connection with the Episcopal Church. The object of the order is thus expounded by Father Johnson: "The text of the order," he said, "will be 'Heal the sick, and say unto them, The kingdom of God is come nigh unto them,' taken from St. Luke x. 9." The order was the idea of Mr. Davidson. It is the intention to found an order of medical monks, who will be connected strictly with the church, and who will devote their time to the poor and sick of the parish. The only compensation which the members of the order will receive will be what the parishioners can afford to give them. The members of the order will rank as deacons in the church. There are at present two novitiates, of whom one is a trained nurse, the other a medical student.

News of the Week.

Unveiling of the Sims Monument.—The ceremonies of the unveiling of the statue of Dr. J. Marion Sims will be held at 3 P M. on Saturday, October 20, 1894, in Bryant Park, New York (Forty-second Street and Sixth Avenue). Addresses will be delivered by Drs. George F. Shrady and Paul F. Mundé, after which the statue will be formally presented to the city of New York, on behalf of the medical profession of this and other countries, and will be accepted for the city by Mayor Gilroy. The medical profession and public are respectfully invited to be present.

Soon after Dr. Sims's death, in 1883, the movement for the erection of a bronze statue was set on foot by the MEDICAL RECORD, and the necessary funds were subscribed by members of the medical profession in this and other countries. American sculptors were at first asked to compete in a design for the work, and when all the designs submitted were rejected by the committee having the matter in charge, the commission for the statue was awarded to Müller, of Munich.

The House-warming of the New Bloomingdale Asylum.—The patients of Bloomingdale Asylum were recently transferred from the old site on Harlem Heights—which had been occupied for almost three-quarters of a century—to the new institution near White Plains. The removal was made by easy stages, and without unpleasant incident. The new establishment being in running order, invitations were recently issued to members of the profession likely to be interested in this line of medicine to inspect the new building. A large number of New York physicians accepted the invitation, and were shown through the institution last Wednesday afternoon, and pleasantly entertained by the officers of the Asylum. The new Bloomingdale is located just on the outskirts of the village of White Plains. The main building stands on a broad hill-top, commanding a fine inland view. It presents a very pleasing exterior, with little of the prison-like aspect that usually characterizes asylum buildings. Within, its appointments are all that intelligent study of the prominent asylum plants in the world, backed by abundant means, could make them. The building is fireproof throughout, and the utmost attention has been given to its sanitary features. It is supplied with water from springs on the Asylum property. The sewage system connects with that of the neighboring village. The Asylum has its own electric plant, ice machines, and the like. A special feature of the institution is that most of the peculiar advantages of the cottage system of architecture are secured without the sacrifice of the conveniences of the linear system. The entire main building may be said to be under one roof, inasmuch as closed corridors connect its various sections, yet these sections are, for most practical purposes, independent and detached buildings. One section of each wing has been especially constructed for hospital wards. In a word, nothing has been omitted that could help to make the new Bloomingdale strictly up to date in all its appointments, and the peer of any asylum plant in the world. The credit for its many excellencies is very largely due to the Medical Superintendent, Dr. Samuel R. Lyon, who for many years has made hospital construction a special study, and who drew the original plans for the new Bloomingdale, and directed and supervised the work of construction with unremitting energy. Whatever differences of opinion may exist as to the ideal plan for an asylum, it must be conceded by everyone that Dr. Lyon has succeeded in combining the best features of the various systems to a remarkable degree in the New Bloomingdale.

Dr. Charles H. Pinney, of Council Bluffs, Ia., died from injuries received in a railroad accident, near Lincoln, Neb., on August 9th. He was Professor of the Principles and Practice of Medicine in the Medical College of Council Bluffs. During the Civil War he served as surgeon in the Ninth Ohio Cavalry. Dr. Pinney was fifty-two years old at the time of his death.

The State of Connecticut is agitating the question of establishing a State Commission in Lunacy. "Don't."

Dr. Stuart Douglas, resident physician for the insane at Bellevue Hospital, died on October 14th, of Bright's disease. Dr. Douglas went to Alexandria, Va., about six weeks ago to attend his father's funeral, and when he returned to this city he complained of feeling ill.

Dr. Douglas was born in Alexandria thirty-three years ago. His early youth was spent at Leesburg, Va. He is a graduate of the academic and medical departments of the University of Virginia, and came to this city in 1881, taking a post-graduate course at the College of Physicians and Surgeons. He was appointed to take charge of the insane at Bellevue on October 26, 1887, and was the only salaried physician at the hospital. Dr. Douglas was a member of the Southern Society, the American Academy of Medicine, and the Society of the Alumni of Bellevue Hospital, and Instructor in Mental Diseases in the Post-Graduate Hospital. The last piece of work that he did was the writing of an article on "The Treatment of Melancholy" which appeared in the *Post-Graduate*.

Skunks and Typhoid Fever.—The skunk farm and typhoid fever epidemic are two of the unpleasant things with which the residents of Beadner, Wood County, O., are now contending.

The Decreasing Death rate.—A statement prepared by the Health Department shows that the death-rate of this city has been lower this year than since 1884, though then it was low as compared with the average of the preceding years. Moreover, the number of deaths, says *The Sun*, has been less actually than in any year since 1890, though meantime the estimated population of New York has increased by more than a quarter of a million, or from 1,705,980 in 1890 to 1,957,452 in 1894. If the mortality for the remainder of the year be the same as in the corresponding period of last year, the total for 1894 will be less than in 1893 by more than 2,500. The experience since January, and the present condition of the city as to health, indicate the probability that this is an overestimate of the mortality for October, November, and December, and that actually the total number of deaths in 1894 will be less than in 1893 by toward three thousand, or not much above the total for 1890, which was 40,103. This would make the death-rate, or the mortality proportionately to 1,000 in the population annually, about 21 in 1894, as compared with 23.51 in 1890.

Dr. John Y. McGay died on October 13th, at his home in Brooklyn, forty years of age.

Sir Joseph Lister.—It is proposed to present Sir Joseph Lister with a memorial on the occasion of his retirement from active work.

Doctors as Companions.—The following passage from Mr. James Payn's "Gleams of Memory," now appearing in the *Cornhill Magazine*, will be interesting to members of the medical profession: "Upon the whole, and for a 'scratch' companion, I prefer a doctor to a man of any other calling. He may not be very good as a conversationalist, but he is rarely very bad, like a cheroot. He has had a genuine experience of life, and has seen down to the depths of it; a sick man does not attempt to deceive his doctor, or put the best face on his character, as he does with a priest. Moreover, what is very unusual, your doctor knows more about you, professionally at all events, than you know about yourself. He does not tell you about it, it is true; not a word of that aneurism you carry about with you, and which will some day kill you in half a minute, but your consciousness that he may possess such knowledge makes him interesting. The best suggestions I have had made to me for plots for my novels have come to me from doctors, to whom I have also had cause to be grateful for many things."

The Perils of Football.—We have received from a correspondent, in reference to the fact that many serious accidents, and more than one death, have already, and thus early in the season, been reported from the football field, the following letter: "All lovers of football, both players and spectators, would rejoice if accidents due to football were of less frequent occurrence; and I feel sure that such would be the case if these suggestions were carried out: 1. Give the linesmen, as well as the referee, power to stop the play for a foul charge or hack. 2. Let the spectators desist from such cries as 'Pay him out,' etc. 3. Let the players wear tennis shoes, and not boots with steel plates inside the toes, as I know the modern boots are now made." We agree with our correspondent's first two suggestions, and go further. It has always been our cry—and we have been pleased to see it taken up and echoed approvingly by our contemporaries, medical and lay—that the strengthening of the authority of the referee, coupled with more drastic penalties for the wrongdoer, must be the most practical method of preventing accidents that arise not so much from the essential laws of the game as from "bad blood." And certainly such cries as "Pay him out" are the very things to rouse the evil spirit. Our correspondent's third suggestion is not so sensible. Firstly, nailed and steel-shod footgear is not permissible by the laws of the game; and, secondly, india-rubber soles would practically alter the game.—*The Lancet.*

The Attraction of Football for Intellectual Men.—In an article on the present state of college football, Professor E. L. Richards, of Yale, speaks of the attractions of the game for intellectual men as well as for the student of muscular science. He says, speaking of the relative attractions of football and other athletic games: "That the game has had attractions for intellectual men in the past is shown by the fact that the average scholarship of men on the football teams has of late years been higher than that of men in the other athletic organizations. In the years 1879 to 1888 the average standing of men not on athletic organizations was, on a scale of 4, 2.69; for members of the university boat crew the average was 2.52; for members of the baseball nine it was 2.41; for members of the football team it was 2.68. Track athletics were not in existence as an organization through the whole decade, but for the few years when there was a university team the average was 2.66. In the previous decade, 1869 to 1878, it is only fair to add that the average of the football men was slightly below that of the other athletes, it being 2.51 to their 2.56. I can only account for the fact of the rise of the average in the second decade by the change in the numbers of the team from twenty to eleven—a change giving opportunity for more skill, thus rendering the play more attractive to men of mind. Notwithstanding the present style of mass play, which puts a premium on physical strength and weight, it was a surprise to me to find that the average scholarship of the sixteen men from the academic department, including players and substitutes, was higher than the average of any class which ever graduated. I cannot believe, however, that the high scholarship of football players will always prevail, unless the style of the game be changed to one which admits of more open play. The present style of mass play and momentum play puts a premium on weight and brute force. The mingling men in masses make injuries more probable than in an open style of play. The mass play makes the game as little as possible a kicking game. It eliminates a great deal of the element of skill. Skill ought to be encouraged by setting some sort of premium on it. Increasing the number of points scored by a drop kick from the field might accomplish this somewhat. Some changes in the rules regarding 'interference' would do more. If, again, 'the warnings' for 'rough play' were entirely omitted, and the umpire were instructed to send a man off the field at the first offence, captains would train their men to avoid these plays entirely. Then the experts, in reforming the game, could not do better than turn their attention to the umpires. If a plan for training umpires could be devised it would be a good thing."

Philadelphia as a Medical Centre.—According to the Philadelphia newspapers that city is again asserting its right to special prominence as a medical centre. The census of the medical schools is as follows:

University of Pennsylvania,	875
Jefferson,	700
Hahnemann,	325
Medico-Chirurgical,	300
Woman's,	200
	2,400

Physical Culture in Unhealthy Schools.—There are one hundred and eighty sanitarily defective schools in Chicago, and the city spends about $4,000 annually on an athletic overstrain fad called "physical culture," whose chief purpose seems to be to provide "professional foreigners" of the ward-heeler type with an occupation. The money wasted on this "physical culture" humbug could be advantageously employed in remedying the sanitary defects of a few schools.—*Medical Standard.*

Reviews and Notices of Books.

Pain in its Neuro-pathological, Diagnostic, Medico-legal, and Neuro-therapeutic Relations. By J. Leonard Corning, A.M., M.D., Consultant in Nervous Diseases to St. Francis' Hospital, etc. Illustrated. Philadelphia: J. B. Lippincott Company. 1894.

As an aid to diagnosis in nervous disease the author considers pain unique in importance. The insomnia and melancholia induced by it are in themselves matters of serious moment. The special therapeutics of pain are given in detail and evince much conscientious research. This work is one of marked originality and careful thought. There is in it much to interest the general reader. In point of letter-press, binding, and paper, the book presents attractions that the student cannot fail to appreciate. The illustrations are clear, and add to the value of the text.

The Care and Feeding of Children. A Catechism for the Use of Mothers and Children's Nurses. By L. Emmett Holt, M.D., Professor of Diseases of Children in the New York Polyclinic, etc. New York: D. Appleton & Co. 1894.

This Catechism was originally designed for the pupils in the Practical Training School for Nursery maids, established in 1889, and compiled to meet the need felt for some simple manual. A series of questions and answers was made out, on matters of every-day practical observation and careful hospital work. The Catechism is now given to the public, with the hope that it may serve a useful purpose in other institutions, and be of value to mothers and to the ordinary untrained child's nurse. The essentials are strongly emphasized in the form of questions and answers. The first part, devoted to the care of children, treats of such subjects as bathing, eyes, skin, mouth, clothing, nursery, weight, weaning, etc. The second part deals with infant feeding. And the third is devoted to miscellaneous topics, as sleep, teething, walking alone, convulsions, colic, contagious diseases, etc. The advice given is excellent and perfectly clear, and goes over all the ground concerning which the doctor is so often questioned. If it could be followed by those who read, it is safe to say that disease in infancy would rapidly diminish and the happiness of childhood be greatly increased. Sixty-six pages of good advice are given, all for fifty cents. Less than seven inches long and about five wide, Dr. Holt's Catechism contains in most convenient form all the precepts of modern nursery orthodoxy.

Small Hospitals, Establishment and Maintenance. By A. Worcester, A.M., M.D.; and Suggestion for Hospital Architecture, with Plans for a Small Hospital, by William Atkinson, Architect. New York: John Wiley & Sons. 1894.

This is one of the subjects that at present occupies the public attention—the building and management of hospitals in small towns and villages. Dr. Worcester's book answers the questions that directly confront the promoters of such schemes for public welfare. In Part I. full directions are given for inaugurating the hospital and for arranging its management. Part II. is devoted to plans for buildings and hospital construction. While thoroughly up to date and embodying the best principles of such work, the book is not too technical for the general reader. The author realizes that much as the success of a hospital depends upon its medical and surgical staff, even more does it depend upon its nursing service. The best plan is to have the nursing service done by the student nurses of some training school, in order to secure ambitious, capable young women who are by nature fitted to undertake such work. There were no real trained nurses until some years after the war. It will be a great surprise to many to learn that in former times in Bellevue Hospital the nursing was intrusted to women who in the police courts chose a term of service as hospital nurses when the alternative of a term of imprisonment was given them! The book is earnest and well written, and the plans offer the greatest possible economy of space, together with convenience and harmony of design.

Diseases of the Skin. An Outline of the Principles and Practice of Dermatology. By Malcolm Morris, Surgeon to the Skin Department, St. Mary's Hospital, London, etc. With eight Chromo-lithographs and seventeen Wood-cuts. Philadelphia: Lea Brothers & Co. 1894.

The clearness of this book, together with its good illustrations, careful arrangement, and the practical clinical presentation of skin diseases that it gives, makes its probable destiny one of general and well merited popularity. All important schemes of classification are referred to, and that of Unna followed in the main, the author feeling convinced that whatever changes may come about in the manner of looking at diseases of the skin, increased knowledge cannot alter the principle upon which this is based. The chapters on pathology and diagnosis are remarkably interesting, the latter enunciating practical principles of definite value. Affections of the skin dependent on nerve disorder are next considered; then artificial eruptions, eczema (thirty-four pages), pityriasis, psoriasis, local inoculable diseases, general inoculable diseases, diseases of the skin-glands and epidermic appendages, new-growths, and malformations. In the matter of treatment, which is always possible and unusually practical, great stress is laid upon the care of the patient and his general condition, factors sometimes overlooked in the supervision of abnormal states apparently so definitely local as troubles with the skin. Of convenient size and easy to handle, Dr. Morris's book has everything to recommend it.

Handbook of Obstetric Nursing. By Francis W. N. Haultain, M.D., F.R.C.P. Ed.; Lecturer on Midwifery and Diseases of Women School of Medicine; Obstetric and Gynecological Physician Royal Dispensary; Examiner Royal College of Physicians, Edinburgh; and James Haig Ferguson, M.D., F.R.C.P. Ed., M.R.C.S. Eng.; Lecturer on Midwifery and Diseases of Women School of Medicine; Obstetric Physician New Town Dispensary; Examiner Royal College of Physicians; Late President Royal Medical Society, Edinburgh. Second Edition, Revised and Enlarged. With Thirty-three Wood Engravings. Philadelphia: J. B. Lippincott Company. 1894.

This is a well arranged handbook for the guidance of monthly nurses and midwives, written in clear and simple language, very neatly printed, and of convenient size. The authors are teachers who have had practical experience in the needs of obstetric nurses, and their book is one that can be recommended. The illustrations are instructive, and a good index facilitates reference.

The Jewish Method of Slaughter Compared with Other Methods, from the Humanitarian, Hygienic, and Economic Points of View. By J. A. Dembo, M.D., Physician to the Alexander Hospital, St. Petersburg; Member of the St. Petersburg Medical Society; Member of the Society for the Preservation of Public Health, etc. Translated from the German, with the Author's Amendments. London: Kegan Paul, Trench, Trübner & Co. 1894.

The basis of this book is the report of an investigation into the Jewish method of slaughtering animals, by cutting the carotids and other large vessels of the neck, undertaken at the instance of the Russian Societies for the Prevention of Cruelty to Animals. The author believes that such a method, used to-day we believe in New York, inflicts a minimum of suffering upon the animals, produces whiter and firmer meat, and, from the point of

view of the purchaser, is the more economical. His argument is well sustained, and certainly seems to prove his point.

INEBRIETY OR NARCOMANIA. Its Etiology, Pathology, Treatment, and Jurisprudence. By NORMAN KERR, M.D., F.L.S.; Fellow of the Medical Society of London; President Society for the Study of Inebriety; Chairman British Medical Association Inebriates Legislative Committee; Consulting Physician Dalrymple Home for the Treatment of Inebriety; Vice-President International Congress of Medical Jurisprudence; Corresponding Member Medico-legal Society of New York; Corresponding Secretary American Association for the Study and Cure of Inebriety. Third Edition. London: H. K. Lewis. 1894.

THIS book is well known, through its earlier editions, to the large and increasing number of medical practitioners who recognize in inebriety a disease, and not a vice, in the common acceptance of the word, worthy of the same serious study as any other physical or mental malady, and one that is, in many instances, amenable to cure through the institution of rational scientific treatment. By the term inebriety is not meant simply an over-indulgence in alcoholic liquors; the word is employed as an inclusive term for all forms of drug addiction, narcomania, the particular kind of intoxicant employed being accidental, determined by environment or other conditions. The author defines the word as meaning "a constitutional disease of the nervous system characterized by a very strong morbid impulse to, or crave for, intoxicants." Most inebriates long for alcohol because that is among us the narcotic in common use. The present edition of the work contains a large amount of matter not found in the former editions, including a study of ether addiction, at one time very common in Ireland; a dissertation on the place of alcohol in therapeutics; on the relation of insurance to inebriety, and on the criminal responsibility of inebriates. The book is interesting apart from the valuable lessons which it teaches, and we can thoroughly recommend it as a safe guide to this most important branch of medical science. The presswork is all that could be desired, and a complete index makes it a valuable work of reference.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE, DESIGNED FOR THE USE OF STUDENTS AND PRACTITIONERS. By AUSTIN FLINT, M.D., LL.D., late Professor of Principles and Practice of Medicine, Bellevue Hospital Medical College, New York. Seventh edition. Thoroughly revised by FREDERICK P. HENRY, A.M., M.D., Professor of Principles and Practice of Medicine, Woman's Medical College of Pennsylvania. 8vo, pp. 1,143. Philadelphia: Lea Brothers & Co. 1894.

To the old students of the late Professor Flint this new edition of his classic work will be most welcome. Its peculiar excellences and its breadth of conception have made it a recognized authority from the time its first edition appeared. The author was a born teacher, an indefatigable observer, a painstaking worker, and a thorough medical philosopher. His clinical pictures of disease are models of graphic description, minuteness of detail, and breadth of treatment. To such as will see the work for the first time there is an agreeable surprise in waiting. This may appear to be high praise, but the work has so well earned its leading place in medical literature that but one view can be expressed concerning its general character as a text-book. The editor has done his part in bringing it up to date, not only in reference to treatment and the adaptation of the newer remedies, but has made numerous additions in the shape of the newly discovered forms of disease, and has elaborated much in the commoner forms which the recent advances have made necessary. Among the new articles are those on Pulsating Pleurisy, Hereditary Chorea, Weil's Disease, Syringomyelia, Acromegaly, Raynaud's Disease, Anthrax, and Glanders. The section on General Pathology has been omitted, as in its old form it was obsolete, and its spirit could hardly be maintained in any reconstructed form as would consistently adapt itself to progress made since it was first written. The classifications have been retained, but some of the articles, such for instance as dyspepsia, indicating a series of functional disturbances, have been treated under the different and now well recognized pathological conditions.

Although the doctrine of self-limitation of diseases so well advocated by Dr. Flint still stands prominently forth in the admirable natural histories he gives, the element of treatment is by no means neglected, in fact by the editor a fresh stimulus is given to this necessary department by a comprehensive study of all the new and leading therapeutic agents.

ASEPTIC SURGICAL TECHNIQUE. With Especial Reference to Gynecological Operations. By HUNTER ROBB, M.D., Associate in Gynecology Johns Hopkins University. 12mo, pp. 264. Philadelphia: J. B. Lippincott Company. 1894.

THE author of this little book goes into the subject of asepsis not only from a bacteriological but from a surgical point of view, and happily combines the functions of each in making what may practically and theoretically constitute the ideal operator. His treatment of the subject is thorough and fully abreast with the latest bacteriological principles of wound treatment, and upsets many of the cherished notions of wound irrigation by bichloride, carbolic solutions, and the like. The careful descriptions of the most approved methods of asepsis by sterilization of instruments, clothing, and dressings, and the insistence of the elaborate ablutions of the hands as practised at Johns Hopkins will impress the reader with a minutia of detail which is fully in keeping with the importance of doing the little things well in order to insure the success of the greater. The work is practical from first to last, and cannot fail to give the reader all the really necessary information required for the practice of asepsis in all the varied gynecological operations. The illustrations are numerous and well executed, particularly the plate which forms the frontispiece, and gives the different pathogenic microbes.

TEXT-BOOK OF ABDOMINAL SURGERY. A Clinical Manual for Practitioners and Students. By SKENE KEITH, F.R.C.S. Ed., Assisted by GEORGE E. KEITH, M.B.C.M. 8vo, pp. 508. Philadelphia: J. B. Lippincott Company. 1894.

ABDOMINAL surgery has grown since 1880 into such a recognized speciality, that any work claiming to be a systematic account of its present status and its future possibilities will be warmly welcomed by progressive operators. Considering the amount of literature upon the subject, the authors have experienced no small amount of difficulty in summarizing results and in reconciling the widely varied views of investigators in this prolific field. But the work, on the whole, has been well done, and stands as a model of its kind for clearness of description, reasonable minuteness of detail, and soundness of surgical principle. Many of the supposed difficulties are simplified in a way that is inviting to the student and assuring to the practitioner. Altogether, it shows the present state of our knowledge of abdominal surgery and creditably covers the entire field, treating systematically of the various diseases of the different organs below the diaphragm.

The first section comprises the surgery of the abdomen from the standpoint of the general operator, while the second section treats of the department of operative gynecology. Under the former are described the diseases of the stomach, intestine, appendix, liver, kidney, and spleen, which may call for surgical treatment; while under the latter are discussed ovariotomy, diseases of the ovaries and Fallopian tubes, uterine fibroids, and diseases of the uterus generally. Each one of the various operations are described in sufficient detail, and all the neces-

sary directions given for after treatment. Aseptic precautions are consistently advocated, and many very valuable practical suggestions are offered for emergencies away from hospitals and in remote rural districts. The technique of the different operations is very satisfactorily explained, as well as the methods of diagnosis and the fundamental principles of after treatment. This is especially manifest in the discussion of intestinal lesions, the choice of operations, and the cardinal symptoms upon which a diagnosis is founded. The bugbear of intestinal approximation is robbed of much of its perplexities and difficulties by the description of the simple and effective methods of the authors. In intestinal anastomosis Senn's plates are uniformly advised, but, strange to say, nowhere is even an allusion made to the Murphy button. Much stress is laid upon electrolysis in the treatment of uterine fibroids, which is good in its way, as offsetting the fashionable, formidable, venturesome, and unsurgical proceeding of hysterectomy in such cases. The book as a whole is a valuable clinical contribution, and is destined to become authoritative on all principles upon which the abdominal surgery of to-day is founded.

History, Constitution and By-laws, and List of Members of the Society of Alumni of Bellevue Hospital. New York: De Vinne Press. 1894.

We learn from this little book that the Society of Alumni of Bellevue Hospital of this city is in a very prosperous condition. Its membership now numbers one hundred and ninety-nine.

The American Institute of Homœopathy. Section of Materia Medica and General Therapeutics.

This is a report of the meeting of the Therapeutic Section of the American Institute of Homœopathy, held in Denver in 1894. The proceedings consisted chiefly in the discussion of the subject of how to treat and how to learn materia medica. The little book contains numerous half-tone portraits of many of the leading homœopathic practitioners in this country and England.

Macrobiotic, or Our Diseases and Our Remedies. For Practical Physicians and People of Culture. By Julius Hensel, Physiological Chemist. Translated by Professor Louis H. Tafel, of Urbana University, O., from the Second Revised German Edition. Philadelphia. Boericke & Tafel.

The author of this book attributes diseases to a diminished electric force, and proposes to prevent and cure most ills by his "physiological salt water." His notions of pathology are interesting. Diphtheria, which he calls "children's catarrh," begins, he says, "with stagnation of the blood in the thymus gland, whence the products of the putrefaction of the albumin of the blood are spread with their infecting force over the whole vascular system." The views set forth in other portions of the book are equally sound and scientific.

Transactions of the South Carolina Medical Association. Forty-fourth Annual Meeting, held in Rock Hill, S. C., April 25 and 26, 1894. Charleston: Walker, Evans & Cogswell Co. 1894.

This volume of the Transactions for 1894 contains the minutes of the meeting and the usual number of papers, reports on special subjects, etc. The next meeting of the Association will take place in Columbia on the fourth Wednesday in April, 1895.

Précis de Clinique Thérapeutique. Par le Dr. A. F. Plicque, Ancien Interne des Hôpitaux de Paris, Lauréat de la Faculté de Médecine, Lauréat des Hôpitaux. Paris: G. Steinheil. 1894.

The author of this little work says that it had its origin in notes made for his own use during the early years of practice. He found, in beginning his life-work, that the conditions of private practice were very different from those of hospital practice, and required often the exercise of certain faculties and of a kind of knowledge not gained in institution life. The work cannot pretend to the dignity of a system of medicine, being, as its name implies, simply a manual of therapeutics. But it is a good manual, systematically arranged, and written in a lucid style; the directions are simple, and the reader is not bewildered by a long catalogue of drugs for every disease. Under each heading the indications for treatment are briefly stated, and then the author mentions a few of the best and tried remedies and gives directions for their employment. The book deals with internal medicine only, and does not touch upon surgical, venereal, or cutaneous disorders.

A Handbook of Medical Microscopy for Students and General Practitioners, Including Chapters on Bacteriology, Neoplasms, and Urinary Examinations. By James E. Reeves, M.D., Member of the Association of American Physicians; Ex-President of the American Public Health Association, etc. Philadelphia: P. Blakiston, Son & Co. 1894.

The author of this excellent little manual states in his preface that his object in writing the book was to take away from the practising physician all excuse for his neglect of the microscope in his daily work. He says, and very justly, that the time has now come when all progressive physicians and surgeons, general practitioners and specialists alike, must either themselves possess sufficient skill in microscopic technique for the faithful and proper discharge of the high obligation which rests upon them in the diagnosis and treatment of diseases, or else be able to command the ready service of some accomplished microscopist and pathologist to do such necessary work for them. The writer himself is a general practitioner belonging to the former class, knowing by actual experience the needs of those situated like himself, and has the rare gift of being able to impart this self-acquired knowledge to others. The work is not elementary for the professional microscopist, but it is admirably adapted to meet the work of the general practitioner, for whom it was written.

Memoirs of the Boston Society of Natural History: Volume IV., Number XI. A Bibliography of Vertebrate Embryology. By Charles Sedgwick Minot. Boston. 1893.

This bibliography appears to be a most exhaustive one, containing 3,083 titles, all of which the author states have been verified in the libraries of Boston and Cambridge, or in that of the Surgeon-General's Office in Washington.

Gynäcologische Anatomie. Die Geschwülste der Eierstöcke. Von Dr. C. H. Stratz. Berlin: H. Kornfeld. 1894.

This beautiful atlas of ovarian tumors consists of fourteen colored plates, with fifty figures, delineating a great variety of tumors of the ovary. The author has had a vast amount of material to select from in Schweder's Clinic, in the Frauenklinik of Berlin, and during his own five years' practice in Java. He appears to have made judicious use of this material, producing an atlas not only of rare tumors, but also of those most commonly met with in everyday practice. There are some forty pages of descriptive text. The plates are well executed and printed, and the work does credit to author and publisher alike.

Human Physiology. By John Thornton, M.A., Author of Elementary Physiography, Advanced Physiography, etc. With 268 Illustrations. New York: Longmans, Green & Co. 1894.

All the essential facts of human physiology have been brought together in this handy manual of some 450 pages, in a form convenient not only for continuous study, but also for occasional reference. The author's style is as easy and smooth as his descriptions are lucid. The illustrations, some of them colored, are numerous and well executed. To the general practitioner, who is not a special student of physiology, we can recommend this little work as one which will satisfactorily meet his needs in this branch of science.

VADE-MECUM du PRATICIEN. Diagnostic et Traitement des Maladies Internes. Par le DR. FERNAND ROUX. Paris: G. Steinheil. 1894.

THIS is a useful manual, giving the main points in the diagnosis and treatment of non surgical diseases. The subjects are arranged alphabetically, convenient for ready reference, and the therapeutic suggestions are for the most part sound, and in accordance with the latest discoveries in this branch.

TRANSACTIONS OF THE AMERICAN GYNECOLOGICAL SOCIETY. Vol. XIX. For the year 1894. 8vo, pp. 363. Philadelphia: W. J. Dornan. 1894.

THIS valuable volume contains several admirable papers on hysterectomy, others on face presentations, and a masterly address by the President, Prof. Lusk, on the relative value of the various methods of treating uterine fibroids.

SHARP'S TRACTS ON HOMŒOPATHY. 14th Thousand. 8vo, pp. 232. Philadelphia: Boericke & Tafel. 1894.

THIS is a collection of tracts intended for the defence of Homœopathy, the theory of small dosage, the value of the so-called provings, the advantage of single doses, and the general advantages of the system. To such as are interested in the subject this little book will furnish much food for reflection.

A TREATISE ON APPENDICITIS. By GEORGE R. FOWLER, M.D., Examiner in Surgery, Surgeon to St. Mary's and Methodist Episcopal Hospitals, Brooklyn. 8vo, pp. 190. Philadelphia: J. B. Lippincott Co. 1894.

THE present compact treatise comes at an opportune time for the discussion of many questions bearing upon the etiology, pathology, and surgical treatment of an interesting and very frequent surgical disease. The exceptional opportunities for observation which the practice of the author has given him are utilized in a practical and intelligent manner for the benefit of his many readers. Many of the mooted points in the pathology of the affection are discussed with becoming candor and independence, and with a thoroughness eminently commendable. Especially interesting are the views regarding the etiology of the disease as bearing directly and almost solely upon microbic influences. The clinical reports which are inserted in the text are typical of their kind, and serve their full intention of pointing questions of pathology or illustrating lines of treatment. The operative technique is very fully given, and the author's methods are very intelligently described. The illustrations are numerous and good, and the work altogether is a great success.

AN ILLUSTRATED DICTIONARY OF MEDICINE, BIOLOGY, AND ALLIED SCIENCES, Including the Pronunciation, Accentuation, Derivation and Definition of the Terms used in Medicine, Anatomy, Surgery, Obstetrics, Gynecology, Therapeutics, Materia Medica, Pathology, Dermatology, Pediatrics, Ophthalmology, Otology, Laryngology, Physiology, Neurology, Histology, Toxicology, Dietetics, Legal Medicine, Psychology, Climatology, etc., etc., and the various Sciences closely related to Medicine, such as Bacteriology, Parasitology, Microscopy, Botany, Zoölogy, Dentistry, Pharmacy, Chemistry, Hygiene, Electricity, Veterinary Medicine, etc. By GEORGE M. GOULD, A.M., M.D., author of "The Student's Medical Dictionary," "Twelve Thousand Medical Words Pronounced and Defined," "The Meaning of the Method of Life," Editor of the *Medical News*, etc. Based upon recent scientific literature. Philadelphia: P. Blakiston, Son & Co. 1894.

THIS in many respects admirable work possesses a great advantage over some of its recent competitors in that it is in but one volume, and therefore much more convenient as a work of constant reference. A commendable feature is the grouping together of many correlated facts in tables, of which there are one hundred and ten in all. The type employed is of excellent size, the printing is unusually good, and the illustrations are judiciously selected and not too numerous. The spelling adopted by the editor is in the direction of the phonetic, the diphthongs being dropped from words of Latin or Greek derivation, as also the final *e* of the name of alkaloids and of certain other words, such as iodide, bromide, iodine and the like, which Dr. Gould, following the suggestion of the American Association for the Advancement of Science, writes iodid, bromid, iodin, etc. In some of the words of this class the alternative spelling is given, and in others, without any apparent reason for the omission, it is not. The weakest part of the book is in the matter of pronunciation. It is very well for a medical lexicographer not to be too dogmatic in cases in which orthoepists themselves are not in accord, but his diffidence should not go to the length of sanctioning such errors as al'bumin, ab'domen, anē'mic diabē'tic, asthē'nia, synē'chia, or such wretched cacophony as making the final syllable of cocaine or leucomaine rhyme with cane or mane. In the case of some words which are frequently mispronounced, as the second one of the term diabetes mellitus for example, the author gives no sign to guide the would be orthoepist; and the pronunciation of the genitive or plural of several Latin words, such as cervix and paries, over which even well educated people so often stumble, is not given at all as far as we have been able to discover. These are sins which some may consider as venial, but we cannot so regard them. They do not absolutely destroy the value of the book as a work of reference, it is true, but they mar its perfection. A dictionary should be an authority in matters of derivation, spelling, punctuation and definition, and errors in any one of these cardinal points are unpardonable. A dictionary maker should be in these matters dogmatic, and being dogmatic should be above all things accurate, otherwise it is but a case of the blind leading the blind. We have nothing but praise for the definitions, which are clear and concise, or for the derivations, but the spelling is peculiar and in many cases unsupported by the best authorities, even by Whitney, whose phonetic tendencies were so pronounced; and as regards pronunciation Dr. Gould is, as we have said, uncertain and in not a few instances unsound. The author is already well known as a maker of dictionaries, and we had hoped that this, his latest work and the fruit of his ripe experience, would prove to be the ideal lexicon for the busy medical man. This, unfortunately, it is not, but it comes very near to it, perhaps as near as anything human can come to perfectibility.

TEXT-BOOK OF MEDICAL AND PHARMACEUTICAL CHEMISTRY. By E. H. BARTLEY, B.S., M.D. Third edition, revised and enlarged. With 84 illustrations. Philadelphia: P. Blakiston, Son & Co 1894.

THIS excellent book contains, in the most concise form, all the knowledge of medical and pharmaceutical chemistry. The present edition has been greatly enlarged, and a new chapter on Physiological and Clinical Chemistry has been added; the same deals with the chemistry of nutrition, digestion, and the urine. This chapter is treated in the most practical way, giving the principles of feeding and diet, the clinical examination of stomach digestion for diagnostic purposes, the easier methods for the examination of milk, and a fairly complete guide to the clinical examination of urine and urinary calculi. In perusing the tests for sugar we miss those of Roberts and Einhorn. The whole book reads admirably well, and deserves the highest recommendation.

DIAGNOSTIK UND THERAPIE DER MAGENKRANKHEITEN. Von DR. T. BOAS. I. Theil, 3te Auflage. Leipzig: Verlag von Thieme. 1894.

THE present edition of this so well-known book on diseases of the stomach has been greatly enlarged and contains the newest ideas and inventions in this field of medicine. Boas has given his personal experiences on many pathological anatomical conditions of the gastric mucosa, illustrating them with figures of the corresponding microscopic specimens. As to the early recognition

of cancer of the stomach he puts most stress on the presence of lactic acid in the stomach contents, this being much more characteristic than the absence of free hydrochloric acid. The book will be read with much profit by every practitioner.

Transactions of the Association of American Physicians. Ninth Session. 1894.

This volume contains an unusual amount of interesting material, and covers a wide range of medical subjects. The papers are short and practical, and for the most part bear upon the leading medical questions of the day.

Text-book of Practical Therapeutics. By Hobart Amory Hare, M.D., B.Sc., Professor of Therapeutics and Materia Medica, Jefferson Medical College, Philadelphia. Fourth edition. 8vo, pp. 740. Philadelphia: Lea Brothers & Co. 1894.

The fact that the fourth edition of this work has appeared within four years attests its value to the general practitioner, and its appreciation by the medical student. Its wide application to the practical needs of everyday medicine commended it from the first to the progressive and working therapeutist. It is not only knowing what to give, but when and where to give, and how the drug will act in given conditions, that makes one a scientific practitioner rather than an ignorant empiric. The book in such respects supplies every need. It is divided into four parts: I. General Therapeutical Considerations. II. Drugs and their Properties. III. Remedial Measures other than Drugs, Foods for the Sick. IV. The Therapeutics of Different Diseases, Tables of Doses, an Index of Drugs and Remedial Measures, and an Index of Diseases and Remedies. The author is well known as a progressive therapeutist, and it goes without saying that all the new or valuable drugs receive their full share of attention, and it is a great deal to say in this, as with other features, that the book is up to date in everything pertaining to the practical therapeutical needs of the practitioner. The additions made are articles on Methylene blue, Chloralose, Pyrogallol, Condurango, Convallaria, Duboisine, Hypodermoclysis, Enteroclysis, Lavage, and several additions to the department of individual diseases. The work has also been revised in such a way as to make it uniform with the United States Pharmacopœia.

Wann Dürfen Gonorrheische Heirathen? Von Dr. Edmund Saalfeld. Berlin: H. Kornfeld. 1894.

This is a little brochure dealing with the subject of the marriage of men who have had gonorrhœa. The author believes that the disease is curable and that when it is once actually cured the man may marry with perfect safety to his wife, himself, and their offspring, if any.

Der Alkohol als Gunss- und Arzneimittel. Von Dr. A. Jaquet, Privatdocent für experim. Pharmakologie. Basel: Benno Schwabe. 1894.

An interesting and well-considered lecture upon alcohol as a beverage and as a therapeutic agent. The author's views are very moderate, and he believes that the consumption of alcohol in the so-called physiological doses by adults is not prejudicial to health or to a long life.

A Manual of Hygiene. By Marv Taylor Bissell, M.D., Professor of Hygiene in the Woman's Medical College of the New York Infirmary for Women and Children. New York: The Baker & Taylor Company.

Dr. Bissell has done a good work in preparing this student's text-book on hygiene. Most works on hygiene are of such size and deal with the subject so elaborately that the student is repelled, being unable, indeed, to give the time necessary for the study of such a formidable looking work. In this book, which is, however, by no means a superficial one, the essentials of the science only are given, and the reader's attention is not distracted by details of value only to the specialist. The book will be found serviceable, moreover, to many practitioners as well as to students.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 4, 1894.

D. B. St. John Roosa, M.D., President, in the Chair.

The Stack Room Completed.—Dr. E. H. Grandin, chairman of the Library Committee, stated that the stack room had been completed during the summer and was now the best in the country, not excepting that at Washington. It had a capacity of two hundred and fifty thousand volumes, just five times as many as were now in the library. He made a strong appeal for books from the overflowing libraries of members, and for donations from their wealthy clientele. The library was greatly in need of an endowment fund of at least one hundred thousand dollars. Money expended in this direction would prove of far greater benefit to the public than if it were used to build more hospitals and dispensaries.

Credit was given by Dr. Grandin to Drs. A. Jacobi and A. M. Jacobus for careful supervision of the work done in the stack room. Dr. Jacobi, who arrived later, attributed all honor for the same service to Drs. Grandin and Jacobus.

The President emphasized Dr. Grandin's remarks regarding the needs of the library, and expressed the belief that if what was wanted were asked for, it would be given. New York was ever ready to give for any worthy purpose when made to appreciate its value and want, but the medical profession had been too modest, and the community had come to regard their services as consisting only in the administration of drugs and the use of the knife. High and above all else was our duty as citizens of this great nation.

Report of Committee to Constitutional Convention.—Dr. W. R. Pryor, one of the members of this committee, made a preliminary report. The committee had been received with courtesy, and, to a large extent, its suggestions had been acted upon. The Convention had agreed to abolish coroners, but refused to put doctors in their place; the Board of Regents had been incorporated into the constitution, as desired by the committee, but their objection to its being made a life tenure office had not been heeded. The committee's recommendation to make county instead of state office of charities and correction in the counties of New York and Kings, and thereby rendering the officers liable to removal by the Governor, had not been accepted, as it affected too many official heads.

Climate in Therapeutics.—The President, in introducing the author, Dr. C. Fayette Taylor, said he was sure the Academy would be glad to know the conclusions arrived at upon this subject by one who had had much experience through travel and the reliability of whose judgment had been demonstrated by enviable success in another department of medicine, that of orthopedics.

Dr. Taylor said that his object in writing the paper was to strongly impress the necessity for the profession, in recommending a change of climate, to have a definite purpose in doing so and more accurate knowledge of the qualities and health influence of the particular climate named. Some gave very indefinite advice, such as to go to California, a State which was seven hundred and seventy miles long, and embraced at least seven different climates. The mean temperature of a locality meant nothing. It might be the same in climates of greatest extremes in their influence on the health. The mean temperature in the different climates of California was nearly the same, while the extremes varied greatly, as did also the physiological effects. Moisture was a very important factor. Yet, although it favored growth of micro-organisms, it did not follow that an air dry enough to be almost free from germs was necessarily healthier. Physicians had found it necessary to send their patients, especially women

and children, living in the dry, high air of the eastern slope of the Rocky Mountains, to the moister valleys occasionally, in order to avoid nervousness and loss of flesh. He could not say whether the peculiar influence of such air was due to increased action of the heart or the constant hammering at the nerves by the wind and sunshine. The author's conclusion on this point was that, while it was important to live in an atmosphere as free from germs as possible, it was even more important to live in one which would give vigor to resist germ influence. It seemed that heretofore the study of climatology had been for the purpose of finding a place where consumptives would not die. There was no such place. There was no place where bacilli would not get in their deadly work. A question of wider interest was, what climate was best and in which we might spend the greater part of our lives? There were many other diseases of which men died besides tuberculosis. Moreover, ill health often depended upon conditions and habits quite independent of climate, and such as could be corrected without change of place. A friend in New York had been almost rejuvenated in three months by limiting his diet during that time to oysters, fish, and clam broth. People went abroad and were sent abroad by physicians in order, as it was stated, to tone up. Yet in many instances the first step toward toning up should consist in toning down. By that the author meant to reduce the unnecessary expenditure of energy which had become a fixed habit of life. Most of us were too prodigal with our resources and squandered more than the occasion required. One wisely answered, when asked how he succeeded in always being so healthy, "Be comfortable." We should learn to sit down and be comfortable where we are.

Among the countries of whose climate the author spoke from personal experience were California, Nevada, other Western and also Southern sections of this country, the West Indies, Spain, etc. He thought a visit to the tropics from time to time would prove healthful in inducing habits of reposefulness. Tropical heat was not oppressive, as was generally supposed by those who had not tried it. Wakefulness in the tropics was a rarity, while the relief obtained from nervous tension and irritability was delightful. The increased activity of the skin freed the system of morbid material and gave rest to the kidneys and lungs. It was a delusion born of the constant assertion of advocates of negro slavery before the Rebellion to suppose that white people could not work in the tropics. The Windward Islands were more favorable for health than the Greater Antilles, being too small to give rise to a land breeze and consequent impurity of air and change of temperature. A visit to tropical points should be accompanied by a change of food. One should live largely on native fruits. Hardly a better climate could be selected than the southern part of Spain, but one had to contend with lack of sanitary arrangements in the cities. The author stated that people from the South could stand northern winters better than those from the North could stand the same season in the warmer climates, and thought the explanation lay in the fact that the former had not previously expended their vital reserve in resisting cold. In visiting mineral springs one should place himself under the care of a local physician, and not ask, as many did, advice of the hotel porter.

Finally, there was an abundance of climate in our own homes if we would but open the windows and let it into our living apartments, taking due precaution against draughts and cold. Too many were taken away for a change of climate in the last stage of disease to localities where they were deprived of comforts which could only be had at home, and were brought back in a long box by a baggage car.

Dr. Simon Baruch opened the discussion. For some years past he had tried to simplify all problems in therapeutics and reduce them to first principles, as it was only in this manner that we could succeed in combating disease. It seemed to him climatology was now in the position occupied by antiseptic surgery some years ago, when it was customary to surcharge the air of the operation-room with carbolized spray, while the surgeon's finger-nails were left unclean. He was in agreement with the paper, the most important point in which, he thought, was the reference to climatic advantages of our own homes, and our failure to utilize them. As an example of what might be done, he mentioned the case of a man with phthisis who was benefited by a visit to Minnesota, which was advised by Dr. Loomis; but his cough, hectic, and loss of flesh returned on leaving those parts, and he consulted Dr. Baruch with regard to another locality. Dr. Baruch told him to remain in New York, and arranged his rooms so that he practically lived in open air and sunshine during the winter months, with the result that in two months he gained twelve pounds in weight, and lost his hectic and cough.

Three Principal Questions in Changing Residence.—Dr. R. C. M. Page thought that in considering a change of residence we were met by three principal questions at the outset: 1, The nature of the climate in its widest sense, including elevation, extremes of temperature rather than the mean, soil, drainage, winds, dust; 2, accessibility, hotel and other accommodations; 3, condition of the patient.

He believed that in the majority of cases it was the change, in a general sense, rather than the particular climate to which benefit was chiefly due. Certainly, however, some places were to be avoided on account of adverse climatic conditions, particularly by patients with phthisis. A long, continuous, tiresome journey and sudden change of altitude were now guarded against in Europe. Persons who were too sick to take exercise should stay at home among friends.

Would Establish a Sanitarium for the Poor.—Dr. Achilles Rose said that inasmuch as reference had been made to Detweiler's establishment for consumptives in Europe, he would point out the need of some similar resort in this country where those could go with moderate means and receive all the advantages of a well regulated sanitarium. The locality should be accessible to the great cities along the Atlantic coast, should be between 1,500 and 5,000 feet above the sea-level, and more south.

Dr. Sell, who had travelled a great deal and for a number of years, cautioned against sending patients to a place whose only recommendation might be its favorable climate. The general advice to go to Egypt was like sending one to California, without mentioning the particular part. He mentioned a number of places where consumptives had had a cessation of their symptoms and lived in health, but they were compelled to stay there and not return to their place of nativity. Among these was a place in Mexico, another in Texas, a third in California. There ought to be a teacher in climatology in every medical school throughout the country.

Working up a Practice.—The following advertisement appeared recently in an English lay journal: "Skin Disease.—A Specialist, who cures every description of Skin Disease, will give a liberal commission to ladies and gentlemen who will introduce patients. Every information given by addressing Specialist."

The Cholera appears, from the cable reports, to be subsiding in Europe. It still prevails to a considerable extent in St. Petersburg, Moscow, and Warsaw, and the surrounding districts, but is rapidly diminishing in Galicia and other infected provinces in the Austrian dominions. Twelve of these districts have been entirely free since the middle of September. A despatch to the State Department from Constantinople announces a renewed outbreak of cholera in that city and the outlying districts. From Hamburg is reported the death of Dr. Oertel, Assistant Superintendent of the Hygienic Institute in that place. His death occurred from cholera contracted in the course of some experiments which he was making with cultures of the comma bacillus.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, September 24, 1894.

H. D. CHAPIN, M.D., IN THE CHAIR.

Nominations.—The following nominations were made, the election to take place at the October meeting: For *President*, Drs. H. D. Chapin, E. H. Grandin, Robert Abbe, V. P. Gibney; *First Vice President*, Drs R. Van Santvoord, H. E. Crampton, A. Caillé, Wendell Phillips; *Second Vice-President*, Dr. S. H. Dessau; *Secretary*, Dr. C. H. Avery; *Assistant Secretary*, Dr. W. H. Ballard; *Treasurer*, Dr. John S. Warren; *Censors*, Drs. Seneca D. Powell, Simon Baruch, C. L. Gibson, George T. Jackson, E. D. Fisher, R. W. Wilcox, A. M. Jacobus, E. N. Liell, Charles H. Knight, William Stevens, C. C. Rice.

Nervous Dyspepsia.—DR. HENRY ILLOWAY read the first paper of the evening. Much literature had appeared under the title "Nervous Dyspepsia," but analysis showed that it was a jumble of many morbid states. The author's purpose was to justify the classification and to define the cases which properly belonged in it. The views of German writers were cited, and disapproval was expressed of including the cases under discussion under the term neurasthenia gastrica. Neurasthenia had come to be a well-established morbid entity, with certain characteristic symptoms, and where a dyspepsia was dependent thereon it could be made to disappear with special attention to the stomach itself. Nervous dyspepsia had been appropriately defined as an ailment of the stomach without any definite and fixed pathological or anatomico-pathological characteristics, depending solely upon the nerves of the stomach. The stomach is primarily affected. If any symptoms on the part of the general nervous system present themselves they are the consequence of irritation proceeding from the stomach, and therefore only secondary manifestations. Treatment must be directed to the stomach; only in that way can the disease be cured.

Symptoms.—The tongue in the morning is covered with a thin transparent coat, the red being visible through it; the patient complains of lack of hunger, but when he begins to eat he can eat as much as anybody, but when he stops his misery begins. He complains of feeling bad at the stomach, of a feeling of heaviness and distention, of eructations of gas, which, however, are attended by some relief and differing from hysterical eructation in not being continuous. The most unpleasant feeling is the one described as general irritability; a desire to have a row with somebody. There might be a feeling of pressure and irritability of the brain. Such feelings lasted an hour and a half usually, sometimes three hours, and were renewed after the next meal. The bowels were usually undisturbed, although an inactive life might lead to constipation. The patients were incapable of prolonged work, and preferred light literature. Sleep was usually undisturbed. Alcoholic beverages were not well tolerated, although frequently prescribed by physicians.

Etiology.—There were two chief causes — mental shock and tobacco smoking. Where mental shock was the cause, as loss of friends or of property, the whole force of the blow seemed to be expended upon the stomach and not upon the general system, as in neurasthenia depending upon a like cause. Where tobacco-smoking was the exciting factor the symptoms would come on after the use of perhaps a single cigar, and were not due to excessive indulgence and poisoning of the system thereby. The patients could digest nitrogeneous foods well, and usually there was a sufficient amount of hydrochloric acid and pepsin in the gastric secretions. In the author's experience there had been no atony of the stomach, yet the symptoms seemed to point to inhibition of muscular action in that organ and disappearance of the same when action was re-established. The vagus supplying the stomach seemed to be in a state of hyper-excitability, and the irritability might be so great as to cause most of the food to be rejected as soon as taken.

In differential diagnosis the author thought it only necessary to exclude neurasthenia gastrica, and this he believed not to be a difficult matter. In this affection the patient felt bad when the stomach was empty, and after eating felt much stronger and better, while the reverse was true in nervous dyspepsia. In nervous dyspepsia the food tasted good, while in neurasthenia gastrica there was no desire to eat. In the latter the intestines were affected, they were not in the former. Neurasthenic patients awoke frequently, complained of sensations of hot and cold, and sometimes as if suffering from malaria, differing in these regards from patients troubled with nervous dyspepsia.

Many had said the prognosis was unfavorable, but the author had found it quite favorable. Even cases of nervous dyspepsia of long standing would recover under proper methods. He had seen no sequelæ although he suspected the condition might in time lead to melancholia and insanity. Nor had there been complications except a slight eczema on the chin. The treatment was not considered in this paper.

A Brief Study of the Physiological Epochs that Predispose to Insanity, with Observations on the Management of Each.—DR. WILLIAM P. SPRATLING, in a paper with this title, spoke of six epochs predisposing to insanity, all of which were physiological except one, namely, heredity. In the order named they were—the epoch of childhood, of puberty, of maternity, heredity, the menopause, and senility.

The peculiarity of the epoch of heredity was its variability, embracing the period when ancestors who were inclined to insanity exhibited signs of the disease. The last epoch, or that of senility, was pathological rather than physiological.

Regarding the first epoch, Gowers had stated that one-eighth of all cases of epilepsy, which not infrequently led to insanity, began during the first three years, and with rickets as a combined cause, seventy-five per cent. were due to infantile convulsions ascribed to teething. Genuine epilepsy, however, probably never arose from dentition, but the convulsions occurring at this time might finally take on all the characteristics of epilepsy. Anything which interfered with the nutrition of the child's brain was a serious matter, for this organ acquired its chief growth the first seven years. Besides dentition as a starting cause, he mentioned blows, fevers, and other conditions which changed the physiological processes of childhood into pathological, and thus laid the basis for insanity.

Pubescence, from the fifteenth to the twenty second year, was more dangerous to the female than to the male. In the former the change from childhood was almost at a bound, while in the latter it was very gradual. The female was liable to show melancholia, mental enfeeblement, bodily inactivity, later along systematized delusion which pertained chiefly to self. The prognosis was good when there was no history of hereditary taint. Nourishment should be given in an easily assimilable form, and the secretory and excretory functions should receive particular attention as they were inclined to be sluggish. Give hypnotics or sedatives only when urgently needed. The best form of iron for the anæmia was the carbonate.

Insanity during maternity occurred more frequently in women about to give birth to an illegitimate child. Infanticide and suicide were common. To produce sleep the author preferred paraldehyde. As showing the influence of heredity, the author knew of a family members of which had shown insanity during four generations on reaching a certain age.

The insanity of the menopause was of the depressed type, frequently with suicidal impulse, yet the prognosis was favorable where there was no hereditary taint. Out-of-door life and change of climate were recommended.

The most common form of insanity of the last period was that of senile dementia. It was rather a retrogres-

sion of the mind. In senile melancholia seventy-five per cent. of the cases showed suicidal tendency. The author had found most satisfactory results from opium, and at this period there was little danger of the opium habit.

In discussing the paper Dr. William Leszynski said he had never felt satisfied that the physiological epoch of childhood had much to do with the development of insanity, although it was a settled fact that hereditary predisposition was a prime element. Puberty in the boy also had little influence since the change was so gradual.

Dr. E. D. Fisher said women at puberty were particularly subject to nervous disorders, as hysteria, mental depression, etc., and required a change of surroundings, for their chances were not good if treated at home. He endorsed the author's recommendation of opium in senile dementia.

Dr. Collins thought some of the divisions made in the paper somewhat artificial, although they might serve to make the subject clear.

The epoch of childhood as predisposing to insanity particularly seemed artificial, and that of old age was very variable, and pertained to degeneration of the arteries. In the insanity of the puerperal period the time had arrived for laying more stress on infection as a cause.

Dr. Van Fleet thought the term heredity a misnomer, that it had been much abused; but the basis of his belief seemed to be fear of its influence on the imagination of those giving a hereditary history.

Dr. Bryson related two instances to show the injurious effects of the same physical conditions enforced upon women as upon men in attaining an education. She thought the same mental training could be acquired and yet allow for differences in physiological processes.

The usual collation was served.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

SANITARY CONGRESS—PRESIDENT'S ADDRESS—HEALTH EXHIBITION—CONFERENCES OF OFFICERS OF HEALTH, SANITARY INSPECTORS, ETC—OVERCROWDING OF HOUSES—DR. KLEIN ON TYPHOID—DEATH OF DR. GREENHILL, THE SCHOLAR OF THE PROFESSION—OPENING OF THE LONDON MEDICAL SCHOOLS.

London, September 29, 1894.

This week we have had another congress, viz., the fourteenth of the Sanitary Institute, which met in Liverpool. On Monday the members were received in the town hall by the Lord Mayor, and the President, Sir Francis Powell, Bart., M P., delivered his address. He passed in review the progress made in the last few years, especially in connection with the Acts of Parliament which dealt with the subject. It was with a note of intense satisfaction, if not of exultation, that he surveyed the progress of the last twenty years, in which more than fifty-six million pounds had been expended under the sanction of the Local Government Board, while local acts had authorized the expenditure of a further sum of more than sixty-seven millions. He then passed to the question of quarantine, and showed how much better we have fared without it in regard to cholera. On vaccination he pointed out that it is the part of true wisdom to be guided by those best qualified to judge, and that those who were in doubt might be reassured as to the harmlessness of the preventive measure by the increased care and precautions which are taken to secure the safety as well as the efficacy of the operation. Among other subjects noticed were the dissemination of phthisis, the alleged increase of insanity, food adulteration, factory legislation, the smoke nuisance, river pollution, and pauper children. A cordial vote of thanks was given to the President. In the evening an exhibition of sanitary appliances, etc., was opened by the Lord Mayor. This exhibition was kept open and musical selections given each afternoon and evening. Here also demonstrations in cooking were given.

On Tuesday the several "conferences" began their work. That of the Medical Officers of Health was presided over by Mr. C. E. Paget, the able officer of Salford, whose address dealt fully with the questions of the Health Acts and diplomas in public health. He spoke freely of the imperfections he had observed in the administration of the acts, but while admitting we might not be able to remove them for a time, urged that their continuance cannot rob us of the stimulus to exertion afforded by the labors of those who have gone before. Moreover, we may live up to those records and make the imperfections we protest against more and more glaringly manifest until those beyond our profession see them and insist on their amendment, so that if we fail to win reform we shall pave the way for others to secure it.

In the evening Dr. G. B. Longstaff, gave a lecture on the overcrowding of houses on land, illustrated by photographs of the Hamburg slums.

On Wednesday Dr. Klein presided over the Section of Sanitary Science and Preventive Medicine. His address was on typhoid fever, as to which he held that sanitarians might continue to regard the disease as specific, and derived from case to case; not, as some had suggested, as originating *de novo* through the bacillus coli communis. This does not render the duty of preventing sewage contamination less urgent, for although the typhoid germ without the bacillus coli communis might not be capable of causing typhoid fever, the presence of that bacillus indicated excremental contamination in which possibly specific typhoid germs might be present.

The conference of sanitary officers was presided over by Mr. Vacher, F R.C.S., and that of domestic hygiene by the Lady Mayoress. In each of the sections interesting papers were read and discussions carried on. Needless to say that hospitality and entertainments were to the fore, and that the members had reason to feel satisfied with a pleasant visit to Liverpool combined with a show of zeal in the cause of sanitary progress.

Dr. Greenhill is no more. He died on the 19th at the ripe age of eighty-one. He was one of the greatest scholars in our profession. William Alexander Greenhill graduated at Oxford in 1841, and was recognized everywhere as an ornament of that ancient seat of learning. Even your younger readers will remember his name as the editor of the best edition of Sir T. Browne's "Religio Medici." Others will call to mind his Latin edition of Sydenham, his translation of Rhazes, or his critical edition with Latin version of Theophilus. These alone should suffice to show that the profession has lost in him a scholar of high order, but those who came into contact with him felt that he was much more—a true gentleman, sincere friend, a devout Christian, a sanitary reformer, destitute of self-interest, and withal crowned with the deepest modesty and generous intentions. He went to Hastings in 1851, and practised there until he retired some years ago, and devoted his remaining time to his literary work, on which he was employed up to the date of his decease from syncope. In Hastings his noble figure was familiar enough, and he was naturally regarded with reverence on the one hand by those who had been his patients, on the other by those who were aware that he was perhaps the greatest scholar which our profession has produced during the century.

London, October 2, 1894.

The custom of opening the session of the medical schools with an "Introductory Lecture" addressed chiefly to freshmen—though giving way further to dinners and *conversazioni*—is still kept up at some of our hospitals, and where the lecturer is fitted for the post has much to commend it. Formerly, October 1st was regarded as an event in the *annus medicus* which every institution and every student ought to observe, and old practitioners, whenever they could, visited their *alma mater* on that

day, and renewed friendships and friendly intercourse. The invasion of the dinner is, in this respect, to be regretted, besides which the lecture afforded the opportunity of words of warning and advice to young men which the teachers have seldom the opportunity of giving.

Yesterday several schools opened with the old "Introductory." At the Westminster Hospital Mr. Hartridge congratulated the students on choosing the profession which called for their highest intellectual powers, brought them into contact with suffering and pain, and called forth those deep feelings of sympathy which united man to man. No other profession could stand on the same basis for usefulness. Look at the immense amount of work which was so freely given by the members of their calling; all the hospitals depended upon it for their existence. Look also at the health of this great city, with its millions of people, and they would have some idea what medical science had done in the department of preventive medicine. If it was the noblest and most useful, it was at the same time the most arduous, the most difficult, and one which received the least notice and reward from the state and the public; the former only recognized those who were able to support its claims. Most of them were not politicians; they were not a powerful body to be conciliated, able to turn the tide of an election or decide the fate of a Cabinet. Much of this was their own fault, because it was a duty they owed both to their profession and their country, to take an interest in politics. He anticipated the time when they should be fairly represented in both Houses of Parliament, and when they would have a Minister of Health in the Cabinet. To the students he would say that much benefit would accrue by raising the standard of the entrance examinations. He should like to see Latin and Greek replaced by modern languages and scientific subjects, which would be equally effectual as a mental training, and far more useful. Working too much was almost as bad as working too little. In regulating their study hours they must be careful to look after their general health. Medicine was a study which should be approached in a scientific spirit, and they could always make their work scientific, in whatever branch they were engaged, by training the mind in the power and habit of accurately observing facts, and should always have the courage to do what they considered right, and allow the consequences to take care of themselves. Referring to the success of "quacks and charlatans" who advertised so largely, he said these advertisements were hardly a credit to journalism; most were of a flagrant character and without a vestige of truth, out of which certain papers made a rich harvest. The so called religious papers were the worst offenders. But of all irregular practitioners the bone-setter was the one whom the public held in the highest esteem. He knew nothing of anatomy, had never been in a dissecting room, but was supposed to be born with special gifts as regards bones and joints. To the bone-setter every injury was a bone out of place. He wound up by saying that advertising quacks, protected by diplomas, were far worse than the unqualified man, and a disgrace to the bodies whose diploma they held, and their existence a disgrace to the legislation of a civilized country.

At St George's Hospital Dr. Isambard Owen took for his subject the importance of mental training in medical study. Accurate observation, he said, was the foundation of all medical work; to it there was no royal road —only the old fashioned way of constant, close, personal observation of case after case, under skilled supervision and systematic reduction to written or graphic records of what was observed. He urged that if school children were systematically trained into more exact habits of arithmetical perception and expression more would be done to render the rising generation scientific than the suppression of Latin in favor of biology could possibly effect. Adverting briefly to the position of the London University and the Gresham Commissioners' scheme, he said that while a tribute of sincere gratitude was due to them for their painstaking labors, the merits of the scheme itself were matter of controversy, and that he had never concealed his own sense of the danger to soundness of medical education with which certain parts of it were charged.

At Middlesex Hospital Dr. Robert Boxall touched upon the steady increase in the number of doctors in recent years, and, by a series of statistical tables and diagrams, showed that the ranks of the profession in England and Wales had been gradually swelling out of proportion to increase in population. Drawing deductions from statistics, he said it was manifest that the outcry which had been raised against the out patient departments of the large general hospitals was unwarranted —at least, in comparison with what might be said of more recently established institutions, most of which had no teaching function to fulfil. It was an undoubted fact that in all the hospitals the number of out patients had increased, but so had also the number of in-patients, and an outcry against the one was no more justified than an outcry against the other. But, inasmuch as medicine was in itself a progressive science, it would be a wonder indeed if the medical charities of Great Britain, which had long been the admiration and wonder of the whole civilized world, failed, as years rolled on, to enlarge their walls and to increase the scope of their utility.

At St. Thomas's Hospital an address was delivered by the Rev. Dr. Merry, Rector of Lincoln College, Oxford, who spoke upon the half-serious, half-jesting strictures passed by Plato on the practice of medicine in his own time, a subject which the great philosopher humorously introduced in the form of a criticism on medicine as practised in the days of Homer. Plato professed to feel the greatest satisfaction in the rough and ready treatment of the heroes who fought under the walls of Troy. The degenerate system of coddling Plato strongly condemned, as tending to the survival of the unfittest, and the production of sickly children, whose presence was not to be endured in his commonwealth. The very existence of hospitals, said the philosopher, was a proof of a degenerate age, when men had impaired their health by intemperance and indolence. No one had a right to be an invalid, and the "coddling" process would never have been introduced if the profession had not been demoralized by wealthy patients, who bribed the doctors to prolong their miserable and useless lives. Passing from this humorous criticism, the lecturer quoted a more serious sentence from his author, recommending that the physician should not be in robust health, and should have known what illness is in his own person. Rightly interpreted, it contained the golden maxim that the physician must not only bring his skill, but his sympathy, to bear upon his patient. The world at large was taking a growing interest in medicine, and men were looking in high hopes to the progress of medical science.

At University College Professor H. R. Spencer said that the treatment of wounds on antiseptic principles had revolutionized surgery and obstetrics, and he believed history would record it as the grandest achievement of the century. In medicine, too, great advance had been made in diagnosis and treatment, as a result of the employment of the experimental method of research, which only the ignorant condemned. As to legislation, which was urgently required for the benefit of the public as well as the profession, he said that autopsies in cases of unnatural or suspicious deaths should be only performed by expert medical jurists and pathologists. Practice by unqualified persons and by medical men whose names had been expelled from the Register should be absolutely forbidden. And the law should be severe on those unprincipled persons who risked the lives of the ignorant poor by circulating among them the cruel slander that patients were experimented upon in hospitals. Adverting to the abuse of hospitals by well-to-do patients, he thought hospitals should be able to recover fees from persons obtaining gratuitous treatment by fraudulently representing

themselves to be poor. In conclusion, he said the profession they had chosen was an arduous one, and yet it was the most fascinating of all. No social class could look down upon those to whom such sacred interests as reputation and life were intrusted. Greater trust hath no man than this, that he trusted his life to his friend.

At St. Mary's Hospital Dr. Scanes Spicer took for his subject, "Medicine as a Profession." Its social advancement, he said, of late years had been remarkable, and had been parallel with the wide general culture and interests of the average modern doctor, who was something more than a mere prescriber of physic. Doctors were more and more finding their way into Parliament, the Privy Council, and the national government. It was a grievance with the profession that it was not directly represented in the House of Lords, where the counsel of medical men would not only add to the efficiency of public work, but signalize the national recognition of the value of medicine to the community. The increase and development of specialism was one of the most striking facts in the medical history of the latter part of the nineteenth century. Specialism was destined to play an even more important part in the development of medical art. He defended it from the charges of shallowness, self sufficiency, and unscrupulousness that had been brought against it. Attention was drawn to the remarkable development attained in less than forty years in the specialty of diseases of the throat and nose, due chiefly to the truly marvellous results of local treatment. On the Continent there was hardly a university without one or more professors of this specialty, and well-appointed clinics; a marked contrast to the indifference and neglect which this branch met with in the United Kingdom. Specialism now enjoyed, more than ever before, the respect of thinking members of the profession and the public; but there was need for still further rapprochement between specialists and the general body of the profession, in the interest of both. Each was necessary for the other, for no one could be an all-round specialist.

At the London School of Medicine for Women, Miss Maida Sturze, M.B., London, alluded to the need of cultivating from the first the scientific habit of mind, seeing that its possession was invaluable to the medical practitioner. The importance of general culture and experience as an aid to the right understanding of others, and as a help in the individualization of treatment was pointed out. The wisdom of devoting time to learning something of the natures and abundant vitality of healthy children was dwelt upon, as the only means of fully understanding their needs when ill, and probably in the future the profession would regard with surprise the fact that in the nineteenth century sick children were so often admitted into hospitals instead of carrying them into the fresh air and sunshine outside cities.

THE ESQUIMAUX AND THEIR TEETH.

To the Editor of the Medical Record.

Sir: It has long been a disputed question as to what effect diet, climate, and mode of life have upon the structural formation of the teeth of mankind. Desiring to make my observations among a people who fitted the conditions of such an investigation as nearly as possible, I chose the Eskimo as my most available subjects, and with that end in view I eagerly seized the opportunity to become one of a number who visited the icy shores of Greenland last summer. Of the interesting people who inhabit this arctic region, the pure Eskimo are fast disappearing through marriage with the Danes; the present generation being known as Greenlanders, or Danish Eskimo. The men are taller and lighter in color than the native Eskimo, shading from bronze to dark tan. Their hair is black, generally straight, long, and unkempt, and, falling over their faces, presents a savage appearance. Their eyes are small, round, and very sharp, with large deep wrinkles extending from the outer edge of the eye to their high cheek-bones. These wrinkles are caused by the habit of constantly squinting to shade their eyes from the intense glare of the ice during the long arctic day. The women are short, rather stout, and comely looking. Their skin is lighter in color than the men's. Their eyes are clear, bright, and similar in shape to the Chinese. Their hair is twisted in a hard knot on the top of the head, held in a place by a ribbon or a rag, the color of which denotes their station in life. Blue for a married woman, red for a single woman, black for a widow with the addition of a narrow strip of white if desiring to marry again. The unfortunate or fallen women of the tribe are designated by a green ribbon bound around the hair. Their food, which consists wholly of fish and flesh, of the various animals which inhabit this region, together with the fat and oil obtained from them, is generally swallowed or bolted without mastication. Their teeth, which articulate squarely upon the cutting edges of the incisors, are worn off in many cases nearly to the gums, giving the appearance of double teeth all around. Caries is not common, although in several cases the first molar teeth were decayed, while all other teeth in the same mouth were sound. In color their teeth have a yellow cast; the structure is more like ivory. The palatal arch is broad and shallow, the mouth large, with firm lips, and jaw square shaped.

From twenty-eight impressions taken in modelling composition, I made as many plaster of Paris casts of the upper and lower jaws and teeth, which were unfortunately lost, together with a valuable collection of Eskimo curios, weapons of the chase, skin, and fur garments, kyaks, etc., when our vessel was wrecked off the Greenland coast, near Sukkertoppen. Despite the unfortunate termination of our expedition, I trust it will be my fortune to again visit the Arctic region, and make a similar collection of casts and notes, to add to the large number now on exhibition at the Medical Museum in Washington.

Roswell O. Stebbins, D.D.S.

55 West Forty-fifth Street, New York.

APEX CATARRH OR TUBERCULOSIS?

To the Editor of the Medical Record.

Sir: In your issue of September 22d I notice a short paper on "Diseases of the Ear and Upper Air passages in Apex Catarrh," by Dr. Howard S. Straight, of Cleveland, O. If I may be permitted the use of a small space in your journal, I want to object to the use of this expression "Apex Catarrh." If Dr. Straight will make careful, and if necessary, repeated examinations of the sputa in these cases of so-called apex catarrh, I think he will find that they are nearly all cases of more or less early tuberculosis. Acute simple catarrhal affections of the chest—"cold," "bronchitis," etc.—do not limit themselves to the apices, and I think that the existence of subacute and chronic affections of the apices of a simple catarrhal character is more than doubtful. In one of the cases cited by Dr. Straight as apex catarrh it was certainly so, for he states that a few days later the patient, a boy aged twenty, died "from a profuse hemorrhage from the lungs."

Post mortem records prove conclusively that tuberculosis is a much more common and at the same time a less to be dreaded disease than is generally supposed, since a large portion of the dead from all causes show healed tuberculous lesions. If this view is correct, and limited apex catarrhs are tuberculous in character, it is certainly a great gain to call them by their proper names and to avoid the use of terms which are misleading and calculated to give rise to a sense of false security very dangerous to the interests of the patient. This view accords very well, too, with what the doctor has to say upon diseases of the ear and upper air passages in such cases, since it is a matter of general experience that the existence of even a slight tuberculous affection in the

lungs renders disorders of the ear, nose, and throat much more refractory to treatment. Physicians in phthisical health resorts have been trying for years to arouse in the profession at large an active appreciation of the importance of recognizing tuberculosis in just these early beginnings. In no other way, I believe, is it possible to save them. Palliation can be had at almost any time, but cures can not.

Yours truly,

H. B. MOORE, M.D.

COLORADO SPRINGS, September 26, 1894.

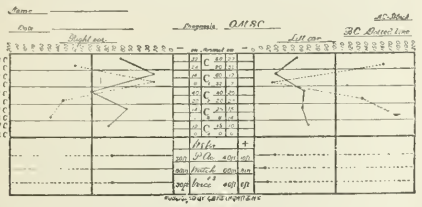
New Instruments.

THE APPLICATION OF THE GRAPHIC METHOD TO HEARING.

BY W. HARVEY SMITH, A.M., M.D., C.M.,

WINNIPEG, MANITOBA.

THE graphic method, when employed to demonstrate physiological or pathological variations from the normal or to express relations and ratios between different bodily functions or conditions, is recognized by the medical profession as an invaluable adjunct to diagnosis. The chart here shown has been devised for the purpose of applying this method to hearing, and thus to provide the otologist with a means of representing the results of tuning-fork and other tests in a form more intelligible than that commonly used.



In this chart the hearing power is expressed in percentages which are based upon the results obtained from the use of Hartmann's tuning forks, the acoumeter, the voice, and the watch. The percentage line on each side of the central columns is numbered from 0 to 200, the 100 line being the line of normal hearing for all tests. The percentages employed are based upon the averages of a large number of tests made upon normal ears, and modified by comparing them with Hartmann's results.

These averages have been printed in the middle column opposite the different tests. Spaces for marking the percentages of aerial and bone conduction are provided, one above the other, opposite the different C's. The aerial conduction is represented by joining together the consecutive aerial percentages with black lines, while red lines are similarly used for the bone conduction. At the bottom of the chart is shown the result of the Weber test and the percentages of hearing for the acoumeter, the voice, and the watch; and in the spaces to the right and left of the middle column the height of time or distance at which (in figures) the standard sounds are heard. A rapid calculation of the percentages can be made from the percentage table which is printed on the back of each chart.

It is obvious to those who possess a practical knowledge of otology, that, owing to the influence of constitutional and other factors, the results obtained from any or all hearing-tests can give but an approximate idea of the condition of the auditory functions. This being true, how essential it is that that system should be adopted for the expression of hearing-power which will afford information in the most intelligible and rational form!

By applying the graphic method to hearing in the manner described, the slightest deviation from the normal can be perceived at a glance, and the comparative differences between the aerial and bone conduction, and the results of the acoumeter, the voice, and the watch tests can be more readily appreciated than by using the numerical system at present in vogue.

These charts can be obtained from Mr. E. B. Meyrowitz, of New York.

A NEW SNARE.

BY WILLIAM A. MARTIN, M.D.,

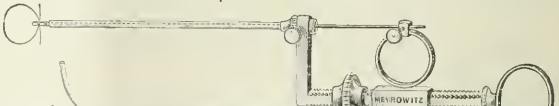
PROFESSOR OF LARYNGOLOGY, SAN FRANCISCO POLYCLINIC.

THE snare described in the following lines is a combination of the meritorious principles found in other snares, rendered possible by the shape of the handle designed by the writer. Most of the snares in present use have one or more objectionable features, the principal one of which to the writer is the time lost in rewiring. This is particularly the case in polyclinic practice, where one either has to have a number of snares prepared for use, or must have an assistant with an extra snare at hand.

The only original principle in the snare is in the shape of the handle. It was designed in this manner in order that the stiff rod into which the wire is threaded could be used, and at the same time prevent the obstruction of the view by the hand of the operator.

The following are a few of the numerous advantages of the snare. One can have any desired number of cannulas with the contained rod wired ready for use. The time occupied in taking out one cannula and replacing it with another is not more than half a minute. The same loop can be shoved out and used again and again, as often as six or seven times.

The economy in wire is not a minor consideration, especially in polyclinic practice. The loop can be turned and held in any desired plane by simply revolving the rod. Anyone who uses the snare for removing tonsils will appreciate this principle. A loop of larger size than permitted in any other snare may be used when the finger-rings come to the end of the slide; the winged screw may be loosened and the rings slid forward on the rod and reclamped, a procedure which in the ordinary snare is awkward and occupies considerable time. The loop may be placed around the part to be removed and drawn taut before attaching to the handle, a desirable feature in post-nasal growths where one has to use both hands. The handle is threaded as in the Bosworth snare, so that the loop may be slowly tightened when desirable. The same handle could be used with the Schrötter laryngeal instruments, it being similar to the Streck handle excepting the double bend. The same handle could also be used for ear instruments, both for cutting instruments



as well as for a snare. Since designing the above snare I see that a similar bend for ear instruments is advocated by Barclay,[1] of St. Louis. In his instruments the angles are not 90°, but by prolonging the shaft of the instrument and the handle they meet at an acute angle.

The snare is made according to my directions by E. B. Meyrowitz, in the most satisfactory manner, and he has also kindly furnished the accompanying cut.

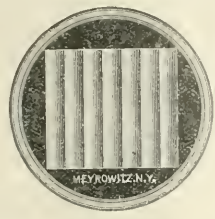
An Italian Hospital has been established in Tunis for the benefit of residents of that nationality.

[1] Archives of Otology, vol. xxii., No. 2.

AN IMPROVED PHOROSCOPE.

By WILLIAM F. AIKEN, M.D.,
SAVANNAH, GA.

In using the ordinary rod-test for heterophoria, the writer has always been inconvenienced by the narrowness of the opening. About a year ago it occurred to him to substitute a series of parallel rods for the single rod, and a crude self manufactured instrument has since then done excellent work. Recently, Mr. E B. Meyrowitz, of New York, has constructed from drawings an extremely pretty instrument, as here illustrated. In practice, the elongated images produced by the several glass cylinders fuse into one long, continuous, and very brilliant bright band. This band is so long, indeed, that when so placed as to be vertical, it extends from floor to ceiling.



Apart from the increased length and brilliancy of the image produced, the instrument possesses the great advantage of a large square opening before the pupil. If, owing to faulty adjustment of the trial frame in which the instrument is placed, the pupil fails to correspond with the exact centre of the opening, it makes no difference, any point within the square affording a perfect view of the image. This large working space saves the annoyance of carefully adjusting a heavy trial frame, the light single frame being more convenient, and more comfortable for the patient. Moreover, the efforts patients make to see through the stenopæic slits and openings of other tests add a dynamic factor to what should be a purely static finding as regards the muscular equilibrium; with the large opening no moving about of the head or eyeballs is excited, the eyes resting quietly in their natural position.

It should be noted that the instrument is a phoroscope, not a phorometer. The amount of deviation shown has to be measured with prisms. Using a rotary variable prism in the other side of the trial frame, however, makes the most efficient form of phorometer, as both eyes look through large openings, and either instrument may be used separately. Mr. E. B. Meyrowitz has suggested, nevertheless, that the two instruments can be combined, making a single phorometer, in case of demand for such an arrangement. I wish to state my indebtedness to Mr. Meyrowitz for his courtesy and readiness in conceiving and executing my idea; likewise for the accompanying cut.

Medical Items.

Contagious Diseases — Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 13, 1894.

	Cases.	Deaths.
Tuberculosis	105	99
Typhoid fever	35	10
Scarlet fever	53	4
Cerebro-spinal meningitis	1	1
Measles	18	3
Diphtheria	119	30
Small-pox	1	0

There are no Public Baths in Rome, according to a statement recently made by Professor Celli.

The Oldest Physician in Great Britain is Dr. Salmon, of Penllyn Court, South Wales. He was born in Wickham Market, Suffolk, in 1790. He is also the oldest Freemason in the country, having joined the order over eighty years ago.

The Pain of Inoperable Cancer has been found by Aikmann to yield in many cases to salicylate of sodium in doses of ten grains three times a day.

The Cholera Bacillus becomes attenuated, it is said, by exposure to direct sunlight, and will then serve as a preventive vaccine.

Illegal Sale of Patent Medicines.—Grocers in England who sell patent medicines are being prosecuted, on the complaint of the apothecaries, under the law prohibiting the sale of poisons without a special license.

Mrs. Sarah Thomas, of Buryport, South Wales, recently celebrated the completion of her one hundred and sixth year. The Princess of Wales sent her a letter of congratulation and a check for one hundred and six shillings, a shilling for each year of her life.

Delinquents in Olympia.—The publisher of our esteemed contemporary Γαλητός has been compelled to print a black list of subscribers to the journal who are in arrears for three years. Of these there are eight, two of whom live in Olympia.

The Face as a Guide in Diagnosis.—The physiognomy of the sick presents innumerable shades of expression. These are certain facial lines and wrinkles which are of positive value in diagnosis, but in the use of these it is important that we discriminate between those natural to the face, and those which are developed by disease. In childhood, however, there are few or none of the acquired lines found in adult life. We may therefore be quite sure of our indications in this class of cases. The more important of these are as follows: The transverse rugæ, the oculo-frontal rugæ, the oculo-zygomatic line, the linea nasalis, the linea labialis, and the linea collateralis nasi. The first two are situated upon the forehead, the first of which, the transverse rugæ, are formed by the action of the occipito-frontalis muscles, and are believed to be indicative of great pain from causes outside the cavities of the body. The next, the oculo-frontal rugæ, are vertical lines extending from the forehead to root of nose; they are formed by the corrugator supercilii muscles; they express distress, anxiety, and extreme pain from some internal cause, cranial, thoracic, or abdominal. They oftentimes indicate an imperfect crisis, and in acute diseases often a fatal termination. I have observed this many times, and whenever I see these peculiar lines I am very solicitous for my case. In excessively severe headaches these two described rugæ may exist simultaneously, and when during the course of an acute disease the two meet abruptly, they denote a developing serious lesion of the brain or some of its coverings, and when I meet a case where this condition exists, I feel justified in advising of the grave nature of the disease and a consequent grave prognosis, a lingering case, if not fatal. The linea oculo-zygomatica extends from the inner angle of the eye down and outward, crossing the face below the malar bone. This is believed to indicate a cerebral or nervous affection in children, in adult life masturbation or venereal excesses, and is frequently a very valuable aid in this class of cases.

The linea nasalis extends in a semi-curved direction from the upper border of the ala nasi downward to the outer margin of the orbicularis oris muscle; this line we find very marked in advanced cases of marasmus, inanition or such diseases as these simulate; in adult life, phthisis and atrophy. Where only the upper half, the linea nasalis proper, is present, it is quite a reliable indication of intestinal disease, typhlitis or entero colitis; it may be present in severe colic, although not marked, as the attack is remittent and of short duration. When the lower half, or linea buccalis, is alone present, it indicates some disease affecting the stomach. It is quite prominent in chronic dyspeptics, and when the two, as last described, together with the linea oculo zygomatica, appear conjointly, they may be regarded as positive evidence of worms, and if the circumscribed red cheeks, the pallor of face around the mouth inside the linea nasalis, to-

gether with the bright, fixed, and wild expression of eye are present, no further evidence of the presence of these pests is necessary. The linea labialis extends from the angle of the mouth downward without marked termination till lost in the lower portion of the face. It is usual in those diseases which affect respiration, and is a more important diagnostic sign in childhood than in adult life; it may be observed in croup, both true and false, in acute laryngitis and capillary bronchitis; in adults most prominently in asthmatic subjects. The linea collateralis nasi extends in a semi-curved direction from the ala to the chin. It is situated further out, outside the lines just described, and is a reliable guide to diseases of the thoracic and abdominal viscera; in fact it may be considered as positive evidence of a lesion in one of these regions, and when with the above is coupled the painful expression about the mouth, together with the peculiar fold on either side the mouth, we may be almost positively certain that the lesion is abdominal. It is very marked in typhus abdominalis, also phthisis abdominalis. The above described are the more important and most frequently met by physicians, and to those who have not studied the physiognomy in this manner I would say, carefully note these lines, wrinkles, and expressions; they will aid you in the diagnosis of many an obscure case, assist you in a prognosis that oftentimes will seem little less than inspirational to your patients or their friends.—Dr. S. M. Spalding.

Nitrate of Cobalt is said, by Dr. Antal, a Hungarian chemist, to be an effective antidote to cyanide of potassium. He has tried it in upward of forty cases of poisoning by this substance, in every instance with success.

In One Thousand Towns in Minnesota the people live and die without the help of a homœopathic physician, so says a contemporary in that State.

Phthisis is one of the most common diseases of sailors, more seamen dying from that than from either accident or heart disease.

Dr. Y. May Kin, now practising in Kobe, Japan, was the first Chinese lady to receive a medical decree in America, and the first scientifically educated female practitioner in Japan.

Combined Carbolic Acid and Chloroform in Typhoid Fever.—The experiments of Werner, at St. Petersburg, in 1890, showed that a one-half per cent. solution of chloroform will kill the bacillus of enteric fever. In 1892 McIntyre, of Glasgow, proved that carbolic acid controls the development of this bacillus, and also exercises an antiseptic action on the intestinal contents. Acting on these hints, Dr. R. H. Quill, of the British Army Medical Staff, stationed at Hirkee, India, has treated with a combination of carbolic acid and chloroform all his cases of typhoid fever for over a year, and reports in the *British Medical Journal* of April 28th that perfect recovery has followed in each case, without the advent of any severe symptoms. In India the mortality of enteric fever is much greater than is usually experienced in temperate climates, which fact increases the value of the test. He used a mixture of thirty six minims of pure carbolic acid, two fluidrachms of spirit of chloroform, three fluidrachms of compound tincture of cardamon, two fluidounces of sirup of hemidesmus, and added chloroform water to make twelve fluidounces. Every two hours the patient was given two tablespoonfuls of this carbolic mixture in a like quantity of iced water. On the first visit three grains of calomel were given to the typhoid patient. On the next day, five doses of the mixture were given, and ten doses on the third and following days until there was a fall of temperature, and the general condition of the patient was distinctly improved, the doses then being gradually reduced to seven, five, and three in the twenty-four hours. To prevent a relapse, the mixture should be continued for at least a week after the temperature is normal, giving from three to five doses each day. Twelve of the patients were in the station hospital, and one took two fluidounces, in all, of pure carbolic acid and the same of chloroform, while another took one and one-half fluidounce of each, the urine occasionally becoming high colored, but never black.

Carbolic acid combined with chloroform reduced the average duration of typhoid fever, with a continuous depression of the febrile temperature. The tendency to diarrhœa was checked, the abdominal distention kept under control, and the stools were almost completely deodorized. There was early cleansing of the tongue, dryness of which was rare and brief. There was no tendency to stupor or delirium, and the patient retained the usual clearness of intellect. The few relapses were of short duration, and secondary complications did not occur. The food was always well digested and assimilated, and convalescence was rapid. In the past, carbolic acid has not been generally adopted as an intestinal antiseptic, probably on account of the small doses given. Full doses, at short intervals, freely diluted and suitably combined, must be given to make carbolic acid efficient in enteric fever.

The Pennsylvania Hospital is to be renovated, its drainage being said to be very defective.

Asparagus causes a reduction in quantity, and increased concentration of the urine, according to Dr. Elliot Daunt.

Dr. Beaven Rake, whose death occurred in Trinidad on August 25th, succumbed, as we surmised in a previous notice, to yellow fever, which has been epidemic in Port-of-Spain during the past summer.

Dr. Henry Hoffmann Donner died in Frankfort-on-the-Main on September 20th, aged eighty-three. Although a skilful physician, he was better known to the world at large as a poet and humorous writer. His best known book was "Struwelpeter," which ran through no less than one hundred and fifty editions in Germany, and was translated into every European language.

The Influenza has been very prevalent in Buenos Ayres during the four months just past, which constitute the winter season in that latitude.

The Cult of the Rotten Calf is the gentle term applied to the prevention of small-pox by an English anti-vaccinationist.

A London Anti-vivisection Journal publishes these pathetic lines:

TO A VIVISECTOR.

Oh, cruel man, how dost thou dare,
With selfish ends in view,
To torture thus a creature fair,
Who never injured you?

Do you not know the God of love,
Whose are the creatures all,
Looks down from His high throne above,
And hears them when they call?

He sees the hand with blood-stained knife,
He hears the piteous cry!
Then spare, oh spare, that poor beast's life,
Oh do not make him die!

The God who made him made you too,
For He did all things make;
Then show much love in all you do,
For your kind Maker's sake.

If the gentle author had a child ill with diphtheria we wonder if he would consent to the use of the diphtheritic antitoxin, a product of the vivisectionist's work on horses. And does this poet eat capon, ride the gelding or hunt the fox?

Taking the Case.—*Patient:* Showing her arm badly bitten.

Doctor: Bitten by a dog, madam?

Patient (with withering dignity): No, sir. By another lady!

BRONZE STATUE OF THE LATE DR. J. MARION SIMS ERECTED IN BRYANT PARK AND PRESENTED TO THE CITY OF NEW YORK, ON SATURDAY, OCTOBER 20TH, BY THE SUBSCRIBERS TO THE FUND.

Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 46, No. 17.
Whole No. 1251.

Medical Addresses.

DR. J. MARION SIMS—SURGEON AND PHILANTHROPIST.

AN ADDRESS DELIVERED OCTOBER 20, 1894, IN BRYANT PARK, NEW YORK, ON THE UNVEILING OF THE STATUE OF DR. J. MARION SIMS.

BY GEORGE F. SHRADY, M.D., .

NEW YORK.

LADIES AND GENTLEMEN: We have met on this occasion to do honor to a medical man, and through him to show a becoming appreciation of the labors of his fellows.

Strange as it may appear, in consideration of the motive which has actuated this recognition of valuable services to mankind, and the previous opportunities that have been, from time to time, offered for conferring similar honors on the profession, this is the first instance in this country in which an heroic statue has been erected to a member of that fraternity.

Heretofore Fame has restricted her tributes to achievements in every other line of high human endeavor—War, Poetry, Music, Literature, Art, Patriotism, Statesmanship, and Philanthropy have in turn mounted the pedestal, while the Genius of Medicine, with finger upon closed lips, has humbly and mutely awaited the verdict of an appreciative humanity.

This new departure which we this day inaugurate can be hailed, from many points of view, as an omen of good import, as the beginning of an end in which cherished traditions shall no longer hamper the well directed efforts of such as work in other spheres of human usefulness. The public, however, is not so much to blame for lack of a general appreciation of the work of the doctor as would at first appear. It has in reality no means of estimating distinctive merits. It was, therefore, proper, in order to initiate such a movement as the present one, that the profession itself should take the lead, and indicate a fitting subject for such an honor. This was done by the MEDICAL RECORD, which made an appeal to the profession in this and other countries for funds with which to erect a monument to the memory of one of its acknowledged leaders.

A committee was appointed, of which the late Dr. Fordyce Barker was chairman, which comprised leading specialists from every part of the United States. Our own city was represented by Drs. T. Gaillard Thomas, Thomas Addis Emmet, William T. Lusk, William M. Polk, Paul F Mundé, the editor of the MEDICAL RECORD, and Mr. William H. S. Wood, as treasurer of the fund.

The subscriptions were mostly limited to one dollar each, and coming as they did from members of the profession in every part of the civilized world, attested, in an unmistakable manner, the good name and great fame of the American surgeon.

This distinction came, then, from his peers, who were best able to judge his qualifications for it, and who with one accord were delighted to honor him.

It was eminently fitting also that such a tribute should be paid to American surgery in general, through one of its chief representatives. He was a product of the soil as well as the exemplification of one of the principles which has placed American surgery where it is to day, holding the sceptre of the world.

Nothing in all the line of progress during the century has acquitted itself so creditably as this very science of life saving by operative procedure. And America specially points with pride to her great achievements in this noble art, to her notable discoveries in alleviating human suffering, her successful efforts in prolonging human life, and in the accuracy, skill, and daring of her brilliant operators.

America gave ether to the world, invented the new sleep which numbs the touch of sharpest steel, brings sweet peace in the eternal war with agony, and wafts pain to oblivion on the drowsy wing of night. She opened new fields for exploration within the human body, made abdominal surgery with its brilliant successes the possibility of the age, and with dauntless blade and master hand snatched victory from the long-hidden entrenchments of death. In fact in every department of surgical procedure the American surgeon has left his impress for good either in the invention of new methods or in the modification of old ones; and has given American surgery a world-wide recognition for originality of conception, boldness of execution, and success of practice.

In his own department Sims, a born and typical American, was a leading worker. He established a school of his own, which has now won fame throughout the world. Indeed, it is safe to say that Sims's name is associated with more original operations and more new instruments for making such operations successful than that of any other American surgeon. His was the germinal thought implanted in a disposition for untiring work, which changed impossibilities into triumphs, restoring health and happiness to countless numbers of suffering womanhood.

If it be true that no fame is lasting unless founded on labors which promote the happiness of mankind, the name of Sims must live as long as generations succeed each other, and will punctuate the progress of history by its cherished memory.

But Sims, although ambitious, did not seek for fame. When it came to him he viewed it with an innocent surprise. When it was all done, when during his tour of the capitals of Europe, operating in the large hospitals and before the renowned surgeons of the day, his breast studded with the starry decorations of France, Portugal, Spain, and Italy, he could not understand why he was so cordially noticed, forgetting that he himself was the focal point toward which all the then great lights centred.

Indeed, it was said of Sims that he could practise and earn his living in any city of Europe, by virtue of what became for him a cosmopolitan reputation.

He was, however, virtually alone in his conviction of ultimate success. His few professional friends, who were at first enthusiastically hopeful, became, in the face of his early failures, mistrustful and discouraged. While they admired his ardor they pitied his delusion. In his darkest hours came confidential advice from his brother-in-law: "When you began these experiments," said he, "we all thought that you were going to succeed at once, and that you were on the eve of a great discovery. We have watched you and sympathize with you, but your friends here have seen that you are breaking down with overwork. And besides, I must tell you frankly that with your young family it is unjust to them that you continue in this way. You have no idea what it costs you to support your hospital, now for over three years,

and my advice is to give it all up." His answer came quickly and to the point: "My dear brother, if I live I am bound to succeed. I am as sure that I will carry this thing through as I am that I now live. I have done too much already. I am going on with these experiments to the end, it matters not what it costs, if it costs my life."

The destiny of discovery forced him against many apparently overwhelming obstacles to finally fulfil his mission. Thus a backwoods doctor of Alabama, struggling for his daily bread, hampered by sickness, working for the work's sake, his ardor glowing in the very ashes of his hope, with desperate cases forced upon him, compelled to follow in a given line, and conscious of a duty he owed to his poorest patient, was ever busy in his long and lonely drives in devising the newer means of relief. Turning to account a trivial circumstance in the treatment of a patient, what was before a perplexing problem became a solved discovery. A new method of operating was thus suggested, and with an almost overpowering enthusiasm in the possession of the principle he eagerly put it to the test. His first operation was upon a female slave. It failed, as did others upon similar subjects. But there was enough of encouragement in each to prick his ambition and spur his purpose. He must have suitable means to the end, so he equipped a little hospital of his own, and with the humblest of poor patients accomplished the greatest of triumphs.

The stitches used in his operation were necessarily so deeply placed that they could not be securely tied, and were themselves a source of infection. And then another step was taken. He had been lying awake for an hour wondering how to tie the suture, when all at once an idea occurred to him to run a perforated shot along the string, and when the suture was tightened to compress the shot, thus making the knot secure. He became so elated with the discovery that he lay there until morning performing in imagination all sorts of operations upon the patients in his little hospital. But the shot did not answer every purpose, for the silk of the suture still made union impossible. Just at this time he was walking from the house to his office when he picked up a piece of fine brass wire. "A wire is the thing," said he. A neighboring jeweller made him a fine wire of silver, and with it the thirtieth operation was performed upon the long suffering yet hopeful slave and the principle was forever established.

These incidents are merely sketched to present an outline of some parts of his character; how the greatest ending may have the most insignificant beginning. Whenever a great discovery is to be made the idea of it compasses the individual round and about, it possesses him by day and by night, at all hours and in all places, until the misty conjectures form the rainbow of promise, which frames the prospect of a world beyond. Thus Sims found fame waiting with her chaplet. From little things to great ones is the lesson of every invention. With Sims all the successes of his great operations hinged not only upon the wide utility of the famous instrument now inseparably associated with his name, but upon the accidental suggestion of a cast-off suspender wire.

So also the little hospital maintained by himself from the limited income of a poor, sickly, and hard worked practitioner, with its beds occupied by bondwomen, was the germinal conception of the present Woman's Hospital in this city, the only institution of its kind in the world, and an eternal monument to the ardent zeal and lofty purposes of its brilliant founder. Thus while here the statue preserves the memory of the good man, of the faithful worker, of the great inventor, of the broad philanthropist, the Woman's Hospital becomes for him and all of us an ever living principle, extending its charity, widening its influences, perfecting scientific skill, and fulfilling its divine mission of alleviating suffering and saving the lives of waiting generations of stricken womanhood.

But Sims was not only a leader in his own department but was always ready to devise new methods of treatment in the broader domain of general surgery. As a striking instance of this he was the first to boldly advocate the operative invasion of the abdominal cavity for gunshot wounds of that region. When the lamented Garfield was shot, Dr. Sims, in a cabled interview from Paris, advised that such an exploration should be made. Astonishing as it was, and as much criticism as it then provoked, it would be the first of all expedients at the present day.

But I must not dilate on points that will be more fully touched upon by the distinguished speaker who is to follow me.

Suffice it to say that every man having his place, Sims has found his. If brains, opportunity, environment, and energy fit him for great things, he is singled out as a memory of good accomplished, as an emulation for kindred spirits, as an exponent of the progressive idea, and as an acknowledged benefactor of his race. The realization of such a position for Dr. Sims is manifest in the reverential duties of this hour, which consign his lovable memory to the heritage of a grateful humanity.

DR. J. MARION SIMS—THE FATHER OF MODERN GYNECOLOGY.

Being an Address Delivered October 20, 1894, in Bryant Park, New York, on the Unveiling of the Statue of Dr. J. Marion Sims.

By PAUL F. MUNDÉ, M.D.,

NEW YORK.

Mr. Chairman, Ladies, and Gentlemen: You have heard from my distinguished friend, the preceding speaker, who and what manner of man Dr. Sims w s. To me has been delegated the honor of enlightening you as to the reasons why he was selected for the peculiar distinction of having a statue erected to his memory. I say "peculiar distinction" because, while in our parks and squares are found the statues of soldiers, statesmen, poets, merchant princes, and clergymen, nowhere until to day, so far as I am aware, does there stand a statue of a physician. There have been several public monuments and busts erected to prominent physicians in other cities, notably a monument to Dr. Ephraim McDowell, the discoverer of ovariotomy, in Lexington, Ky.; a bust to Dr. Benjamin Rush, in Philadelphia, and a monument to the "Discovery of Anæsthesia," the heroes of which are not mentioned in the public garden of Boston. But this statue to Dr. Sims is the first of its kind erected in this country. And why has this great distinction been awarded him? Simply and solely because, among the many eminent physicians and surgeons whom America has produced, he stands pre-eminent as the man through whose genius, perseverance, and energy a special branch of medical science and practice was so renovated, improved, and elevated as to create an era in medicine and raise America from the place of the docile and receptive pupil to the proud position of the teacher of older nations.

This claim is allowed Dr. Sims without dispute, even by those European nations who are most jealous of their own achievements in medical science.

Up to fifty years ago the special branch of medicine to which Dr. Sims devoted himself, as soon as sufficient opportunity offered, had made comparatively little progress. About the middle of the present century three men in Europe, by their individual efforts, each in his own land, raised this branch of medicine to the dignity of a specialty, and placed it on a sound scientific basis. These men were Simpson, in Great Britain, Récamier, in France, and Scanzoni, in Germany. But in spite of their efforts the treatment of these diseases advanced but little, and the one needful factor, the knife, was rarely used. Then, like a meteor, appeared the genius of Sims! In the Southern town where he had for many years followed the practice of a successful general surgeon, as my predecessor has already stated, accident caused him to stumble

on a method of operating and curing a hitherto practically incurable injury. Strange to say, the instrument which enabled him to achieve this success, and which remains indelibly associated with his name, owed its origin to the happy thought of a bent kitchen spoon! An ordinary man would not have grasped the situation; but the genius of Sims at once comprehended the immense value of his discovery, and led him on to improvement after improvement, until the whole procedure was perfected.

The field of Montgomery, Ala., then became too narrow for his ambition, and in 1853 he came to New York. His one great object here was to establish a hospital for the exclusive treatment of the diseases peculiar to the female sex; and long and hard did he work, until, after much opposition from physicians and laymen, and many a disappointment, in 1855 he was at last able to form the Woman's Hospital Association. On the opening, in 1856, of a temporary hospital in Madison Avenue, among other speakers to commemorate the occasion, Dr. Valentine Mott, who was the foremost surgeon of his time both at home and abroad, made the following remarks: "Go on, Dr. Sims, in your work of charity and benevolence! Although no marble urn or inanimate bust may tell of your honor and renown, you will yet have in all coming time a more enduring monument; and that monument will be the gratitude of woman." The latter part of Dr. Mott's prophecy has long since been fulfilled. And to-day we are assembled to celebrate the unveiling of the statue which Dr. Mott scarcely expected to see erected.

The limited accommodations of the hospital soon proved insufficient, and after many delays funds were secured for the erection of the first pavilion of the present Woman's Hospital, at Forty-ninth Street and Park Avenue, the land for which was given by the city. Since then one other pavilion and a number of cottages for tumor operations have been donated by private citizens.

This Woman's Hospital, founded by Dr. Sims, was the first institution of its kind in the world. Its work became world-known under his teachings, and those of his colleagues, Emmet, Thomas, and Peaslee. And from its walls have issued scores of young physicians, and thousands of professional visitors, who carried what they had there seen and acquired to the four corners of the globe.

A sojourn of several years in Europe made Dr. Sims's name familiar to the medical profession abroad, and many opportunities were there afforded him of demonstrating his peculiar methods of operating. But his name became particularly well known after the appearance, in 1866, of the only book of any magnitude which he ever wrote, the originality and boldness of which aroused admiration and surprise all over the professional world. By the older physicians it was even regarded with more or less distrust and incredulity. This was particularly the case in Germany, then so very conservative in this branch of medicine, but now the boldest of the bold in her daring achievements with the knife. I well remember how, in 1867, Scanzoni, the Nestor of German gynecology, whose assistant I then was, brought a copy of the translation of Dr. Sims's book, which had just appeared, to the clinic, and emphatically expressed to me his opinion that, original and ingenious as Sims's views and methods were, he still was only an enthusiast, whose illusions were not capable of realization. And that was less than thirty years ago! And in these thirty years these very "illusions" of Sims, subject, of course, here and there, to the modifications of increased experience, have become the accepted rules of practice all over the world. It may truly be said that this book of Sims made a revolution in modern gynecological practice. The era of what must properly be called "modern" gynecology, that is, operative gynecology, dates, so far, at least, as the world outside of the New York Woman's Hospital is concerned, from the year 1866. Many of Sims's views have remained uncontested or unchanged, others have been modified, and others, again, disproved. But the fact must always be admitted that the impulse of active surgical interference given by him to the, before him, largely conservative treatment of the diseases of women, has resulted in the enormous advances which this specialty has made during the last twenty-five years.

With Sims came the revolution which upset the conservative "do little" methods, and opened wide the field of active, radical, scientific, and rational treatment by surgical means of the diseases and malformations which formerly were merely palliated or left unrelieved. As the exponent of a new system in gynecological therapeutics Sims may truly, to use the term of the clergyman who delivered his funeral oration, be looked upon as an "apostle." Without disparagement to the patient labors of previous workers in the same field, I must insist that the greatest triumphs in this specialty have been achieved since Sims first taught us how to use his speculum, the scissors, the knife, and the needle for the cure of the diseases to which he paid particular attention. J. Marion Sims may, therefore, with all propriety, be called THE FATHER OF MODERN GYNECOLOGY, and it is to this universally admitted claim that he owes the distinction of being the first physician to whose memory a statue has been erected.

The genius of Dr. Sims was not limited to the specialty with which for all time his name will be connected. Quite early in his career he wrote an article on "Convulsions in Infants" (Trismus nascentium), in which he advanced the very plausible theory, borne out by later experiences, that these convulsions could be prevented and relieved by removing the pressure exerted on the brain through the soft skull of the child by the simple plan of placing it on its side, instead of permitting it to lie constantly on the back. Again, he was among the first, if not the first, to recognize an abscess of the liver and open it by a free incision. Obstruction of the gall-bladder was also the subject of an article by him, in which he described the operation of opening that organ, and thus relieving the symptoms. One of Dr. Sims's last original achievements has already been referred to by the preceding speaker — I mean his criticism of the treatment of the wound of President Garfield. I well remember how vehemently his views were opposed by the leading surgeons of this city, who insisted that it was presumptuous for him, a surgeon in an entirely different line of practice, to offer such radical suggestions to them. But Sims's views soon gained ground, and to day, only twelve years later, the correctness of his prophetic assertion is so well recognized that any surgeon who would fail to carry out Dr. Sims's advice to at once open the abdominal cavity in case of injury by gunshot or other perforating wound, and suture the wounded organs, would be considered criminally negligent! If only one such case out of one hundred is saved by this practice, it is so much gained, since without the operation death is inevitable.

I hope I have been successful in demonstrating why a statue has been erected to the memory of Dr. Sims. It certainly is not my object to deliver a fulsome eulogy of this great man. He needs no flattery. The record of his deeds speaks for itself. His memory, and the recollection of what he has done for suffering mankind will be far more enduring than his statue or the granite on which it stands. Let his life be a shining example for us to follow!

Insolated Cholera Cultures.—Dr. Palermo, of Rome, has succeeded in producing an attenuated cholera virus by the action of sunlight. This agent does not destroy the bacilli, but modifies their biological character. Guinea-pigs inoculated with cultures which had been exposed to the sunshine for more than three and a half or four hours not only presented no symptoms of the disease but were also found to be immune, resisting inoculation with the most virulent cultures.

SOME UNUSUAL CASES OF ABDOMINAL SURGERY, WITH COMMENTS.[1]

By CLINTON CUSHING, M.D.,

PROFESSOR OF GYNECOLOGY, COOPER MEDICAL COLLEGE, SAN FRANCISCO.

In January, 1893, I was asked to see the wife of a medical man, who had been suffering for several years with occasional attacks of fever accompanied by a disturbed condition of the digestion and by marked emaciation. The attack lasted from six to ten weeks, the temperature varying from 100° to 105° F. Following the attack she would slowly return to her normal state of health. There was no marked pain to indicate local disease, inability to take and digest food being the most pronounced feature.

Professors L. C. Lane and J. O. Hirschfelder saw the case in consultation, but aside from a diagnosis of chronic indigestion, no decision was arrived at.

Upon examination the patient was found in no pain, much emaciated, and without distention of the abdomen. Abdominal and pelvic organs apparently normal, analysis of urine negative; heart and lungs in good condition, pulse weak. After the examination I told the husband that I was unable to form a definite opinion as to the nature of the case, but that the probability lay between a commencing tubercular peritonitis and a small collection of pus somewhere in the peritoneal cavity.

I advised an exploratory incision as the best means of settling the question. On February 4, 1893 (with the assistance of Professor Steele), the abdomen was opened in the usual way below the umbilicus in the linea alba, the hand and arm introduced, and all the abdominal organs carefully examined.

Everything was found normal except an enlarged gall-bladder, filled with gall-stones, on the right side beneath the liver. I advised the removal of the bladder with the stones.

The opening in the central line was closed, and the abdomen laid open just below the ribs on the right side, the gall-bladder drawn out and ligated close to the liver, and the whole removed.

The recovery was uneventful, the fever disappeared, and since that time there has been no recurrence of the trouble.

A question of importance now comes up. What relation, if any, was there between the gall-stones and the fever and emaciation?

If the gall-stones were the cause of the fever, it would appear to me probable that they produced a reflex irritation of the stomach and thereby an indigestion of a sufficiently severe character to account for the fever. I am the more inclined to take this view on account of a similar experience six years ago in a case where I stitched the gall-bladder to the skin and drained it after removing a quantity of calculi.

In this last case all the symptoms were at once removed by the operation. In both cases the gall bladder could not be felt by palpation, and it was not suspected that there was any fault with this organ.

In any event, the prompt relief of the symptoms, and the subsequent good health, leads me to the conclusion that the disorder of the gall-bladder was the cause of the sickness. Since the existence of the gall-bladder is not essential to the health of the individual or to the function of the liver, I believe its removal, when diseased, is better surgery than to drain it, or to secure an artificial opening between it and the pylorus.

In April, 1893, I saw, in consultation with several well known surgeons, a case of stricture of the rectum in a woman, aged twenty-eight, the mother of two children. The stricture was about a finger length above the anus, and the contraction of the gut would not permit the introduction of the first joint of the finger.

[1] Read before the Medico-Chirurgical Society of San Francisco, Cal., September 3, 1894.

The consensus of opinion was that the disease was probably malignant, and the majority of those present opposed any surgical procedures owing to the inaccessibility of the disease.

Professor Lane and myself advised an operation on the ground of the youth of the patient and the possibility of a cure, and that the real facts in the matter could only be determined by an effort to remove the disease.

On April 22, 1893, with the assistance of Drs. Stillman and Rixford, I performed Kraske's operation, which consisted of the removal of the coccyx and the lower segment of the sacrum, the breaking up of the attachments of the sigmoid flexure of the colon to the pelvic wall, the drawing the detached gut down, the removal of six inches of the gut, including all the diseased portion, leaving about two inches of the rectum next the anus *in situ*, as it was apparently healthy. The upper end of the gut was then drawn down and carefully sutured to the end next the anus, and the large wound in the back closed with silk worm gut sutures. On account of the escape of some of the contents of the bowel between the stitches, suppuration took place in a portion of the wound. A small recto vaginal fistula formed at the upper end of the vagina immediately behind the cervix; with the exception of the fistula the wound healed readily, and she was enabled to return to her home at the end of two months much increased in weight and in good general health. She returned to San Francisco in November last, when I closed the recto-vaginal fistula, which healed readily. There was left at the site of the sutures a decided narrowing of the rectum, but the stricture permitted the passage of a Wales's soft rubber bougie an inch in diameter. At this time her physician writes me that after the lapse of fourteen months her general and local condition remain excellent.

A microscopical examination of the removed specimen demonstrated that it was an epithelioma.

One who has never witnessed this operation cannot easily conceive how thoroughly the parts are exposed to view as the operation proceeds, no vessels ligated, hæmostatic forceps being sufficient. A large sponge with a cord attached was passed up into the pelvis and protected the intestines from injury.

It is yet too soon to say that a permanent cure has been made, but the outlook is good and we have at least given the patient a year of comparative health, with good prospects of a continuance.

In this case the disease was situated almost exactly in the centre of the pelvis, and could be reached through an abdominal opening only with the greatest difficulty, and from below only by sacrificing the lower end of the gut with its sphincters unless, as in this case, the opening was made as Kraske advises. Had I to deal with a similar case in the future, I would make a trial of the Murphy button for uniting the ends of the gut, as much time would be thereby saved and the shock lessened.

Mrs. G. H——, the wife of a medical man and the mother of three children, applied to me for advice regarding an enlargement of the abdomen. She was in good general health except that she was unable to stand long upon her feet without a feeling of weight, and a bearing down sensation in the lower part of the abdomen. She was about thirty six years of age. An examination demonstrated a bad laceration of the cervix and perineum. There was marked hyperplasia of the uterus, and a smooth elastic tumor in the region of the right ovary which was pronounced an ovarian cystic tumor, and an operation advised.

On February 25, 1893, the patient was placed under ether, the uterus thoroughly curetted, the laceration of the cervix and perineum repaired, and afterward the abdomen opened in the usual manner. What was supposed to be an ovarian cyst proved to be a colloid cyst growing from the retroperitoneal tissue just below the right kidney, and the inner wall of which was made up in large part of the outer wall of the ascending colon. The tumor was about the size of a child's head at term.

The wall of the sac was covered by peritoneum about the thickness of card-board. The sac was tapped, but the colloid mass had to be removed by the hand; manifestly the sac could not be removed without sacrificing, or, at least, greatly endangering, the wall of the colon, so the cut edges of the sac were stitched to the abdominal wall and a drainage-tube inserted and fastened into the abdominal wound.

There was no shock and the recovery was uneventful. At the end of a year there was still a slight discharge from the fistulous opening, and the narrow tract was syringed out with a solution of nitrate of silver, sixty grains to the ounce, and the fistula then closed. The ovaries were found to be normal. The plastic operation on the cervix and perineum had yielded a perfect result.

I report this case, for retroperitoneal tumors of this kind are uncommon, if we are to judge by the fact that we seldom see one reported in the medical journals.

The error of diagnosis is easily understood when it is remembered that the cyst was movable and was in direct contact with the ovary, and that the patient's abdomen was well loaded with fat. However, mistakes in diagnosis in abdominal diseases are so frequent that they have ceased to cause surprise.

Dr. Hennessy, of Napa, sent a woman to me February last, with a history of pelvic inflammation ending in a discharge of pus from the rectum and from the bladder. She also passed gas from the bladder, from time to time.

She was much emaciated and suffered a good deal from pain in the region of the left ovary. Upon examination an immovable and tender mass was found in the region of the left ovary, and the diagnosis was made of a pus-tube opening both into the rectum and bladder.

On March 3, 1894, assisted by Dr. Hennessy, the abdomen was opened and the diagnosis verified. The whole left broad ligament was distended and filled with cheesy pus, and the remnants of a pus-tube were in evidence. The tube was ligated with catgut and removed, and the pus cavity in the broad ligament thoroughly curetted and afterward mopped out with a mixture of equal parts of carbolic acid and compound tincture of iodine, and a rubber drainage-tube passed through from the abdominal wound into the vagina.

There is still a fistulous opening in the abdominal wall, but the patient has grown fat and hearty, and bids fair to make a perfect recovery. This case is somewhat out of the ordinary.

In this connection I would like to call the attention of the members of the Society to a practical matter of undoubted value, and which I put in practice for the first time in this case.

In order to avoid fistulous tracts caused by leaving in the abdomen silk ligatures that have become infected with pus, I prefer in pus cases to use catgut, but a serious objection to catgut is, that in handling it with wet hands, and when it is soiled with blood and pus, it becomes slippery, and when a knot is tied down in the bottom of the pelvis, I do not feel sure that it will hold.

It occurred to me that, after the catgut had been kept in sulphuric ether for ten days in order to get all the animal oil out of it and render it antiseptic, if it were put into a mixture of an ounce of common rosin to a pint of alcohol, it would preserve the catgut and make it sticky so that it would stay tied, whether wet or not.

The experiment was a success, and the catgut stayed tied, and I can recommend it as an improvement.

Two years and a half ago a patient, aged about thirty-five, brought me a letter from Dr. Henry O. Marcy, of Boston, asking me to give her such attention as might be needed. She was exceedingly nervous, and was suffering from pain in the region of the ovaries. She was a widow and had never been pregnant. Upon examination the ovaries were found more than usually sensitive, and slightly enlarged. I advised measures to improve the general health and the use of the continuous current of electricity to be passed through the ovarian region by means of large pads made of potter's clay. She did not return for treatment and I heard nothing more of her for two years. Last spring she came to my office again for advice, stating that after leaving me over two years ago, a surgeon had performed laparotomy and removed the left ovary and tube, but with no benefit to the troublesome symptoms.

Upon examination she was found to have a ventral hernia the size of a small cocoanut in the line of the abdominal incision. The right ovary was about the size of a duck's egg, and extremely tender, the right Fallopian tube was enlarged to the size of one's thumb. Behind the uterus there was what appeared to be a mass of hard fecal matter in the rectum which prevented my making a satisfactory examination, and I instructed her to go home and take a large rectal enema and to return for further examination.

Upon her return the mass was still felt in the same place and a digital examination per rectum demonstrated the fact that the mass was in the lower part of Douglas's pouch, and through the thin wall of the gut, I could make out the outline of a round flattened mass something like the end of a spool, but further consideration led me to the conclusion that it was a finger-ring, and I so informed the patient.

She then told me that she had learned since the operation that a valuable ring had been lost at the time and that it had never been found. This only confirmed me in my original opinion that the mass in Douglas's pouch was a finger-ring buried in lymph.

On May 24, 1894, assisted by Professor C. N. Ellinwood and Dr. E. W. Thomas, the abdomen was opened and the right ovary, which was a mass of cysts, and the enlarged Fallopian tube, were removed; an attempt was made to dissect out the mass in Douglas's pouch, but on account of the cartilaginous hardness and the imminent danger of making an opening into the rectum, the effort was for the moment abandoned. The fibrous sheath of the rectus muscle was next dissected free along the edge of the incision in the abdomen and, after the usual sutures of silk-worm gut were introduced through all the tissues composing the wall, interrupted buried sutures of heavy silk were used to bring together the fibrous layers that had been dissected out, and finally all the structures were brought together by the deep sutures of silk worm gut, the buried sutures being introduced to prevent, if possible, the recurrence of the hernia. The patient was then turned upon her side and Douglas's pouch laid open from below, when the gold ring with an emerald setting, as bright and clean as the day it was made, came into view, and with a pair of strong forceps and long-handled scissors was quickly removed from a firm bed of lymph where it had laid for two years. As a consequence of the dissection a rather free hemorrhage followed, and a sponge in the grasp of a long-handled forceps was left in the opening for six hours, which effectually controlled the bleeding. The recovery was slow but uneventful, and she left the hospital at the end of four weeks. I am confident she will now be restored to health.

It is of interest to know that so small a body could be detected after being in the peritoneal cavity for over two years, but this can be understood when it is remembered how thin the rectal wall is.

Had she been free of the ovarian and tubal disease, and not suffering from hernia, I doubt that the simple presence of the encapsulated ring would have warranted a serious operation for its removal. Nevertheless Douglas's pouch is one of the most sensitive points in the human body, as can be proved by passing a sponge down upon it during an abdominal operation. Other manipulations are borne without a sign of suffering, but if Douglas's pouch is touched, the patient begins to struggle.

The following case is reported by Dr. Rixford, and is a valuable contribution to the literature of abdominal surgery, for it illustrates some of the difficulties attending diagnosis, and shows what may be done in the way of exploratory incision in serious conditions, without causing untoward symptoms:

R. L. Jump, a physician, has enjoyed generally good health. On April 18th he felt perfectly well, though for ten days or so previously he had been troubled with constipation, a very unusual condition for him. During the night of April 19th, he had abdominal pain sufficient to keep him from sleeping, situated in the right iliac and umbilical regions. The pain was constant, and resembled that experienced in several similar attacks which occurred during the last three years, though it was not so severe. In one of these attacks the pain persisted a week or more. During the evening of April 20th he was slightly feverish, and more so the following evening. Sunday morning he felt well, and walked to the ferry, but by night he was feeling badly and chilly, and had a temperature of 102.5° F. by the mouth. He took ten grains of calomel and confined himself to milk diet, but did not go to bed.

The temperature came down to 99.8° F. on the 23d, to 99.5° F. on the 24th, but rose again on the 25th to 100.5° F. He took a second dose of calomel, after which the temperature fell to 99° F. On the 26th, 27th, and 28th he took long buggy rides and felt well. Friday, the 27th, the temperature was normal night and morning, and continued so for three days. During this week, from the 23d to the 30th he had no pain.

On Saturday, the 28th, he returned to the city feeling well. Sunday he felt as well as ever, and ate with relish meat and vegetables. That night he slept well. On Monday afternoon, April 30th, he began to feel badly again; he had some uneasiness in the abdomen, but ate as usual. Temperature 102° F. Next morning he took an ounce of Rochelle salts, vomiting part of it. That night he took five grains of calomel in divided doses. Temperature 103° F. He passed a sleepless night, and Wednesday morning, May 2d, went across the bay. The abdominal pain had returned worse than before. Temperature, 104° F. At times he complained bitterly of the pain, and asked for an exploratory incision.

On Thursday, May 3d, the temperature reached 105° F., followed by a remission to 103° F. Friday morning. Five grains of phenacetine brought the temperature down to 101.5° F. The pain was so severe that morphia was given. On this day there were several fluid stools, which were thought to be due to the beef extracts with which he had been fed for two days.

The rectus muscle on the right side was quite rigid, and a decided tumefaction was felt just below and to the right of the umbilicus. This point was very tender on pressure. There was moderate tympanites. One year and a half ago he had had an extensive pelvic abscess, which was incised deeply through the perineum. In view of these facts, together with the patient's request, and the history of several attacks of abdominal pain mentioned above, and the rapidly increasing severity of the symptoms, the attendants decided upon an exploratory incision, it being thought that there was present an abscess, probably of appendical origin.

On Saturday afternoon, the 5th, Dr. Cushing, assisted by Drs. Stillman, Rixford, and Huffaker, made an abdominal section through the body of the rectus muscle immediately over the tumor. The appendix appeared in the wound and was quite normal. The lower eight inches of the ileum were moderately congested, and in violent peristalsis. The mesenteric glands of this region were greatly swollen, some being as large as almonds, and of a purple color. The total mass of the glands was sufficient to be felt through the abdominal wall, and accounted for the tumor. One of the glands was shelled out for examination.

The case was evidently one of typhoid fever, in spite of the clinical history. Typhoid fever had been discussed several times before the operation, and was strongly suggested by the rapidly increasing fever and the fluid stools of May 4th, but it was excluded on considering the history of previous abdominal trouble, the period of defervescence and return to normal health, the severe pain, the excessive tenderness, the muscular spasm, the chills, and the absence of the typhoid eruption and stupor, for the mind was bright as ever.

There was considerable dark-colored fluid in the peritoneal cavity. A glass drain was inserted. The wound was closed with silk-worm gut sutures, and dressed with carbolic acid and glycerine. There was no shock following the operation, and no vomiting.

Soon after the operation delirium became profound, and continued to May 18th. It was peculiar in that the patient knew those about him, and offered rational suggestions concerning his treatment.

On the next day after the operation the patient's pupils began to dilate, and the dilatation soon became extreme. Then strabismus occurred, lasting several days. The head was retracted, and a certain degree of opisthotonos was present. With these symptoms the pulse-rate increased to 120 and 140. Subsultus tendinum was excessive. Beginning as usual in the hands, it extended seemingly to every muscle in the body; the arms and legs were thrown about, and the thoracic and abdominal muscles contracted spasmodically.

The drainage tube was withdrawn after forty-eight hours, and the stitches were removed on the fifth day, the wound having healed by complete primary union. On the sixth day, while the attendant's back was turned, he tore off the adhesive strips and opened the lower third of the wound. No evil resulted other than the somewhat delayed healing by granulation of this portion of the wound.

Tympanites was excessive at times. The typhoid eruption appeared after the operation, and was marked on the abdomen and chest, and a few petechiæ were present even on the extremities.

At no time was the diarrhœa excessive, nor was there blood in the stools. Prostration was extreme, and the discharges were involuntary for a week or more. The greatest care was necessary to prevent the formation of bedsores, and, notwithstanding the patient was turned from one position to another every twenty minutes, and air cushions and cotton rolls were used, several small bedsores did form.

The temperature, taken by the rectum, ranged from 102° to 105° F. from May 2d to 14th, when decided remissions took place, and defervescence set in. On May 21st the temperature was 99° F., and thereafter remained normal. Great distress was caused by drying of the secretions of the throat. Several times complete casts of the pharynx had to be forcibly dislodged.

The case is remarkable in a number of respects. Few cases of typhoid are accurately observed at as early a date as this. There occurred an interval of complete defervescence following vigorous purgation with calomel and restriction to a milk diet, and complete return to health for three days. After this, the fever rose rapidly but continuously for four days. Several explanations of this have been suggested; one, that the disease really began about April 19th, and that by the prompt administration of calomel it was aborted, to be lighted up afresh on too early return to ordinary diet. Another is, that the symptoms were due to an error in diet during the prodromal stage, and were relieved by the removal of fermenting intestinal contents by the calomel.

The exploratory incision yielded a number of valuable observations besides those mentioned; viz., the localized congestion, the violent peristalsis, the dark fluid in the cavity, the enlargement of the mesenteric glands early in the disease. Dr. S. M. Mouser, to whom was submitted the excised mesenteric gland, reported that Esmarch tubes inoculated from it showed only the typhoid bacillus in pure culture. This fact is almost proof positive against ulceration of the intestines having occurred, for a break in the continuity of the mucous membrane gives entrance to a great variety of bacteria with which the intestinal contents swarm. From the violence of the peristalsis in the lower end of the ileum as the coil lay exposed, the explanation of the colicky pain was evident.

The remarkably severe nervous symptoms deserve some

attention; meningitis and frightful subsultus and violent delirium, which made it at times most difficult to give the patient food; all this in a case which progressed to convalescence without the slightest evidence of intestinal ulceration, and which was followed by a rapid return to perfect health, once convalescence was established.

Dr. Jump is Assistant Demonstrator of Anatomy in Cooper Medical College, and a most enthusiastic and thorough student of his subject. Believing that he was suffering from appendicular trouble, and knowing the dangers attendant upon it, he insisted that an exploratory incision be made without delay. He said, "If I should die without operation, and it be found that the disease could have been removed by surgical means, I want put on my tombstone, 'A victim of conservative surgery.'"

THE RATIONALE OF HYDROTHERAPY.[1]

By SIMON BARUCH, M.D.,

NEW YORK.

ATTENDING PHYSICIAN TO MANHATTAN HOSPITAL, NEW YORK JUVENILE ASYLUM, ETC.

RECENTLY a professional friend suggested that, by devoting too much attention to hydrotherapy, my usefulness as a member of the profession would be impaired owing to a one-sided view of therapeutics. This suggestion has "given me pause," but upon reflection I regard it as originating in a mistaken view of the duty of the physician to his colleagues, and to humanity at large. I take it that the physician's first duty is to cure disease, his second duty, but not less important, to garner up his dearly bought experience and offer its deductions to his fellow-laborers for criticism, study, and, if worthy, for imitation.

Through all my professional life I have been more deeply interested in therapeutics than in any other branch. Hence my contributions, whether medical, surgical, or gynecological, have been to the treatment of disease. My having spent the larger part of my professional life, like many of yourselves, in village and country practice, may account for this predilection for a branch of the profession which is to-day too much neglected at home and abroad.

A young Viennese doctor recently told me that he knew nothing of therapeutics, because his teachers were engrossed in the diagnosis of living patients, and in autopsies of the dead ones, far more than in saving the former from the fate of the latter.

To search out a rationale for therapeutics has ever been my aim, because only by this means may therapeutic methods be firmly established in the minds of the profession. This is the reason that has led me to the investigation of water as a remedial measure. Here was a field that opened a valuable mine for exploration. How inexhaustible and rich this mine is, I have daily reason to observe. If I am persistent in offering to the profession the results of my explorations in this direction, the explanation rests in the fact that I have discovered the same surprising inattention to, and consequent unfamiliarity with, hydrotherapy in the large majority of the profession, which was a painful discovery in my own case. As the value of this much neglected remedy dawned upon me in a somewhat extensive experience gathered in private and hospital practice, the question presented itself: Is it not a duty to agitate this subject in the medical societies, until its merits and objections are thoroughly canvassed?

From the earliest medical times water has been applied in medicine. In his work "De Aqua et Locis," Hippocrates laid down principles in hydrotherapy which are so sound and practical, that it would be a blessing to suffering humanity were medical students indoctrinated in them to day.

[1] Read before the North Carolina State Medical Association, April 17, 1894.

The average medical man goes into practice with the idea that warmth stimulates, and cold depresses. And yet Hippocrates himself taught the reverse, which is the truth. One of the first lessons we are taught in surgery is that when a limb is frost-bitten we should avoid heat, and apply cold. The reason is obvious even to the tyro in medicine; but when this tyro becomes a full-fledged doctor, and hears the cold bath suggested in typhoid fever, he at once objects to it as a depressing agent. To overcome this prejudice, which is as deeply rooted as it is irrational, has been exceedingly difficult, even for some of the greatest intellects, and most influential physicians, whose lives and works have illumined medical history. Asclepiades, of Prusa, the bosom friend of Cicero, was a warm advocate of water. Indeed he insisted upon being called a water doctor, and he was the man who founded the school in which were equipped for practice such illustrious men as Antonius Musa, the physician who saved the lives of the Emperor Augustus and of the poet Horace; Cornelius Celsus, the bosom friend of Ovid, and also Galen. All these men remained true to and exemplified the teachings of their preceptor, applying water successfully in many acute and chronic diseases; and yet water fell from the high estate to which they had brought it. Paulus Ægeneta, the greatest physician of the seventh and eighth centuries, was the discoverer of the use of the cold douche in sunstroke. Cheyne, Huxham, and Currie, men well known in English medicine, and Hufeland, the renowned German medical philosopher, were enthusiastic advocates of hydrotherapy, as was in later times that grand teacher Niemeyer. These representative men are mentioned to demonstrate that hydrotherapy never was, and is not now, a medical fad, that it must surely be founded on correct rationale and on practical results at the bedside, if it enlisted the advocacy of such men.

When I am charged with undue enthusiasm in this matter, I am proud to be able to point to these men, and men like Ziemssen, Semmola, Charcot, Draper, and Peabody, as confrères and collaborators.

One of the reasons why water has not become fully established as a remedy despite the advocacy of able and conscientious men, is that its rationale has not until recently been studied with care and precision. To Professor Winternitz, of the Vienna University, we owe the first attempt to invest it with some scientific accuracy. As a follower and student of this clinician, I have endeavored to impress upon my American colleagues the importance of not accepting water as a remedy only upon empirical grounds.

If it is to take a permanent place in therapeutics, a place from which the whims and fancies, the prejudices and fashions of coming generations shall not again displace it, the *rationale* of its action must be clearly established.

In this essay it is impossible to furnish anything more than a brief outline. The more succinctly principles are formulated, however, the more readily they may be accepted or controverted. The *rationale* of the internal application of water will be omitted, because this is very simple and generally appreciated. That diuresis, for instance, is enhanced by free drinking of water, is a trite observation, as is the cleansing effect of stomach lavage, and intestinal irrigation.

Although the external application of water in disease has been carefully studied by capable physiologists and clinicians, it has not obtained such universal recognition among practitioners as its positive effects deserve.

The action of water upon the human organism is derived from its physical and mechanical effects.

The physical qualities of water are utilized in hydrotherapy because it is an excellent vehicle for conveying the thermic and mechanical effects aimed at.

Water absorbs and gives up heat readily; it may be used in solid, liquid, or gaseous form; it may be applied to any limited part of the body or to its entire surface.

Hence its physical property alone makes it a most flexible therapeutic agent.

Thermic agents, as is well known, affect living tissues in the most pronounced manner.

Smooth muscular fibre contracts under cold, and expands under heat, and its contractility may be entirely destroyed by an excess of either.

By the conveyance of cold or heat by means of water, we are therefore enabled to produce striking effects upon the vital processes which depend upon muscular activity. As cold and heat are irritants, their reflex effects conveyed through the nervous system also become valuable therapeutically. Applying these axiomatic principles, we find that circulation, respiration, tissue change, and heat-production may be positively influenced by the application of water as a medium of conveyance of cold and heat, that abnormal conditions of these functions may be remedied and their healthy equilibrium restored.

That the application of cold to the cutaneous surface produces pallor and cutis anserina, is a well-known fact, as is also the *rationale* thereof. The circular fibres of the cutaneous vessels, and the elastic tissue surrounding the cutaneous capillaries are contracted, and thus they are made to contain less blood. Stagnation occurs in the arterial capillaries, while the venous, being less easily contracted, remain filled; the part becomes cyanotic. If this stage be prolonged under extreme cold, necrosis of the tissues lying in immediate contact ensues. On the contrary, if the application of cold be of brief duration reaction takes place, the part is aglow.

In the first instance we have a paralysis of the inhibitory nerves, which allows the vaso-constrictors to exert full sway; while in the latter the inhibitory nerves are stimulated, and tonic contraction and relaxation ensue. The deeper vessels in the muscular tissue are more slowly affected. The local hyperæmia produced by this reaction both on the cutaneous surface and in the deeper parts, is therefore not a passive congestion, as has been too often assumed. It is not a congestion like that produced by the application of warmth, but is the result of a vital process, reaction which is the physiological sequel of the preceding depression. Admitting these trite physiological facts, you perceive that an immense field for therapeutic effect is at once opened.

The blood which is driven out of the cutaneous and muscular vessels must be taken into the general circulation, and thus produce hyperæmia in other more or less distant parts; arousing increased activity in organs whose circulation has been impaired by disease; removing the result of abnormal tissue change which the sluggish organ has been incapable of unburthening; stimulating it to more normal function.

That such effects are really produced, laboratory experiment as well as observation at the bedside has again and again demonstrated.

In a valuable essay before the recent International Medical Congress at Rome, Professor Winternitz, of Vienna, offered some practical observations upon the changes produced by thermic agencies upon the circulation of the blood and upon its composition in health. He ascertained positively that all applications of cold which involved the entire surface of the body, or a considerable part thereof, resulted in an increase of the number of leucocytes; the percentage of hæmoglobin and the specific gravity of the blood were also increased. This remarkable change in the blood was more or less enduring, its extent varied according to the technique employed, and sometimes it did not entirely disappear even after a tolerably prolonged period of observation.

Only in those cases in which no reaction ensued, as manifested by cutaneous hyperæmia, did this effect upon the blood fail.

Indeed, in such cases the erythrocytes, and often the leucocytes, also were diminished. Sometimes the red corpuscles were diminished while the leucocytes were increased.

Locally the application of cold, when followed by reaction, almost invariably increased the cellular elements, specific gravity, and hæmoglobin of the blood, while a diminution of all these ensued in distant parts. After flowing foot-baths, for instance, blood taken from the toe showed an increase, while that taken from the finger or ear lobe showed a decrease. Warmth mostly produced a diminution of the cellular elements, hæmoglobin, and specific gravity of the blood. A comparison of the composition of the latter in the normal condition of health, even showed that blood distribution is quite unequal; for instance, while blood taken from the point of a finger furnished 4,955,000 red corpuscles, and ninety-one per cent. hæmoglobin, blood drawn from the abdominal skin showed 7,366,000, and a hundred and fifteen per cent. hæmoglobin. When, after this examination, a cold compress well covered was applied so as to envelop the whole abdomen, the blood drawn from the abdominal skin and tip of toe an hour later, was found to present a still greater difference from that of the finger-tip drawn at the same time; and while the cell-elements were decidedly diminished in the latter, that drawn from the former, underneath the compress, showed an enormous increase of erythrocytes and hæmoglobin, sometimes amounting to 2,000,000 of corpuscles, and over thirty per cent. hæmoglobin.

Up to the present time all our observations upon the effect of cold compresses and poultices were conjectural and empirical. But these valuable observations demonstrated them upon a clear rationale.

That these effects may be utilized to explain the rationale of cold applications in disease, was demonstrated last year by Thayer, of Johns Hopkins University, who observed that the blood drawn from the lobe of the ear of a typhoid fever patient after a Brand bath, contained three times the number of leucocytes which resulted from a counting previous to the bath. Since this enormous increase could not be the result of new production during the fifteen minute bath, the conclusion is inevitable, in view of Winternitz's observation just cited, that the increased activity of the circulation induced by the changing anæmia and hyperæmia of the cutaneous surface resulting from the cold bath and friction, has driven these cells from their hiding-places on the outskirts of the blood-stream and elsewhere, and brought them into active service.

Thus we have a brilliant explanation of one of the most important effects of the cold bath in typhoid, of the mildness it impresses upon its course, which may be charged to the phogocytic action of the leucocytes when actively mingled with the blood-current, where they must come into living contact with Eberth's bacilli and other pathogenic organisms. How different this physiological method of stirring up a sluggish circulation is to that produced by medicinal agents, every practitioner may learn by comparing the impotence of the latter with the demonstrable results of the former. Another result of the application of cold to the periphery is the increased blood-pressure produced. The contraction of the arterial capillaries induces a more rapid flow of blood into the veins, while the deepened inspiration, which is also a well known incident of the application of cold to the surface, accelerates the circulation in the smaller vessels, causes the blood to flow more rapidly into the left auricle, the contraction of the ventricle becomes more vigorous. Thus blood-pressure is enhanced.

Cold improves the muscular tone of the vessel, increases tension, but warmth relaxes them, causing passive dilatation and loss of tone. Although both produce a hyperæmia, one is the result of reaction and is tonic, while the other is the result of relaxation and is atonic. This trite fact is sadly disregarded in practice. Its more general recognition will do much to neutralize and remove the fear of shock from cold applications in atonic conditions. Before entering into the rationale of the clinical application of these effects, the reflex action of cold and heat as irritants may be briefly referred to here. That the idea of the direct derivative action of irritants like blisters is fallacious, has been clearly shown by Naumann and others. Naumann severed all the

connections of a frog's head from its body, except the spinal cord, and then severed one leg from the body after tying the vessels (to prevent bleeding) except by its sciatic nerve. By applying irritants to the severed leg the blood in the lungs and mesentery was made to flow more rapidly; when the irritant was withdrawn it flowed more slowly. From this experiment he deduced laws which are of so much importance in the *rationale* of hydrotherapy, that I may be pardoned for summarizing them here: "The action of irritants is reflex and potent on the circulation; feeble irritants stimulate the latter, and intense irritants depress it; effects continue after withdrawal; relaxation ensues after the stimulation; cooling follows the warming effect of the increased circulation."

That the circulation of the blood in distant parts is reflexly influenced by thermic irritants, has been plainly demonstrated by the classical experiments of Max Schueller upon trephined rabbits.

Having the circulation in the pia mater directly under his eye, he found that any irritation, such as pressure upon the belly, was followed by filling of the veins.

The application of cold wet compresses upon the belly of the rabbit was followed invariably by dilatation of the blood-vessels in the pia, and increased and slowed pulsation and deepening and retardation of the breathing.

The application of warm wet compresses to the belly of the rabbit was at once followed by a contraction of the vessels of the pia, a diminution of cerebral pulsations, and a more rapid and shallow breathing.

Very hot compresses were followed by the same effect as cold compresses. And right here I may call attention to a point not sufficiently appreciated, that extremes of heat produce temporarily the same effect as extreme cold.

By dipping the rabbit into cold or warm water, *i.e.*, giving it a bath, the same effects were produced as by compresses of the same temperature.

Many other valuable points of practical interest were ascertained by these experiments, whose results are sustained by others, all tending to demonstrate that the various hydriatric procedures produce positive effects which medicinal agents are incapable of accomplishing.

It is not difficult to demonstrate that the thermic action of water upon the human organism is capable of influencing its every part and function in the most pronounced manner.

Beginning with the skin, we know that this is an organ of protection by reason of its external layer; of excretion and heat regulation by reason of its glandular and vascular supply; of sensation by reason of its harboring terminal nerve-fibres. Hence the skin is the great outpost of the human body. As a stimulant to all these functions water has long earned a well-deserved position. That by warmth or cold conveyed through it we may increase or diminish any or all of these functions of the skin, need not be enlarged upon before this audience. By reason of its action upon the glands of the skin we may enhance excretion of products of tissue-changes, as in uræmia by warm baths and hot packs; by reason of this action we may increase or diminish the heat of the body, which is regulated chiefly by giving off moisture, and which may be powerfully influenced by direct cooling of the blood as well as by reflex effects from the nerve-centres. That soothing or stimulating manifestations may be produced by warm or cold baths is also so common an observation that it requires only an enumeration in this category.

Next to these powerful effects upon the skin proper, let us consider the effect of hydriatric procedures upon the heart and circulation. The first impression of cold upon the sensory cutaneous nerves is rapidly conveyed to the brain. Rapid contraction of the cutaneous vessels ensues, causing an increased vascular tension, which is followed by slowing of the pulse. This continues so long as the individual rests, but the pulse-rate increases with continuance of high tension if exercise be taken after the hydriatric procedure. The effect of cold applications upon the respiration is to deepen and slow it; the normal frequency is, however, soon resumed; but the deepening effect continues. Hence it is wise to send anæmic and other patients requiring increased supply of oxygen, at once into the open air after cold hydriatric applications.

The influence of cold applications upon constructive and destructive metabolism is demonstrated by the increase of urinary specific gravity and of urea which ensues, and which continues several hours, as shown by Juergensen and others, also by the increased excretion of carbon dioxide, discovered by Liebermeister and Voit after cold baths. Warmth produces the opposite effect.

Having now briefly pointed out the powerful physical and thermic effects of water upon the human body, it remains to refer to the mechanical effect.

Friction alone has been shown by Pospischl to produce a great increase of heat loss. And Winternitz has demonstrated that when active mechanical irritation is combined with cold baths, the temperature of the patient is more readily reduced.

Indeed Winternitz has announced it as a law that the amount of compensatory heat increase which is incidental to all cold baths is not influenced by the absolute amount of heat abstraction, but by the degree of actual cooling of the peripheral terminal nerve-fibres which govern the production of heat by reflex action.

Mechanical irritation, as friction during a cold bath, prevents tremor and that intense tonic contraction of the muscles which always results in the production of heat. These facts are beautifully utilized in the Brand bath, whose efficiency depends not any more upon its temperature, 65° F., than upon the active but gentle surface friction.

Aside from the reflex effect produced by the mechanical aid utilized in hydriatric procedures, the actual pressure with which water may be applied enables us to vary its effects.

In a full tub bath respiration is more difficult, because of the pressure of the water upon the thorax.

The effect of a douche delivered under pressure of one or two atmospheres is stimulating to the cutaneous results at the points of impingement.

The exact experiments of Maggoira, and Vinaj[1] demonstrated that the mechanical effect of water applied under pressure of two atmospheres increase threefold the working capacity of the muscles, as mathematically ascertained by means of the ergograph of Mosso, which correctly and automatically registers muscular resistance.

The mechanical massage produced by a good douche sets diseased structures into a vibration which cannot be approached by simple manual massage. This mechanical effect is constantly utilized most effectively in feeble patients, to whose condition it may be graded and adapted.

Locomotor-ataxia patients may be greatly injured by cold baths and douches, hence in these cases we utilize advantageously the tonic effect of hot douches by combining more or less the mechanical effects of pressure, gradually increased and adapted to the case.

This brief outline of the *rationale* of the action of water upon the human organism may be fitly concluded by explaining the manner in which it may be applied therapeutically.

We have several—indeed numerous—methods of applying water externally, all of which aim to deduce some curative or palliative result from the application of those principles of hydrotherapy which have been briefly formulated under the term *rationale*.

But we are capable of applying water in the treatment of disease with greater accuracy and more extensive latitude in resultant effect than is possible from the application of medicinal agents. I do not say this in depreca-

[1] Blaetter: fuer Klin. Hydrotherapie, January, 1892.

tion of the latter, whose value no one is more ready to acknowledge than myself.

To substantiate this proposition, allow me briefly to point out that we have three elements of increasing and diminishing the therapeutic effect of water upon the organism, viz., temperature, duration, and pressure.

That the temperature is capable of modifying the effect of water is well known. A very high or a very low temperature produces destruction of tissue, while moderately hot water produces a rubefacient effect.

The difference in the effect of a bath or other hydriatric procedure at 100° F., and one at 45° F., need but to be mentioned to be appreciated, and it cannot be denied that every five degrees more or less between these two extremes must produce a different effect in the same individual.

That the duration of a bath or other procedure is capable of modifying the effect of the latter is also known.

It would be easily appreciated by the experiment of dipping one hand into water at 40° F. for two seconds, and drying it with friction ; and then putting the other hand into the same water for ten minutes, and drying with friction. In the first case we would obtain the stimulating effect with a fine glow and well filled, ruddy, cutaneous vessels ; while in the second instance we would have a shrivelled skin, of a cyanotic hue, cold and clammy, which many minutes, if not hours, of friction would be required to react from.

It may not be so evident that every second of time of exposure to a hydriatric procedure of the same temperature may alter its effect. But this is really a fact, of which anyone can be convinced by personal observation.

Pressure.—Although the modifying influence of temperature and duration is usually recognized, the effect of pressure is not so generally appreciated.

A pressure of four atmospheres driving a stream of water of any temperature through a very minute opening produces destruction of the skin upon which it impinges.

During one of the meetings of the staff of the Montefiore Home a good deal of amusement was created by drilling small apertures into the thumbs of some very skeptical colleagues, by means of the douche filiforme of Lauriat.

Driving water at the same pressure through a larger aperture will produce a rubefacient effect, while a stream of still less pressure will produce a temporary blush only.

Thus we may produce the destructive effect of a caustic, or blister, or the rubefacient effect of mustard by simply varying the pressure with water of the same temperature.

When a stream of water at 50° F. is driven upon the body under a pressure of two atmospheres, the depressing (chilling) effect of the low temperature is counteracted by the massage and friction due to the forcible impact.

The skin emerges from such an application in a glow. If the same individual be bathed by the pouring of the water over her body from a sponge, the effect would be depressing (chilling), and so much greater reactive capacity would be required on the part of the individual that an attendant would be necessary to aid it by friction.

It is plain, therefore, that we have a safe latitude of seventy degrees (40° to 110° F.) in temperature ; a safe latitude from one second to many minutes in duration ; a safe latitude up to thirty pounds in pressure, by means of which we may modify the effects of hydriatric procedures.

Besides these mathematically ascertainable elements of a hydriatric prescription we have various modifications in hydriatric technique, as baths, packs, ablutions, douches, etc., by means of which we may again render the effect very flexible.

One who has had occasion to observe this flexibility of hydriatric measures cannot fail to be convinced that no similar effect is deducible from medicinal agents.

It is difficult if not impossible (selecting a powerful remedy for illustration) to ascertain by any reliable test if there be a difference in the effect of strychnia upon the pulse, respiration, digestion, or tissue-change produced by any non-toxic dose (from say $\frac{1}{60}$ grain to $\frac{1}{20}$). I am not aware of such facts having been ascertained.

All the so-called physiological effects described by Horatio Wood and others are predicated upon poisonous doses, not upon medicinal doses.

The same observation may be made upon many other valuable agents. Unless toxic doses, or doses closely approaching these be used, there is no definite clinical or rational difference ascertainable.

Hydriatric procedures, on the contrary, are so flexible, they may be administered by such a variety of methods, that their effect may be definitely dosed, as it were, and correctly ascertained.

In conclusion, I would offer some illustrations of the *rationale* of a hydriatric procedure.

Place a patient suffering from any severe infectious disease, with high temperature, into a bath of 70° F. for fifteen minutes, practise active friction, and observe the result.

Elevated temperature, rapid and perhaps feeble pulse, shallow respiration, dulled intellect, lost appetite, concentrated and scant urinary and other secretions indidicate that the nervous system is overwhelmed by the products of infection. So soon as he enters the water he gasps. The shock and subsequent stimulus to the cutaneous surfaces are conveyed to the nerve-centres and thence reflected to the heart, lungs, and the other organs.

Observation at the bedside at once renders these effects patent. The first effect is a refreshment, an enlivenment of the cerebrum. The eyes are opened ; the face loses its apathetic stare ; consciousness returns after one or more baths ; the inspiration is deepened ; expectoration is facilitated ; the widening of the peripheral vessels and the stimulation of their coats relieve the heart ; blood pressure is increased, and the laboring organ becomes as quiet as does a sea-tossed ship in the hands of a skilled mariner. The secreting glands are aroused to activity. Moreover, the temperature is reduced, not so violently as by medicinal agents, but more definitely, more in accord with normal tendencies. In brief, all the manifestations of the disease are favorably influenced because the normal standard is slowly but steadily and lastingly approximated under the influence of repeated judicious bathing.

Even the most exacting demands of the most recent ideas are met by this treatment.

Metchnikoff has shown by his interesting studies that inflammation is the phagocytic reaction of the organism to an irritant. Cells are phagocytes, hungry to devour any toxine or microbe that may find entrance into the blood.

We may successfully aid the system in this " reaction against toxines " by endowing its main vitalizing agent, the nerve-centres, with vigor, by furthering elimination from the skin and kidneys, by removing hyperæmia of the organs, and facilitating the passage of phagocytes into the tissues ; but more especially by rendering the blood more alkaline, and thus more favorable to the phagocytes.

A lack of recognition of these principles involved in the Brand bath in typhoid fever leads to disappointment and disaster.

If, for instance, the temperature and duration are not properly adapted to the case, the shock and subsequent stimulus are modified ; if the frictions of the surface are omitted, the widening of the peripheral vessels is prevented and cyanosis will result, instead of the ruddy hue of the skin, with consequent depressing effect upon the heart. The latter, instead of being aided by the tonic widening and responsive elasticity of the cutaneous vessels, will remain contracted, and thus embarrass the heart.

Collapse ensues, with feeble pulse, Cheyne-Stokes-like breathing, an effect so rare after the application of this bath according to its correct *rationale* that I have never

seen it, but an effect of which we often hear, in discussion, attributed to the cold bath, instead of its improper application.

That there is need for a good deal of missionary work on this subject I have frequent opportunity of observing. As an example, allow me to briefly cite a case in point. Two months ago I was asked to see, in consultation with an intelligent and experienced colleague, a child of two years, in the latter part of the third week of scarlatina. Desquamation was proceeding. The child was suffering from enormous cervical glands, jactitation with partial stupor, very high temperature, feeble pulse—in short, a clear case of sepsis. The attendant recited the difficulty of controlling the temperature by aconite, phenacetin, quinine, and concluded with the statement that even baths, against which he claimed to be prejudiced, had proved ineffectual because the child collapsed in them.

On inquiry I learned that the baths were applied fifteen minutes, beginning with a temperature of 110° F., and reducing gradually to 80° F.! If a correct *rationale* had been followed, such a bath would not have been ued

The object in view was to lull the patient to rest, to reduce temperature and improve the heart's action. That a temperature of 110° F. would produce the opposite effect it would seem patent enough even to one who has not studied the *rationale* of hydrotherapy.

But to disturb a child in this condition by the splashing and noise necessary to reduce the bath to 80° F., to allow water at such a low temperature to come into contact with a tender partially denuded skin, even by slow degrees, is entirely opposed, as you will perceive, to the *rationale* I have offered. A bath of 95° F. for eight minutes fulfilled the indications effectively.

A few days ago a phthisical patient in my wards at the Manhattan Hospital, who was receiving considerable benefit from a dry pack, followed by ablutions at 80° F., reduced daily until 60° F. was reached, was asked how he liked the cold ablutions. His reply was that he liked the treatment, and that he had received it in another hospital where they had even put him in tubs of ice-water.

Patients subjected to improper hydriatric procedures fortunately do not die from them, they do not even suffer materially in most cases, but the remedial effect is neutralized, if not entirely thwarted, by a disregard of the true *rationale*, and thus hydrotherapy comes into unmerited disrepute.

This is my chief reason for bringing this subject to your attention. I ask you to give the same clinical study to the remedial uses of water which you have devoted to the study of medicinal agents (not, however, to the neglect of the latter). I ask you not to condemn this valuable agent until you have tried it fairly according to the principles which are briefly pointed out in this paper, and which will amply repay more elaborate investigation. Having mastered these principles you will find that the clinical application of water will afford you not only an auxiliary to the ordinary treatment of diseases, especially those which have become chronic and intractable, but in many desperate cases it will prove a last but effective resort.

In chlorosis that has resisted iron, in the various obstinate digestive troubles, in phthisis, chronic rheumatism, and neuralgia, in neurasthenia and other functional neuroses, in the faulty nutrition of many organic diseases, I have been able to confirm the opinions of Draper, Semmola, Erb, Charcot, Leyden, and other clinicians, that we have in hydrotherapy an agent of great power which is not sufficiently recognized by the profession. I have come to regard no case as hopeless until a judicious and methodical application of water has proven ineffectual.

Dr. Heinrich Paschkis has assumed editorial management of the *International Klinische Rundschau* of Vienna, formerly edited by Dr. Arthur Schnitzler.

THE ACTION OF ELECTRICITY ON THE SYMPATHETIC NERVOUS SYSTEM.[1]

By A. D. ROCKWELL, M.D.,

NEW YORK.

THE influence exerted by electricity upon the sympathetic system of nerves is a subject of exceeding interest. There can be no question in regard to the phenomena that attend the direct applications of either current in physiological investigations, and it is not surprising that those who first witnessed these phenomena regarded them as significant of the possibilities of this agent in the treatment of diseased states of the central nervous system. Unfortunately, external or percutaneous applications of electricity—galvanic or faradic—failed in great measure at that time to substantiate the hopes entertained, and the therapeutic results in those cases where the sympathetic was supposed to be involved, were altogether unsatisfactory. We do not have to seek far for the causes of this failure. They are to be found in an incorrect appreciation of the relation of electricity to the human body, based upon an imperfect knowledge of the physics of electricity, and the lack of suitable appliances and instruments of precision.

In view of the wide field opened to us, in case it can be demonstrated that in therapeutic doses electricity can be made to appreciably affect the deeper nerve structures, it seems to me most desirable to gather together some of the facts bearing upon this interesting question. This seems to be the more necessary because there are many who honestly doubt the possibility of electrically stimulating any part of the central nervous system by ordinary percutaneous methods of application. Certainly no one who has witnessed an execution by electricity can doubt its power to directly influence the most distant organs; and if fifteen hundred volts will instantly paralyze every bodily function, would it not be strange if fifty volts, or one-fiftieth of the power necessary to kill, possessed no influence on the brain and the deeper-seated nerve-structures? Reasoning from analogy, the facts are all in favor of this probability, for in the administration of drugs far less than one-fiftieth of the dose necessary to destroy life is often productive of appreciable therapeutic effects.

We possess very few pathological facts in support of the sympathetic origin of disease, and therefore, in studying this question, and the one that I am about to briefly consider, viz., the action of electricity on the sympathetic, it will be instructive to refer, 1, to the effects of electrization on the exposed sympathetic, and to a few of the ascertained facts in regard to the influence of the sympathetic on the functional activity of various organs; 2, to ascertain phenomena observed after percutaneous applications in the neighborhood of the sympathetic; 3, to clinical observations illustrating the effects of applications of electricity to the neck in certain conditions supposed to be dependent upon disorders of the sympathetic.

Beginning with the original experiments of Claude Bernard as far back as 1832, we find that division of the sympathetic causes a multitude of phenomena. The cornea flattens, the pupil contracts, the globe of the eye retracts, the palpebral fissure decreases in size, the conjunctiva reddens, and there is a very positive elevation of temperature due to a general dilatation of the vessels of the head and neck on the side operated upon. Electrical stimulation of the cephalic extremity of the severed nerve, on the contrary, causes the vessels to contract, and all the various phenomena to disappear for the time being.

The influence of the vaso-motor nerves of the eye was made evident a century ago by the investigations of Pourfour du Petit. The vessels of the iris dilate on division of the sympathetic, followed by immediate contraction when the peripheral extremity of the nerve is submitted to electrical excitation.

[1] Read before the American Electro-Therapeutic Association, September 25, 1894.

Brown Séquard, experimenting upon guinea-pigs and rabbits, by dividing the cervical sympathetic, found after the lapse of a few months an appreciable atrophy of the brain of the same side.

That the intercranial blood pressure is in some degree regulated by the cervical sympathetic, seems altogether probable on account of the anatomical relationship. The nerves of the pia mater, and those associated with the vessels of the cortical substance, are traced back to the sympathetic plexus, irritation of which causes immediate contraction of the cranial vessels. Perhaps the most conclusive experiments in this direction were made by Fisher[1] in 1875. With the aid of a hæmato dynamometer, he was enabled to show that faradization of the exposed sympathetic of a horse resulted in a constant increase of arterial pressure, as well as increased tension of the arterial walls.

Intestinal peristalsis is undoubtedly more or less under the influence of the sympathetic; the movements of the intestines in animals being arrested on irritation of the splanchnic nerve, while the thoracic and abdominal sympathetic impart accelerating influences to these movements. The uro genital apparatus also, including the bladder, the ureters, seminal vesicles, and the uterus, respond to experimental irritation of the sympathetic plexus of the abdominal cavity.

The secretory processes of the body depend largely upon the influence of the vasomotor branches of the sympathetic, the secretion of the gastric juice being carried on automatically by the ganglia situated in the walls of the stomach. The nutrition of the mucous membrane must in a measure be dependent upon this system of nerves, since extirpation of the solar plexus is followed by hyperæmia, extravasation of blood, and ulceration. Stimulation and extirpation of the abdominal sympathetic plexuses, affect the intestinal secretion, the evacuation, and the general nutrition of the intestines. The vasomotor nerves of the liver are derived from the sympathetic. These nerves have their origin near the floor of the fourth ventricle of the brain, entering the sympathetic, and thence with the blood-vessels pass to the gland itself. Puncture of these vasomotor nerves produces paralytic dilatation of the vessels and the production of sugar—the same results that follow puncture of the floor of the fourth ventricle itself. These effects were supposed to be produced by stimulation, but the experiments of Cyon and Aladoff, in 1871, made it quite evident that the appearance of sugar in the urine came not from stimulation, but from paralysis, of the sympathetic. Not only did they find that removal of the cervical ganglia of the sympathetic was invariably followed by diabetic symptoms, but also when the nerve-branches, central and peripheral, with which it is connected, are divided. Interference with the function of the sympathetic affects the excretion from the kidneys in more ways than the elimination of sugar. Albuminuria, hæmaturia, with quantitative and qualitative changes in the urine, together with disturbances in the nutrition of the kidney and suprarenal capsules, have often been observed. The spleen and the entire genital apparatus also have intimate connection with the sympathetic through their nerve-supply, irritation of which produces marked circulatory disturbance in both the spleen and penis.

Burckhardt[2] and Ziemssen's[3] experiments upon the dead body indicate the possibility of directly affecting the cervical sympathetic through percutaneous application of the galvanic current. They thrust partially insulated needles into the sympathetic from behind, connecting their free ends with a sensitive galvanometer. Electrodes connected with a galvanic battery were placed, one near the angle of the lower jaw, and the other at the manubrium sterni, and when the circuit was closed the movements of the needle indicated the action of an electric current on the nerve itself.

[1] Deutsches Archiv fur Klinische Medicin.
[2] Ibid., 1878.
[3] Die Electricitat in der Medicin.

Again, if one electrode, the anode, is placed at the manubrium sterni, or in the neighborhood of the cilio spinal centre, and the cathode at the inner border of the sterno-cleido muscle, a little below the auriculo-maxillary fossa, and a current of sufficient strength employed, the pupil of the same side may be made to instantly dilate on closing the circuit, followed by a gradual contraction. The difficulty of demonstrating this phenomenon in most persons is due to their susceptibility to the action of the current, many suffering from extreme vertigo, and even nausea and faintness, before the current is sufficiently strong to produce contractions visible to the unaided eye. By the aid of the pupillascope, however, it has been found possible to detect these changes in the eye with even exceedingly weak currents. Changes in the pupil so slight as to escape direct observation, are yet associated on the retina with what are called dispersion circles, the character of which accords with the degree of contraction or dilatation of the iris. While it seems to be entirely probable that the dilatation and subsequent contraction of the pupil on closing the circuit, are due to the action of the current on the sympathetic pupillary branches, nevertheless, it is impossible not to take into consideration the fact that reflex influences are potent factors frequently in the movements of distant parts, and therefore in these experiments there is some ground for the claim that pupillary changes may be reflex in character.

The circulation is unmistakably influenced by strong and prolonged applications of electricity to the neck and neighboring parts, and the reason why the test fails experimentally in so many cases, is because of the inability of the ordinary subject to endure the necessary strength of current.

In the many tests that I have made to determine whether or no it is possible to get any appreciable electrical effect upon the sympathetic by percutaneous applications, I have occasionally met with interesting and suggestive results. Everyone who has much to do with the medical application of electricity, is aware how varied is the susceptibility to its effects. The two following records are interesting illustrations of this fact, and of the probability of direct electrical stimulation of the sympathetic by external applications.

Case I.—Male, aged thirty-one, with a normal pulse of 75. An electrode of plastic sculptor's clay, 3 ctm. in diameter, and connected with the positive pole of a galvanic battery, was applied to the hollow just above the clavicle, at its juncture with the sternum. The current was gradually increased to 75 m., which caused a decrease in the frequency of the pulse of ten beats in less than one minute, and this decrease in the rapidity of the heart's action continued so long as the electrodes remained in position. On removing them the pulse would almost immediately increase to its normal frequency, and also the respiration, which was invariably affected equally with the pulse. The results in this case clearly depended for the most part on stimulation of the inhibitory fibres of the pneumogastric, and the fall in the heart-beats may have borne no relation whatever to the sympathetic system. None the less, however, was the test of value in demonstrating the possibility of influencing the deeper-seated nerve-structures by currents of sufficient strength. Only occasionally can a person be found who can endure such a strength of current through small electrodes, and placed as indicated; but few opportunities, therefore, have been afforded of getting so striking a result. I have observed the good effects of electricity in chloroform poisoning, but not through the use of the galvanic current, the tendency of which is undoubtedly to inhibit the action of the heart. The induced current, as ordinarily applied, certainly does not affect the inhibitory fibres controlling the action of the heart, and its undoubted influence over respiration must be ascribed to the action of the current on the accelerating fibres of the vagus and sympathetic that refer to the respiration. The induced

current of electricity, therefore, does good in chloroform narcosis in increasing respiratory activity, the strength of current necessary for this purpose being insufficient to materially interfere with the movements of the heart through its action on the inhibitory fibres of the vagus that control it.

The next record, as compared with the first, illustrates how varied are the susceptibilities of different individuals to the effects of electricity.

CASE II.—Female, aged twenty-three, with a normal pulse of 72. Electrodes of the same size and applied as in the previous case; and yet 15 to 20 m., was all this patient could possibly bear without a tendency to faintness and nausea. Confining the strength of the current to a point below the production of these symptoms, it was most interesting to note its very positive effects upon the pulse. This effect was not immediate, as in the former case, when currents of far greater strength were used; but by keeping the electrodes in position for several minutes, it was found that the pulse would invariably sink to 65. I have at the present time under observation a young man aged twenty-two, with a remarkably torpid circulation. His pulse seldom rises above 48, and under the influence of a strong current it can at will be reduced to 43. If these effects upon the pulse are due, as is probably the case, to a stimulation of the inhibitory function of the pneumogastric, it is only an additional argument in favor of electrically influencing the sympathetic; for if the vagus is influenced by percutaneous applications, the sympathetic ought also to be affected as the threads of current pass from pole to pole.

Exophthalmic Goitre.—In support of the sympathetic origin of exophthalmic goitre, we have the well known fact that division of the cervical sympathetic in animals is followed by a train of symptoms that are most suggestively in accord with those of Basedow's disease, and the further fact that in a certain limited number of cases pathological anatomical changes have been found in the sympathetic after death.

Among the many special phenomena that point to this causal relationship, there is one of special interest referable to the eye. It is a common observation that ordinarily, when the plane of vision is altered, the movements of the eyeball upward or downward are closely followed by the upper eyelid. In exophthalmic goitre the eyelid does not follow the movements of the eyeball, and the cause of this deficient mobility Von Graefe ascribed to innervation of Muller's unstriped ocular muscles, which receive their nerve-supply directly from the sympathetic nerve. To my mind, however, one of the strongest arguments in favor, not only of the sympathetic origin of this disease, but also of the possibility of directly influencing the sympathetic by the galvanic current, relates to my personal experience in the treatment of exophthalmic goitre.

I published in the New York MEDICAL RECORD of September 30, 1893, an article on the treatment of this disease, based on 45 consecutive cases, in which the results of electrical treatment were so pronounced in a large proportion of the cases, that, admitting the disease to be dependent on sympathetic disturbance, there can be little question but that these results were in the main due to the action of the current upon the sympathetic. The following case furnishes very strong evidence in support of this assertion.

CASE III.—Miss C——, aged twenty-three, came to me in September, 1893, with the three cardinal symptoms of exophthalmic goitre quite distinctly present. The pulse was 115, the eyes prominent, and the thyroid considerably enlarged. These symptoms had been coming on for about three years, and in connection with the protuberance of the eye, the patient called my attention to a marked dilatation of the pupil of the right eye, which she only observed a few weeks before, and shortly after the occurrence of a feeling of pressure in the neck and a slight feeling of suffocation. The tumor was highly vascular, made of tortuous blood-vessels, and not of firm thyroid tissue.

It was evident that the oculo-pupillary fibres of the sympathetic were involved, and that the irritation causing the well marked and persistent mydriasis must be due to the pressure of the enlarged blood vessels upon the sympathetic. Applications of the galvanic current were soon followed by some appreciable amelioration of the symptoms, but the point most interesting was the fact that the pupil began immediately to decrease in size, and became entirely normal, before there was any change in the prominence of the eyes, the rapidity of the pulse, or even in the size of the thyroid itself. Such pressure, however, as had been sufficient to produce this oculo-pupillary symptom had been relieved, and this could have only come through a contraction of the enlarged vessels, and through treatment having a direct influence over the sympathetic.

We have in this case an illustration of a simple irritation as distinguished from a paralyzed condition of the sympathetic. I am aware that damage to this nerve more frequently produces a paralysis with myosis than a simple irritation with mydriasis, but it has been shown that those causes that produce ultimately a paralysis of the sympathetic, may primarily induce only irritation. A case was reported by Ogle of an abscess of the neck which, as it enlarged, occasioned extreme dilatation of the pupil; the dilatation disappearing after a quiet sleep. Subsequently the pupil became much contracted, but upon the abscess being opened and the pressure relieved, the pupil became normal. The explanation offered of these phenomena was this: The inflammatory exudation and suppuration associated with the development of the abscess, at first stimulated the pupillary fibres, producing mydriasis. The secondary or prolonged effects of the compression, however, lessened the conducting power of the nerve fibres, inducing paralysis and myosis. In the case which has just been related the condition was primarily one of irritation, which might have merged into one of paralysis, had there been any material increase in the arterial dilatation.

Unilateral Hyperidrosis.—Unilateral hyperidrosis is not of such rarity as to entitle it to special comment, without it offers points of therapeutic or pathologic interest. Notwithstanding the well-known experiments in which severance of the sympathetic in horses produced a profuse unilateral perspiration, the pathology of this somewhat unique symptom has not been definitely settled. Cases of unilateral hyperidrosis, many of them, indicate not the slightest evidence in other respects of sympathetic disturbance, but a few cases have been placed upon record,[1] which seem, with considerable certainty, to point to paralysis of the sympathetic as, in some instances, the cause of persistent unilateral hyperidrosis. A case reported by Seguin[2] indicated on examination no change to the naked eye, but microscopically there seemed to be an abundant granular pigment filling the ganglionic cells, although both sides were alike in this respect. A case reported by Ebstein[3] revealed more definite and pronounced pathological changes. The patient, a man of sixty, suffered from paroxysms of angina pectoris, accompanied by hyperidrosis of the left side. Microscopic examination of the ganglia of the left sympathetic revealed varicose and dilated vessels, with perfectly normal nerve tissue upon the right side. Ebstein therefore claimed that hyperidrosis depended on a temporary or permanent compression of the sympathetic nerve-elements, resulting in paralysis.

The case that I herewith report is of value, not only because of the associated symptoms indicating an involvement of both the vasomotor and oculo-pupillary fibres of the sympathetic, but because the results of treatment gave further evidence of the sympathetic origin of the disease.

[1] Eulenburg & Guttman: Sympathetic System of Nerves, p. 58.
[2] American Journal of the Medical Sciences, October, 1872.
[3] Virchow's Archiv, 1875, Bd. lxii., p. 425, quoted by Eulenburg and Guttman.

Case IV.—Mr. M——, aged sixty-five, was referred to me by Dr. John H. Demorest, of New York. This patient was greatly enfeebled, was suffering from digestive disorders, and in addition I found a profuse unilateral hyperidrosis, involving the right side of the head, face, and trunk of the body, the right arm, and to a less extent the right leg and foot. While the left side was abnormally dry at all times, the right was always moist; the median line, front and back, sharply defining the two conditions. The right ear was also hotter and redder than its fellow, and with it was associated a persistent congestion of the conjunctivæ. In addition to these vaso thermic phenomena there existed a considerable degree of myosis, suggestive of paralysis of the oculo-pupillary as well as the vasomotor fibres of the sympathetic. This patient was subjected to thorough and persistent treatment by both the galvanic and faradic currents of electricity, and with results of the most pronounced character. The patient did not regain permanent health, nor strength, and, indeed, finally died from exhaustion; but the hyperidrosis lessened very considerably after each treatment, and would occasionally almost entirely disappear, while, in an equal degree, the pupil dilated and the heat and congestion decreased. On the whole, it seemed to me a very satisfactory test of the efficiency of electricity in directly influencing the function of the sympathetic.

Hemicrania.—The following case of hemicrania is still another interesting example of the probable part played by the sympathetic as a causative factor in disease, and strengthens one's belief in the power of electricity to directly affect the sympathetic.

Case V.—Mr. F——, aged thirty-three, had for some years been subject to frequent and violent attacks of right hemicrania. Whatever tended to raise the blood-pressure in the head greatly aggravated the distress. During the attacks the temporal artery became hard and tense; the face pale and the eye sunken, with a narrowing of the palpebral fissure. The patient had intermittent attacks of nausea, with alternations of unnatural dimness and clearness of vision; while as the paroxysm subsided, the face became abnormally red, and both the eye and ear considerably injected. The initial and prominent symptoms, such as the condition of the temporal artery, the paleness of the face, and the depressed and altered condition of the eye, all pointed to a persistent contraction of the muscular coats of the vessels on the side supplied by the cervical branches of the right sympathetic nerve; while the nausea and sudden changes in the character of the vision indicated contemporaneous changes in the intra-cephalic blood-pressure, due to repeated changes in the calibre of the small blood vessels. We find also a rational explanation for the secondary injection and increased heat of the face, eye, and ear, in the changes from a condition of tetanic spasm to a state of relaxation and dilatation of the overstrained vessels. Such a very positive condition of tonic vascular spasm could be due only to some disturbance of the sympathetic nerves.

I refer to the treatment of this case by the galvanic current, not because of any very remarkable therapeutic effects, for all efforts were futile in entirely overcoming these paroxysmal attacks, but as an evidence of the possibility of directly affecting the sympathetic. A current strength of fifty m., when applied to the neck during a paroxysm of pain, gave appreciable relief so long as the treatment was continued, and for a considerable time thereafter. No sooner were the electrodes in position—one on the cilio-spinal centre, and the other below the auriculo maxillary fossa, and the current gradually increased until 20 m. were registered, than the pain abated, and as one electrode was moved down toward the manubrium sterni, and the strength increased to fifty m., there was still further relief and change of symptoms. The face on the affected side, which was so pale and sunken, became almost normal in appearance, and appreciably warmer, the ear redder, while the affected eye opened widely; the eyeball standing out as prominently as its fellow. This treatment was often repeated, but with only temporary relief. The tendency to these attacks of hemicrania was not materially weakened, as had been somewhat confidently expected on account of the very marked immediate effects of the treatment.

Progressive Facial Hemiatrophy.—From the fact that this disease has been known to follow mechanical injury of the cervical sympathetic, it seems not improbable that it may be related to the sympathetic, rather than to the trigeminus, with its vasomotor nerves of nutrition.

While, so far as I am aware, there are no recorded cases of cure, or even material benefit, following galvanization of the sympathetic, yet Brunner reports a case where the galvanic current caused a reduction in the rapidity of the heart's action, dilatation of the pupil, with redness and perspiration of the face. Eulenburg and Guttman also report a case of this kind, where galvanization of the neck caused a reddening of the affected side of the face that lasted some hours.

In confirmation of these reports, I recall a case seen some years ago at the clinic of the New York Post Graduate School, in which strong galvanization of the neck quite perceptibly increased the heat and redness of the atrophied side.

Progress of Medical Science.

Treatment of Peripheral Neuritis.—Professor Leyden believes that in the case of neuritis following acute specific diseases, care during convalescence as to nourishment, rest in bed, and avoidance of over-exertion contribute to prevent its occurrence. "Etiological treatment" (removal of the cause) in neuritis due to alcohol or lead, and treatment of the primary malady as in diabetes, is of the first importance. There is no specific remedy for multiple neuritis, and treatment by drugs does not play a very important part. Owing to the fact that rheumatism is not infrequently an element in the etiology, salicylate of sodium and other anti-rheumatic drugs had been used, without producing any good results in the majority of cases. Iodide of potassium was of use only now and then, and mercury was of doubtful value. Antipyrin, phenacetin, exalgin, euphorbia, and methylene blue were sometimes of use for the relief of pain, but it was often necessary to resort to morphine, chloral, sulphonal, etc. Strychnine, formerly much used, but lately fallen into the background, deserved to be tried; by increasing the excitability of the affected muscles it favored the return to normal function and nutrition; it ought especially to be resorted to in progressive cases in which the respiratory movements were threatened. Leyden prefers to use it as a subcutaneous injection, gr. $\frac{1}{10}$ to gr. $\frac{1}{50}$ twice daily. Massage and baths were valuable auxiliaries which were indicated, especially the latter, in the later stages of the disease. General hygienic treatment was of much importance. Rest—as a rule rest in bed—was of the first importance in the early stage; in the later stage, feeding. Finally, in the latest stages of all, moral suasion, rousing the patient's latent energies, was often of great value. Passive movements and encouraging the patient to make active movements, were generally attended with better results than massage in this stage. Electricity, formerly used too much, was now used too little, but its usefulness was greatly limited by the fact that in many cases the pain caused was too great to permit the treatment to be continued.—*Berliner Klinische Wochenschrift.*

Our Present Knowledge of the Cure of Malaria by Means of Quinine.—According to Professor Binz so long as twenty-six years ago he opposed the then generally accepted theory that the curative action of quinine

in malaria is developed through the nervous system, and propounded the theory that quinine in all probability acts as a protoplasm poison on the pathogenic micro-organism, at that time undiscovered, which is at the root of all paludism. It has now been discovered that all forms of malarial fever are brought about by organisms of the genus amœba, which penetrate the bodies of the red blood-cells, at whose expense they increase in size, finally sporulating and destroying their host. Laveran, who first discovered and described the parasite of tertian ague, also investigated the action of quinine on that organism, and found that when microscopical preparations of the parasite were treated with quinine, the vitality of the disease-germ was speedily destroyed, a fact which has been substantiated by Marchiafava, Celli, Grassi, and Feletti. The influence of quinine on the malaria parasites has also been studied by examining the blood of malaria patients before and after the exhibition of the drug. In this instance the investigations of Laveran, Romanoffsky, Bacelli, Golgi, Marchiafava, and Bignani established the fact that the parasites were killed by the quinine absorbed into the blood.

Dr. Mannaberg, who has recently investigated this question in the malarial districts of Dalmatia, Istria, etc., finds, among other things, that about three hours after the exhibition of from seven to fifteen grains of quinine, the amœboid movements of the amœboid form of the parasite of tertian ague slacken to a very perceptible degree, and that after a lapse of a further period of three to six hours, the number of parasites in the blood of the patient greatly diminishes, while many of those still left are torn and mutilated. On the full-grown parasite of tertian ague quinine either produces a complete cessation of all movement in the pigment, whereby the parasite acquires a glittering, cloddy appearance, as though coagulation had set in, or else dropsical swelling is set up, or, finally, the parasite falls to pieces. Shortly after the exhibition of quinine, medium-sized parasites of tertian ague develop intense activity. It appears that quinine possesses a stimulating action before causing coagulation and immobility. This phenomenon has also been observed by Bacelli. According to Golgi, the medium-sized parasites of quartan fever acquire a glittering appearance and tendency to shrivel when the patient receives quinine internally; the large forms, however, become distended, their pigment exhibits lively oscillatory movements, and they frequently contain vacuolæ or abortive spores. About three hours after the exhibition of a dose of seven and one half grains of quinine, the nucleoli of some of the amœba of the milder forms of true quartan had either partially or entirely lost their tinctorial characteristics. After twelve hours of the treatment stainable nucleoli were hardly met with at all, most of the parasites having broken up into irregular fragments. From these and other experiments it is evident that the amœba of malaria is not only visibly enfeebled by the presence of quinine in the blood, but that its capacity for producing viable spores is greatly diminished. In those forms of malaria which are not curable by quinine that drug has no effect whatever on the parasites present in the blood. Bacelli, however, has found that many such severe forms which defy the ordinary method of treatment may be speedily cured by injecting the usual dose of quinine into a vein.

In spite of certain differences on minor points, Mannaberg and the other investigators one and all agree that quinine is a direct poison for the malaria parasite, and that the therapeutic doses employed are non injurious to the cells of the human organism. Any assistance from the nervous system in the process of cure is neither evident nor necessary. With regard to the prophylactic action of quinine, it is to be noted that the drug disappears very gradually from the blood and in an almost unaltered condition. By this means any young amœbæ and spores are kept in constant contact with the drug, and are thereby checked in their further development. As to the part played by the leucocytes, it appears that phagocytism is prominent in cases of spontaneous cure of malaria, but not when quinine is employed.—*Provincial Medical Journal.*

The Relation of Bacillus Coli Communis to Typhoid Fever.—According to Dr. Kellogg it will be remembered that in 1887 Hueppe called attention to the possible pathological importance of the colon bacillus, having found this organism in nearly pure cultures in cases of cholerine. In 1889 Roded and Roux made extensive investigations of this bacillus in relation to typhoid fever in which the conclusion was reached that the typhoid germ is a modified colon bacillus. Several investigations have been recorded of outbreaks of typhoid fever resulting from the use of the water from a common source, usually a well, from which no typhoid bacillus could be found, but the colon bacteria were present in large numbers. The claim that is made at present by certain bacteriologists is that the colon bacillus, which ordinarily possesses very little pathogenic power, can be made sufficiently virulent to produce an effect similar to that of the Eberth or typhoid bacillus.

Another interesting fact is the observation that the colon bacillus becomes increased in virulence during an attack of typhoid fever. Vallet has shown that rabbits that were inoculated with the filtrate from vaults containing excreta from typhoid-fever patients were protected to an appreciable degree against the inoculation of the typhoid bacillus. This experiment serves to explain the fact, so often noted by sanitarians, that visitors to an infected locality are more likely to suffer from the disease than the residents who are accustomed to drink the contaminated water. After certain experiments, which are too lengthy to record in full, Kellogg draws the following conclusions, based upon his own work and the results of other investigations: 1. The bacillus coli and the bacillus of Eberth are so nearly identical in their biological characters that none of the numerous methods proposed for distinguishing them can be relied upon as giving constant results. 2. The bacillus coli gives in inoculation experiments identical pathological effects with those produced by the bacillus of Eberth. 3. The bacillus coli acquires, by passing through the body of an animal, biological characters closely resembling those of Eberth's bacillus. The bacillus coli found in vaults is much more virulent than the bacillus coli of the intestines or Eberth's bacillus. 4. The bacillus coli is much more resistant than the bacillus of Eberth, and thrives in vaults, while the bacillus of Eberth quickly dies under the same conditions. 5. The study of epidemics, and the bacteriological study of waters which have given rise to typhoid fever, lead to the conclusions that the bacillus coli at least shares with the bacillis of Eberth the property of producing typhoid fever under certain circumstances, and that the bacillus of Eberth may be only a variety or modified form of bacillus coli. 6. The contaminations of milk with the excreta of cows is a possible source of infection with the bacillus coli and with typhoid fever. 7. The same care ought to be observed in the protection of water used by cows kept for milking purposes from contamination from excreta, as for that used by human beings for drinking purposes. 8. Since vaults and cesspools constitute depots in which the comparatively innocuous bacillus coli acquires malignancy and virulence, rendering it highly destructive to human life, these convenient nuisances should be prohibited by law, and the destruction or disinfection by proper agents, or conveyance to a safe distance from human habitation, of all alvine discharges, should be compulsory as one of the most important means of conserving the public health.—*Medical and Surgical Reporter.*

A New Convalescent Hospital.—Mr. Yarrow, the English builder of torpedo-boats, has recently given $600,000 to build and endow a hospital for convalescent children at Broadstairs.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

THE SIMS' STATUE.

THE dedication, in this country at least, of an heroic statue to a medical man marks an important era in medical history. Dr. James Marion Sims, dead over ten years, comes again to us in the earthly immortality of bronze and granite. He once more looks at us as of old, with gentle persuasiveness and calm conviction, the index of a life well spent, the unchangeable impersonation of a living principle. When the present generation shall have passed away, he will remain through coming seasons and fleeting years, for unborn eyes to look upon and coming tongues to speak his praise. The benediction of his good works will thrill the enthusiasm of future workers in every line of human progress. It is pleasant to think that his example can be constantly with us and continuously extend into the beyond. The lesson of his life is now written, the lovable memory of his past struggles, and the cordial recognition of his final triumphs, are new incentives for lofty purposes and noble emulation for persistent endeavor. He was the founder of a new medical faith, and his works live after him. As the father of modern gynecology, he becomes the exponent of a living thought constantly widening and progressively extending. Time has now so softened the asperities of criticism, and calm judgment has so cooled the temper of envy, that no one will now question his genius or doubt his talents. The statue as it stands is the final vindication of his faithful work, and the lasting tribute to his duty done.

It is, therefore, with no small degree of pride that the MEDICAL RECORD recalls its initiatory efforts to do him honor, and likewise does it congratulate the many subscribers, in this and other countries, who through its columns so promptly and generously contributed to the fund. The heartiest thanks of the many friends and admirers of Dr. Sims are also due to the distinguished gentlemen who have so long served on the committee, and who have so faithfully discharged the duties of their high office. In evidence of this is the statue itself, which is acknowledged by competent authorities to be the best conceived and most artistically executed of any in the city. That the contributors to the fund, and the members of the profession throughout the world, may judge of this fact for themselves, we have the pleasure of presenting in this number of the MEDICAL RECORD a full-page illustration of the statue as it now stands in Bryant Park.

In completing the history of the monument, it is proper to add that the receipts and expenditures on account of the fund, submitted to the committee by William Wood & Co., treasurers, have been duly audited and found to be correct. And thus endeth our loving part in memory of an old friend.

COLLEGE ATHLETICS.

AT a recent meeting of the Boston Society for Medical Improvement, Dr. W. M. Conant read a paper on the "Educational Aspect of College Athletics," and it was discussed at length by a number of prominent physicians and laymen. The net result, we must confess, is rather disappointing; for no particularly new facts were brought out, and there was a most placid unanimity of opinion to the general effect that college athletics form a beneficent factor in education. It hardly requires a special meeting of savants to determine this point. What one would like to know is the amount of evil connected with athletics, and how this can be prevented. The directors of gymnasia, trainers and physical educators, furnish us interesting reports showing the increase under training of the circumference of the arm and the expansion of the chest. But they do not tell us of the hypertrophied hearts, crippled limbs, and lowered scholarship. Among the 3,000 students at Harvard, we gather from Dr. Conant that about 400 engage actively in college athletics. He gives us a list of about 70 foot-ball injuries per year among some of the latter. These are rather inadequate data. It has often been urged that one evil of competitive athletics lies in the fact that the system practically puts on the shelf the weaker men, who have no special aptitude or inclination to athletics, but who especially need physical culture. All that is left to these are the inanities of wooden dumb-bells, wands, and clubs, things which no self-respecting intelligence will long put up with.

It is admitted that college athletics tend to disparage scholarship, but to what extent no one seems to know.

In fact, the only suggestive thing in the whole discussion is a remark by the Mayor of Cambridge, who expressed surprise that college authorities do not personally supervise and teach athletics, since they admit that physical culture is of so much importance. The exercises of intellectual culture are rigidly controlled, but physical culture is left largely to the student's inclinations or whims.

THE DOCTOR AND THE BICYCLE.

SHALL the doctor ride a bicycle? It is too late for an answer to this question. He already does it. The wheel has evidently come to stay, as a source of recreation to the busy physician, if not used by him as a means of locomotion in making his rounds. It is probably even too late for us to discuss the advisability of the professional sister striding the two-wheeled steed. She has not only taken to it most kindly in common with many of her sex, but has already begun to give them practical information concerning the proper way to ride, so as to gain the greatest benefit with the least danger of injurious effect. We have already called attention to Dr. Laura Liebhardt's discussion of the question before the Colorado State Medical Society, in which the advice is given, among other things, not to mount during the first days of the menstrual flow, or at least only for short hill less rides.

Undoubtedly injury may be inflicted upon the perineal

region by a faulty saddle-pressure too long kept up and accidents en route; but taking into consideration the amount of bicycling now indulged in, it must be admitted that the physician is not often called upon to prescribe for any results of injudicious riding. On the other hand, those who have carefully watched this mode of exercise from its therapeutic side, must have observed the benefit derived from its proper use in many conditions of non-health. In its present perfected state, the pneumatic-tired "safety" is a very different machine from the "velocipede" of the sixties and the "ordinary" of the transition period of its evolution; and it is now, for the first time in the history of two-wheeled travel with the rider as the propelling force, that the serious attention of the medical profession is demanded.

In just how far we are justified in prescribing or forbidding it—especially for young girls; what are the dangers to warn against; at what point does benefit cease and injury begin? These are questions for the physician to decide—not from his own narrow views and preconceived ideas as to the fitness of things, but from a true scientific study of the question. For himself he can decide whether he considers it dignified or judicious to visit his patients awheel. If the distance is too great for him to arrive in a presentable condition, he had better stick to his chaise. If the case is one of urgency and he can get there quicker, he need not fear the condemnation of the anxious sufferer.

But whether he goes adriving, ariding, awheel, or a foot, the doctor must bless the bicycle, for it has done more, and probably will do more, for the cause of good roads throughout the country than any other one thing, and no one knows better the necessity of good roads than the doctor.

PHYSIOLOGICAL EPOCHS THAT PREDISPOSE TO INSANITY.

At a recent meeting of the Medical Society of the County of New York, a paper read by Dr. William M. Spratling, on the "Physiological Epochs that Predispose to Insanity, with Observations on the Management of Each," presented in clear and definite form certain facts too often overlooked and ignored by the general practitioner and the public at large. The grave responsibility of treating insanity in its incipiency rests in greater degree upon the physician in general practice than upon the specialist in diseases of the mind. The family doctor sees usually the first signs of incipient mental disorder, when its early recognition and proper treatment may secure the happiest results.

Mercier concisely sums up the causes of insanity in this way: Insanity is, in mathematical terms, a function of two variables; that is too say, there are two factors, and only two, in its causation; and these factors are complementary. Both enter into the causation of every case of insanity; and the stronger the influence of one factor, the less of the other factor is needed to produce the result. These factors are heredity and stress. A study of the various states of mental instability arising directly from physiological epochs, proves conclusively and without variation that heredity and stress, with their subdivisions, constitute the only etiological factors. There are six distinct epochs at which insanity may appear, all but one being strictly physiological in the order and nature of their occurrence. This one, the epoch of heredity, may be called patho-physiological. Early childhood, puberty, maternity, the epoch of heredity, the menopause, and senility, are these fixed times in which stress may serve to destroy mental health. Early childhood is the period of life beginning with the seventh month and ending with the beginning of the seventh year, and may be in itself said to predispose only indirectly to insanity through its accidents and incidents. Puberty in the female extends from the thirteenth to the fifteenth year; in the male, from the fourteenth to the sixteenth. The third physiological epoch covers the entire childbearing period, from the fifteenth to the forty fifth year. Insanity occurs more frequently during the first than during the latter half of this period. The epoch of heredity has not had special attention called to it by writers in this country, though it is an important and variable one. It embraces that critical period of the life of any individual whose ancestors have been accustomed to exhibit evidences of insanity on reaching a certain age. Régis uses the term phrenasthenia to designate and include all forms of inherited insanity. The fifth epoch is that of the climacteric, from the forty-third to the forty-fifth year. Exceptionally, the time may be extended a little either way. The changes that now occur are the most clearly perceptible of those of any epoch, and lead oftener to mental instability. Senility is the last epoch, old age; and it is interesting to note that, when the preceding epochs have not been strictly physiological, pathological conditions of mind are apt to appear in extreme old age.

Early childhood presents the possibility of many accidents and incidents that may serve to render the child mentally unsound in the future. Gowers is authority for the statement that one-eighth of all the cases of epilepsy begin during the first three years of life; and adds that, with rachitis as a combining cause, seventy-five per cent. of all cases of epilepsy that begin during the first three years of life are due to infantile convulsions ascribed to teething. Here the various tendencies of an inherited taint change a perfectly physiological process, that ought to be free from danger to the child, into a period fraught with influences of a most pernicious kind. Syphilis, chronic alcoholism, insanity, or epilepsy, in the parent, stamps on the child's nervous system a congenital instability that unfits it to pass unscathed through the serious disturbances that mark the steps of growth and development. Dentition alone is probably never a cause of genuine epilepsy; what it does give rise to are epileptiform convulsions that in time take on the character of true epilepsy. That insanity often follows epilepsy is well known. Clouston states that cases of prolonged delirium ending in idiocy, and arising out of the ordinary convulsions of dentition have come under his observation. And such cases have also ended in true epilepsy, followed by insanity. Adolescent insanity has appeared so often, as well as other forms, in persons earlier the victims of epilepsy, that it is impossible to regard the two as coincident.

In the *Journal of the American Medical Association* for August 18, 1894, Wilmarth gives some interesting facts concerning idiocy, epilepsy, imbecility, and insanity, as he studied them at the Pennsylvania Institute for Feeble-minded Children. Out of one thousand

cases admitted to the institution, he found that there were three hundred and twenty-two whose condition required medical treatment before entering, and whose afflictions were of such a nature as to indicate that medical treatment would possibly bring about a cure. In this list, all cases not amenable to medical treatment are excluded, together with cases in which congenital defect was noted before the sixth month, or just before the commencement of dentition. In seventy-five cases out of the three hundred and twenty-two, the disorder had developed during the spasms of dentition; in two cases, before the sixth month; in twenty-nine, between the sixth and twelfth; in twenty-five, between the twelfth and eighteenth months; and between the eighteenth month and the twenty-fourth, nineteen cases are recorded as first showing evidences of mental disease. The growth of a little child's brain is rapid up to the seventh year, and anything which interferes with its nutrition is a serious matter. Besides dentition, traumatism, blows or falls on the head, the effects of excessive heat, mental shock, fevers of specific origin, and structures and malformation of the genital organs, are causes that act unfavorably upon the organism and threaten to disarrange its more highly developed parts.

The excito-motor exaltation during the first dentition has its parallel in the explosive condition of the nerve-centres, in the higher plane of cerebral activity, during the evolution of the generative function and of the sexual divergence of early adolescence. Such epochs may be characterized as the search-lights of psychiatry, since they serve to reveal weak spots in the mental organization. The mental disorders that so frequently develop at this age, are due to indirect stress of internal origin. Pubescent insanity may develop anywhere between the ages of fifteen and twenty-two. The epoch of puberty is attended with more danger to the female than to the male, the time is shorter, and the shock is greater. Insanity in the female at this epoch is essentially an acute neurosis, acute mania being its commonest form. Acute mania is also the commonest form of puerperal insanity. Hallucinations appear in about one-quarter of the cases in both sexes, those that are visual and aural predominating. Delusions of poisoning exist frequently, and spiritual delusions are not uncommon. When uncomplicated by hereditary taint, the prognosis is good. Nearly four-fifths of persons thus afflicted recover. Early removal from home is best. Nourishment easy of digestion should be given, and the secretory and excretory organs should receive special attention, since they are liable at this period to sluggish action. Sleep must be secured by open-air exercise and by hypnotics; and narcotics and sedatives avoided. Menstrual irregularities, anæmia, etc., require the strictest hygiene, and the use of carbonate of iron, extract of nux vomica and rhubarb in pill form, malt extract, etc.

Pregnancy, labor itself, and lactation, have more important relations to insanity than other physiological epochs. Insanity during pregnancy is more frequent among women about to give birth to an illegitimate child. Mental anomalies vary all the way from simple morbid appetites to well-marked melancholia with suicidal impulses. Transitory frenzy during labor appears as the forerunner of puerperal delirium. Infanticide and suicide are acts common to the subjects of this condition. Mental derangement may come on suddenly after childbirth or develop gradually after evidences of nervous exhaustion, most frequently appearing as acute mania. Begin treatment with a saline aperient, and search for and remove causes of fever. The condition of the blood may require iron; but none of the chalybeate preparations should be used till all traces of acute excitement have subsided. The infant must be removed from the mother's care. The mother's diet must consist of milk, beef-tea, broth, and eggs, administered in small quantities at frequent intervals. To secure sleep, the following may be used: chloral, bromide of potassium, sulfonal; paraldehyde, two-drachm doses, or more if required, in a small quantity of port wine. Warm baths often suffice to produce refreshing sleep, and, whenever possible, deserve a trial before drugs are given.

The fifth physiological epoch is the menopause. Psychic manifestations are well marked. Whenever there is inherited tendency to mental disease, or when there have been earlier attacks of insanity during one of the former epochs, the menopause has added dangers. Climacteric insanity, Skae characterizes as a monomania of fear, despondency, remorse, hopelessness, passing occasionally into dementia. Over half of all cases are of the depressed type. Treatment consists mainly in a tonic regimen, out-door life, strict attention to diet, and change of surroundings. Iron and arsenic are required, artificial feeding is often necessary, and sleep must be secured by hypnotics. Chloral hydrate, in a single large dose, and paraldehyde, are the best. Senile mania and senile melancholia occur as distinct disorders. The most satisfactory drug for the treatment of insanities incident to old age is opium, beginning with small doses. The danger of establishing the opium habit is less than if the patient were in the prime of life. Persistent insomnia and great restlessness are overcome by opium, which seems to have as powerful an influence over humanity in its second childhood as it has during humanity's earliest years.

MEDICAL UNIVERSITY EXTENSION.

We have often wondered why some active and philanthropic mind did not devise a scheme for applying "University Extension" to medicine. And now we find that it has been done by an association of eminent English physicians, including Drs. Clifford Allbutt, Sir W. H. Broadbent, John Cavafy, J. F. Goodhart, T. H. Green, Hughlings Jackson, S. Wilks, Sir James Paget, Sir J. M. Humphrey, and Mr. Jonathan Hutchinson.

They term their movement the "Clinical Research Association." It proposes, as we understand, to furnish the general practitioner a convenient means of having all forms of bacteriological, chemical, and microscopical information made accessible to him and his patients.

THE RECOGNITION OF MERIT.

The Germans have their jubilees, and the English their "presentations." We notice in a recent issue of *The Lancet*, that Dr. Walter Murray was presented with a clock for his bravery in going to the rescue of a policeman. Also, that Dr. Symington has been presented with a tea-tray for causes not stated. The habit of giving some

formal recognition to conspicuous merit or long professional service, is surely a most praiseworthy one. We wish that in this country something of the kind might be done. With us the doctor gets recognition sometimes after he is dead, but that is, after all, not so satisfactory to the person most concerned.

THE CZAR'S DISEASE.

To such medical men as have studied the symptoms of the disease of the Czar, as they have been reported in the vague and meagre official bulletins, it must be apparent that the only way to reconcile seemingly conflicting accounts, and draw reasonable conclusions therefrom, is to assume that the diagnosis made by Professor Leyden is the correct one. Contracted kidney, as is well known, is a very common affection in persons addicted to the pleasures of the table and the excesses of the cup. The general condition of the distinguished patient, his corpulency, and attendant lack of vital energy, make him a fit subject for this form of renal disease. The distressing symptoms of paroxysmal cardiac dyspnœa, due to feebleness of compensatory cardiac effort, the pulmonary complications associated with pleuritic effusion, and the general weakness and anasarca caused by the lowering of arterial pressure, are of ominous gravity, and tend in the direction of a probably speedy dissolution. Under the circumstances, it will not be surprising to learn of the appearance of apoplexy, convulsions, or coma, or of an equally sudden termination in syncope, or pulmonary œdema.

A NEW CURE FOR PERNICIOUS ANÆMIA AND LEUCOCYTHÆMIA.

"While sitting alone, and in profound sorrow, in my library, on Sunday morning the 29th of April last, I suddenly saw a great light." It is in this somewhat dramatic way that Dr. I. N. Danforth, whose wife was suffering from pernicious anæmia, begins his description of a new method of treating that disease. The light which he saw was reflected from the following paragraph in a London journal: "Professor Frazer, of Edinburgh, read a paper to the Section of Medicine" (of the Eleventh International Medical Congress, at Rome) "on the Effects of Bone Marrow in Pernicious Anæmia, which attracted considerable attention. He gave particulars of a case in which at the beginning of the disease the hæmatocytes numbered 1,000,000 per cubic millimetre, and the hæmoglobin twenty-five per cent. After a month's treatment, first with iron, then with arsenic, afterward with salol, no appreciable improvement was manifested. At the end of that time bone marrow was administered with remarkable results. The patient gradually improved, and in two months the blood had a composition of 4,000,000 hæmatocytes, and the hæmoglobin had risen to eighty per cent. This case shows, so far as a single case can, that in bone marrow we may perhaps have an effective remedy for what has hitherto been practically held to be an incurable disease."

Dr. Danforth immediately got some bone marrow and began feeding it to his patient, whose condition, despite everything that had been tried, was desperate. She at once began to improve, and in four or five months was comparatively well.

After a time, instead of giving the marrow in its natural state, he cut up several ribs and allowed them to soak in glycerine. He then made the following mixture:

℞. Liq. potas. arsenit. ..... ℥ ijss.
Acid phosphate ..... ℥ iij.
Ext. bone marrow ..... ad ℥ viij.
M. Sig.: ℥ ij. after each meal.

The addition of the arsenic robs the bone marrow of some of the credit. This addition was not made, however, in Professor Frazer's case.

We note also that Dr. W. G. Bigger reports, in a London journal, a case of leucocythæmia in a boy aged twelve. The patient was given three or four slices of bread daily, on each of which the raw bone marrow was thickly spread. The improvement in the boy's condition after the first week was "little short of marvellous." The anæmia and jaundice disappeared, and the skin and mucous membrane acquired a healthy color. The symptoms due to the anæmia at the same time passed off, and in three weeks the boy was able to walk about without shortness of breath or palpitation. The temperature also became normal, and has remained so. *Pari passu* with this improvement in the general symptoms, the spleen diminished in size, so that by the end of a fortnight the lower edge had receded to a level with the anterior spine of the ilium, and the inner edge did not extend beyond the middle line.

The boy eventually became entirely well. Both the cases reported are apparently examples of cures of obstinate and dangerous diseases. If we have a remedy for them in bone marrow, therapeutics has made a remarkable advance.

A NEW WAY TO ADVERTISE.
